The great divergence of opinion as to the rating of permanent disability in industrial cases often makes us the laughing stock of those familiar with the transactions of the Industrial Commission. I believe it is entirely possible that, through the agency of the members of the Surgical Society and those practicing orthopedic surgery and especially those who major in traumatic surgery, some scale could be arranged whereby this discrepancy would no longer exist. At present the law states exactly what the disability is for certain amputations. They might readily specify what the disability would be for the loss of varying degrees of function of the elbow and especially when the elbow is ankylosed in a favorable or an unfavorable position. Some sort of a standardization ought to be possible.

The fact that it is estimated that 300,000 persons in the United States have cancer at the present time and that theoretically early cancer is curable, places the cancer problem foremost among surgical topics. The early diagnosis and standardized treatment of cancer in its various locations may very readily constitute another symposium of surgical essays.

In closing, it may not be amiss to call attention to the fact that we are approaching our tenth anniversary. I think that even at this time we might begin to make

plans for some very special events to celebrate. For instance, one or two special meetings with extraordinary speakers or clinics. You will all remember that years ago Minneapolis had a clinic week at which time all of the doctors of the state were invited to attend the scientific programs and clinics. For some reason or other this clinic week was discontinued. I feel that our society might invite all of the doctors throughout the state to come to Minneapolis for a two-day surgical program put on entirely by our Surgical Society in which papers could be rendered by its members, together with operative clinics. As quoted in our constitution, the purpose of our society is both scientific and social. I believe that a clinic week would fulfill both of these purposes and would reflect much credit upon our society, and let the rest of the state know the excellence of the surgical work that is being done in Minneapolis.

Dr. Kenneth Bulkley reported the following two cases of malignancy of the large bowel in young people.

I would like to report briefly the two following rather similar cases which I feel sure would be of interest. Both of the patients are still in the hospital. Both are cases of malignancy of the large gut in relatively young people.

The first case is that of a boy twenty-four years of age with indefinitc abdominal symptoms of which the most predominant was gas. There has been practically no pain, no loss of weight, no true obstructive symptoms. Except for *x*-ray findings his physical examination was negative. A barium enema could not be forced beyond the hepatic flexure. Barium by mouth gave no positive findings other than excessive peristalsis in the ascending colon. Stool examination was negative. At operation an annular carcinoma of the hepatic flexure was found and resected. No metastases anywhere were evident. A typical Mikulicz operation was done and a few days ago I closed his fecal fistula.

The second case is that of a boy of twenty-nine upon whom I operated this evening. This boy three years ago had had a clean appendectomy. Ever since then he has had much abdominal gas, both stomach and intestinal. He has lost no weight; he has had no pain referable to his abdomen. This morning he vomited his breakfast and had abdominal cramps. We started an *x*-ray study on this boy but due to increased distention and persistent vomiting it was not carried to a completion and it seemed wiser to operate on him without further investigation, the operation being done under the diagnosis of intestinal obstruction probably due to bands. Inexcusably, no rectal examination was done and it is largely to point out this error that I report this case. The diagnosis seemed so clear as to the cause of obstruction that the rectal examination was omitted. At operation, however, this boy was found to have a large carcinoma of his rectum fixed to surrounding structures and lying immediately above the levator ani muscle. Again no metastases could be found. The mass had ulcerated through and perforated on its anterior surface with a resulting accumulation of foul smelling fluid in the true pelvis. There were a few adhesions from his old operation but these were not responsible for his obstruction. The lower abdomen was drained and through a left rectus incision a sigmoidostomy was done.

These cases seemed of interest both from a viewpoint of diagnosis and from a viewpoint of rarity. In the first case the differential diagnosis lay between a carcinoma of the hepatic flexure or a tuberculosis of the cecum and ascending colon. In the second case the diagnosis of the cause of the obstruction was wrong. It should have been made without any difficulty had a rectal examination been done.

Dr. S. R. Maxeiner presented the following case of cleft palate:

Miss K. F. is a sixteen-year old student.

Family history is entirely negative, no history of tuberculosis, cancer or congenital deformity being obtained.

Past History: Patient has never been seriously ill and has never had any severe accidents.

Present Complaint. Patient was born with a cleft palate involving the posterior four-fifths which was operated upon twice when the patient was two years of age, with almost complete failure. Patient came to us with a large rounded hole in the roof of the mouth, approximately 2 cm. wide and 3.5 cm. in length. Examination was entirely negative, patient being otherwise well developed and physically and mentally normal, except for very greatly enlarged, cryptic tonsils.

Operative Procedures: On November 4, 1929, tonsillectomy was performed and the patient sent home with instructions to report six months later for operation upon her palate.

Stage 1. On April 15, 1930, under local anesthesia, the mucoperiosteum was separated on both sides of the cleft, extending outward to the teeth and running forward to the alveolar arch. This completely loosened the entire palate and the edges of the cleft could be readily approximated without tension. The flaps were penetrated on both sides at the teeth and a packing of iodoform gauze gently placed underneath the flaps. No attempt was made to suture the cleft.

Stage 2. On April 22, 1930, under local anesthesia the flaps were again lifted and the edges pared and approximated without tension with dermal sutures. One mattress dermal tension suture tied over buttons was also used to prevent any traction upon the line of suture. This stage of the operation proceeded with so little effect upon the patient that we determined to attempt to lengthen the posterior edge of the palate, which was altogether too short and was the only part that had been successful at the time of the original operation. After the technic of Brophy, the posterior edge of the palate was freshened. Both pillars on both sides were cut three-fourths of the distance through the palatopharyngeal muscles and the freed upper edges of these flaps were brought together as recommended by Brophy, so that the palate was lengthened three-

quarters of an inch. A second tension suture was introduced and anchored over buttons.

This patient seems of special interest, inasmuch as she has had two previous operations in infancy with almost complete failure. The present operation has been followed by primary healing throughout. The opening in the palate has been completely closed and the palate has been lengthened about three-fourths of an inch. The sutures, which are still in place, will be removed tomorrow, the eleventh day. I believe that we must attribute a large part of this success to the use of the delayed flaps or the two-stage operation, as recommended by New.

Following the scientific meeting Dr. A. T. Mann, the new president, was escorted to the chair and conducted a brief business meeting.

The meeting adjourned until October, 1930.

THE RELIABILITY OF GUINEA PIG INOCULATIONS IN THE DIAGNOSIS OF TUBERCULOSIS: Abstract of a paper by T. B. Magath and W. H. Feldman, read before the Trudeau Medical Society, Rochester, Minnesota, March 29, 1930; to be published in American Review of Tuberculosis. In order to evaluate the reliability of inoculation of guinea pigs in the determination of obscure tuberculous infections, a study was undertaken to ascertain, first, if the tissues of guinea pigs which failed to reveal at necropsy gross tuberculous lesions contained histopathologic evidence of tuberculosis, and second, what should be considered of significance in the histologic examination of tissues of guinea pigs in minimizing possible diagnostic errors.

Use was made of material consisting of catheterized urine from the ureters and bladder, tissues from bones and joints, thoracic fluids, and miscellaneous tissues obtained from the Section on Clinical Pathology of the Mayo Clinic. The material which was negative for *mycobacterium tuberculosis*, by the usual microscopic examination, represented 158 consecutive cases.

Two guinea pigs were given injections with portions of each specimen, one subcutaneously and one intraperitoneally, and those living at the expiration of eight weeks were killed and necropsy was performed. The presence or absence of a tuberculous infection was determined as a routine by the gross appearance of the viscera. By this procedure, twenty-one of the cases were eventually considered tuberculous. The liver and spleen of 201 of the guinea pigs which died or were killed subsequent to inoculation, and which were considered nontuberculous at the time of necropsy, were examined by appropriate histologic methods for possible lesions of tuberculosis.

Although occasionally tissue was found which possessed alterations simulating in some degree the morphologic reaction to the organism of tuberculosis, the failure to demonstrate the causative organism was considered decisive in designating each of these lesions as nontuberculous.

In a study of the reactions of tissue subsequent to a definitely tuberculous infection it was found that undue significance should not be placed on the cellular aspects of the lesion. The presence of giant cells of Langhans type may be particularly misleading. In guinea pigs affected with tuberculosis, and on which necropsy is done eight weeks subsequent to exposure, giant cells are not an essential part of the lesions and usually are absent. By appropriate staining methods, acid-fast bacilli can be found among the cells of the cellular detritus in practically every instance in which the lesions are those of tuberculosis, and failure to observe acid-fast organisms in lesions which are typically not those of tuberculosis is presumptive evidence that the condition is nontuberculous.

The data obtained in this study have established the reliability of inoculation of guinea pigs in the diagnosis of tuberculosis. Animals which live eight weeks subsequent to injection and which fail to reveal gross lesions of tuberculosis at necropsy, in all probability do not possess a tuberculous infection, and the routine histologic examination of such tissues is not necessary. When a histologic study is done, the presence or absence of acid-fast bacilli rather than the specific nature of the cellular reaction constitute the most dependable criteria in reaching a decision.

ROY N. ANDREWS,
MANKATO CLINIC, MANKATO

EPITUBERCULOSIS: Phillip E. Rothman, M.D., Los Angeles (Arch. of Ped., March, 1930, Vol. XLVII, No. 3). Epituberculosis consists of a large area of pulmonary consolidation associated with enlarged mediastinal tuberculous glands. The consolidation may

persist for many months, but ultimately resolves with little or no permanent lung damage. The onset is insidious and none of the case reports include early signs or symptoms of any constancy. The child's general condition is fairly good and there is usually no dyspnea, polypnea, or diminution in the degree of expansion of the affected side.

The physical signs are those of consolidation with dullness, slightly distant tubular breathing, but with a great paucity of râles or even none at all. An ordinary pneumonic process is suspected. The tuberculin test, however, is invariably positive and the *x*-ray shows a wide mediastinal shadow in addition to a homeogeneously dense consolidation.

The insidious onset, positive tuberculin test and long duration speak for epituberculosis. The absence of tubercle bacilli in the sputum is a very helpful point in differentiating this condition from caseous pneumonia.

Some have maintained that it represents an allergic response in patients previously infected with tuberculosis; whereas, others feel that it is an atelectatic or collapsed portion of lung resulting from regional swelling of bronchial lymph-nodes with lymphatic stasis or actual pressure on the bronchi. It is generally believed that the process is simply an inflammatory reaction about a tuberculous focus in either the mediastinal glands or lung tissue, and that it contains no tubercle bacilli. In this respect it is non-specific, but it is specific in the sense that it is always secondary to or associated with a tuberculous infection.

R. N. Andrews, M.D.

TUBERCULOSIS IN INFANCY AND CHILDHOOD: Nursemaids as a Source of Infection—Henry Dietrich, M.D., Los Angeles (Arch. of Ped., March, 1930, Vol. XLVII, No. 3). It is only during the past few decades that we have begun to realize the frequency and gravity of tuberculosis infections in the young child. Tuberculosis is a disease of childhood. It generally begins in childhood and therefore our preventive measures must be aimed particularly at this period of life. The tubercle bacillus, once implanted in the body of the child, finds a most fertile soil for its growth and, as we know, even if apparently overpowered by the body forces, may at any time in the future light up and blight or destroy a useful life.

The following four facts about tuberculosis are now well established: (1) Tuberculosis is an acquired and therefore preventable disease. (2) The tuberculous patient is generally the source of infection. (3) The great majority of infections in man are air-borne. (4) The younger the individual the greater the susceptibility and the more dangerous the disease.

It may require only a few hours a day of association with an open tuberculosis to infect and perhaps destroy the young infant or child. A tuberculous nursemaid or governess not only is a menace to her own household but frequently also comes in close contact with many of the children in the neighborhood.

Today we demand a tuberculin test of our dairy cattle. We ask for a health examination of the employees of our certified dairies and of many employees in other industries. Boiling the milk will destroy the tubercle bacillus. Nothing except removal of the person with a tuberculous focus will protect the child against infection. We must demand a health examination of all persons making it their business to care for or help care for infants and children.

ARTHUR C. DEAN
HOT SPRINGS, SOUTH DAKOTA

RELIEF OF NASAL OBSTRUCTION IN CHILDREN DUE TO DEVIATION OF THE SEPTUM: W. W. Carter, M.D., New York City (Ann. of Otol., Rhin. and Laryng., Vol. 39, No. 1, pp. 199, Mar. 1930). The author mentions the difference of opinion among our ablest rhinologists as to the method to be employed for relief of nasal obstruction, and the extent of operative interference permissible at an age before nasal development is complete.

The author feels that the extensive removal of the septum in the very young is not the procedure of choice. He believes that the septum is a very prominent factor in the development of the flattened infant nose into the prominent adult nose. For that reason he does not accept the complete submucous resection of the septum as the operation of choice.

He cites the dynamics of nasal development and shows that the septum is by far the most important factor. For that reason the septum must be preserved to the greatest extent consistent with relief of obstruction.

His method follows: Ether anesthesia, the usual vertical submucous resection incision is made and the mucosa elevated on that side. Then he inserts the submucous knife into the sac and makes two parallel incisions from behind forward on either side of the apex of the deflection. These incisions extend only through the cartilage. Next this narrow strip of cartilage is removed. An incision is next made through the upper segment parallel with the dorsum of the nose and the entire length of the deflection. A corresponding incision is made below and parallel with the floor of the nose. These two incisions destroy the resiliency of the cartilage. Next the septum is lined up in its normal vertical position. Then gold wire splints are introduced into each nostril and moulded to fit the case. These splints should remain in the nose for 10 days, and the nose cleansed daily with an alkaline solution.

Immobilization of the nose with a lined copper splint is essential.

Arthur C. Dean, M.D., F.A.C.S.

MASTOIDITIS WITH GASTROINTESTINAL DISTURBANCES IN INFANTS: John W. Carmack, M.D., Indianapolis (Ann. of Otol., Rhinol. and Laryngol,. Vol. 39, No. 1, p. 75, March, 1930). The author says that since 1921 the relation between gastro-enteritis and mastoiditis in infants has been recognized by Renaud, Byfield and Dean. There has, however, been some conflicting opinions as to the advisability of mastoid drainage externally, as well as the proper time for interference. He divides these cases into two groups: First, in which there is an acute respiratory infection, including the middle ear and mastoid, together with a violent enteritis, dehydration and toxemia; second, in which there is mastoiditis, but it is doubtful whether the gastrointestinal disturbance is due to actual infection of the bowel or to a toxic disturbance. This latter group has much less violent symptomatology of the gastrointestinal tract.

In twenty-eight infants, twenty-one were operated on for both mastoids at the same time; of the seven remaining it was necessary to operate on the other side later in four. The most unsatisfactory results were obtained in the patients operated on during the active stage of a dehydrating diarrhea and high temperature. There is much to be desired in the standardization of our ideas as to the time for operation and the preoperative and postoperative treatment. The diagnosis and proper course to pursue can only be determined by the closest coöperation between the otolaryngologist, the pediatrician and the roentgenologist.

The appearance of the drum membrane is not always a safe criterion of the pathology inside. Few, if any, infants with gastrointestinal disturbances have normal drum membranes. External mastoid signs have been notably absent. *X*-ray plates are valuable but very difficult to interpret. It seems that the normal mastoid space is larger than formerly believed in the first and second years of life. Cell formation has been seen frequently as early as one year of age.

The most satisfactory time for operation is after the acute storm subsides. Preoperative treatment consists in restoring the body fluids, and blood transfusion where hemoglobin is under 70 and red blood cells under 4,000,000.

All operations are done under novocaine and codeine. The wound is left open and heals by granulation. Postoperative care is supportive and stimulating. Fluid and food are pushed. Repeated transfusions if necessary.

CONCLUSIONS

1. Mastoiditis may occur coincidental with an acute respiratory and gastrointestinal infection and may become an important factor in the outcome of the case; in others, the mastoid may become involved and remain as a focus of infection producing gastrointestinal symptoms of a toxic nature or subsequent intestinal infection.

2. Surgical intervention cannot be decided upon intelligently without close coöperation between the pediatrician, the otolaryngologist and the roentgenologist, but no mastoid should be opened without clinical evidence of disease in the mastoid space.

3. Adequate preoperative and postoperative treatment is of vital importance.

4. All infants with marked or continued gastrointestinal disturbance should have careful ear examinations, and if pathology is found, early and free drum incision should be made. If the mastoid is involved and satisfactory improvement is not had by ear drainage a mastoid operation is indicated.

5. Operation, except in the occasional case, should not be attempted during the violent gastrointestinal crisis.

MAYO CLINIC, ROCHESTER

ROENTGENOGRAPHY OF THE KIDNEYS AND URINARY TRACT BY MEANS OF INTRAVENOUS INJECTION OF A NEW CONTRAST MEDIUM, UROSELECTAN: M. Swick (Klin. Wchnschr., November 5, 1929, p. 2087). While investigating the excretion of Selectan-Neutral, which had been used therapeutically in the treatment of different coccus infections, it was discovered that excretion was more marked through the kidneys than through the bile. The first results by intravenous injection in animals were only sufficiently satisfactory to indicate the possibility of the method if the affinity for the kidney and the solubility of the substance could be improved. Oral administration in man was not successful. Continued investigation with the coöperation of the chemical institute finally evolved a substance which answered the requirements of safety, free solubility and marked excretion by the kidneys. This has been named Uroselectan. The iodine content of this drug is 42 per cent. It is well tolerated intravenously by mice and squirrels and when injected intravenously in man in proportionately much smaller amounts, yields very satisfactory pyelograms. The density of the picture depends directly on the condition of the kidney, as does also the time at which the best picture is obtained. The latter varies from one to two hours in the presence of good kidney function to 24 or even 32 hours in poor function. When function is very poor, no shadow is obtained. Whether normally or slowly excreted, the drug is not demonstrable in the blood after fifteen minutes. What becomes of the substance when not excreted has not been determined. In the clinical tests there were no deleterious effects of consequence. Death nineteen hours after injection in a girl of ten was shown to be due to the severe and advanced nature of the pathological conditions. The conclusion is

that Uroselectan is remarkably well tolerated in all surgical kidney diseases.

After intravenous administration, performance of which is very simple, films are taken at intervals, depending upon the rapidity of excretion. Fluroscopy was also employed.

Reproductions of eight typical urograms are included. EDWARD SCHONS.

CLINICAL TRIAL OF UROSELECTAN: A von Lichtenberg and M. Swick (Klin. Wchnschr., November 5, 1929, p. 2089). This new substance promises extensive clinical applicability of intravenous urography. The method offers in cases of sufficient kidney function satisfactory urography; in all cases a roentgenological function test, as well as a new chemical function test.

All cases examined with Uroselectan were controlled by direct pyelography and the results compared. Of 84 cases examined, the results were checked operatively in 35 cases and by autopsy in 1 case. The results with Uroselectan were technically successful and the pictures serviceable for diagnosis. No shadow indicated always either absence of the kidney or marked impairment of kidney function. The shadow was thus absent in advanced kidney tumor, pyonephrosis, severely infected obstructed kidney; also in marked cardiac insufficiency. In all cases of marked or total obstruction if accompanied by infection the shadow was absent. In cases of hydronephrosis, ureteral stone and high grade renal disease due to stone, excellent pyelograms were obtained. A very interesting case of closed tuberculous pyonephrosis showed cavities in the upper half of the kidney.

The method was used in nearly all forms of primary and secondary surgical kidney pathology. In prostatic hypertrophy the dilatation of the pelves and ureters was well shown.

Prof. von Lichtenberg is very enthusiastic about the possibility of studying the function of the ureters.

In 61 out of 84 cases examined, fully sufficient information for the preliminary handling of the case was obtained, cystoscopy, ureteral catheterization and pyelography being necessary in the remainder. In 75 cases information as to function was sufficient to determine the operative indications. In all cases was the examination of the case expedited and simplified and in 70 per cent could more radical examination be avoided.

Indications for intravenous pyelography are given as follows: (1) Cases where direct cystoscopy, ureteral catheterization and pyelography cannot be done because of anatomical, pathological or technical reasons; (2) cases of obstruction where direct injection can be done only to the point of obstruction; (3) where the ordinary method is risky.

No contraindications are at present mentioned, but it is stated that so far the ureters are often better shown by the old method.

EDWARD SCHONS.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

TREATMENT OF SKIN DISEASES—IN DETAIL. Noxon Toomey, M.D., F.A.C.P. Late instructor in Dermatology, St. Louis University, Major and Surgeon, 138th Infantry, Missouri National Guard, Dermatologist to the Terminal Railroad, sometime editor of the Urologic and Cutaneous Review. 512 pages. Cloth, $7.50. St. Louis: The Lister Medical Press, 1930.

BULLETIN OF THE NATIONAL RESEARCH COUNCIL, No. 73. A survey of the Law Concerning Dead Human Bodies. George H. Weinmann. Issued under the auspices of the Committee on Medicolegal Problems, National Research Council. 199 pages. Paper, $2.00. Washington, D. C.: National Research Council, 1929.

UTERINE TUMORS. Charles C. Norris, M.D., Professor of Gynecology and Obstetrics and Director of the Department, University of Pennsylvania; Gynecologist and Obstetrician, Hospital of the University of Pennsylvania, Henry Phipps Institute of the University of Pennsylvania. 251 pages. Illus. Price $3.00. New York: Harper & Brothers, 1930.

LECTURES ON COLONIC THERAPY. O. Boto Schellberg. 55 pages. Illus. Price $2.00. New York: The Oboschell Corporation, 1930.

DIABETES—Directions for Treatment by Insulin and Diet. Benjamin F. Smith, M.D. Physician and lecturer to St. Joseph's Infirmary, Hermann Hospital, and Jefferson Davis Hospital, Houston, Texas. 223 pages. Price, cloth $2.00. New York: D. Appleton & Company.

TUBERCULOSIS AMONG CHILDREN—J. Arthur Myers, Ph.D., M.D., F.A.C.P., Chief of Medical Staff Lymanhurst School for Tuberculous Children, Associate Professor of Preventive Medicine, University of Minnesota. Chapters by C. A. Stewart, M.D., Ph.D., and Paul W. Giessler, M.D., of the University of Minnesota. 208 pages. Illus. Cloth, $3.50. Springfield, Illinois: Chas. C. Thomas, 1930.

INJECTION TREATMENT OF INTERNAL HEMORRHOIDS—Marrion C. Pruitt. 137 pages. Illustrated. Price $3.00. The C. V. Mosby Co., St. Louis, 1929.

In this book there is a general discussion of hemorrhoids, including anatomy, etiology, prophylaxis, history, etc. The author expresses his own opinion and in-

cludes that of other authorities on the subject. A classification of hemorrhoids is given, and symptoms and other conditions of the anus are considered.

The second half of the book is devoted to discussion of the injection treatment, giving indications, contraindications and various solutions used. The author's idea of treatment is clearly given and necessary illustrations are included; also a series of case reports.

The book lives up to its title and covers the subject in such a manner so as to make it more practical than theoretical.

ARTHUR E. STOECKMANN, M.D.

PHYSIOLOGY FOR NURSES: W. G. Christian and Charles C. Haskell. Second Edition. $2.00. St. Louis: C. V. Mosby Co., 1929.

A rather complete volume that may be used if a nurse is familiar with anatomy.

It is well illustrated and particular attention has been paid to the chemical aspect. The volume is too brief, however, and not enough attention has been given food digestion and nervous system.

This volume could be used to advantage for review.

INEZ PEYTON.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

WANTED—Position as assistant to doctor or dentist. Graduate nurse, experienced typist. Address D-69, care MINNESOTA MEDICINE.

FOR RENT—Physician's office—oldest established location in Minneapolis. All modern. Four rooms including bath. Reception room shared with dentist. Address 2712 Dupont Avenue South, Minneapolis.

WANTED—Immediately, not later than July 1, physician or recent graduate for locum tenens, three months, southwestern Minnesota, about 500 population. Address D-76, MINNESOTA MEDICINE.

PHYSICIAN'S OFFICE FOR RENT—Best location Midway district, corner Thomas and Hamline. Rent $25 a month. Inquire at dentist's office.

FOR RENT—Reception room, three private offices, adapted for doctors and dentists, new modern building, Linden Hills, only $75. Other smaller suites. Yale Realty Company, McKnight Building, Minneapolis.

DENTIST WANTED—Illness of former occupant creates unusual opportunity for capable dentist; especially for one interested in extractions. Long or short term lease; nothing to sell; monthly referred work ample to meet office expenses. Apply, giving qualifications, to 612 Wesley Temple Bldg., Minneapolis.

LITERARY ASSISTANCE for the busy physician on any special subjects. Research facilities available on specialtics. Manuscripts also revised and enlarged for publication. Prompt service accorded at reasonable rates. Authors Research Bureau, 516 Fifth Ave., New York.

WANTED—Recent graduate, single, one who is interested in pediatrics and medicine. Salary $200.00. Address D-78, care MINNESOTA MEDICINE.

FOR SALE—One Kelley-Koett portable *x*-ray unit, complete, $450.00. Like new. Used slightly. Address 802 Donaldson Building, Minneapolis, Tel. Main 2904.

FOR SALE—Alpine mercury quartz lamp. Has burned only a few hours. Call Geneva 7959. 1953 Medical Arts Building, Minneapolis.

FOR SALE—New Hanovia lamp, large size, $250 cash. Address Dr. J. R. Sturre, 3402 University Ave. S. E., Minneapolis.

WANTED—Experienced technician desires temporary or part-time work with group of physicians or in hospital laboratory. Can furnish best of references. Address D-77, care MINNESOTA MEDICINE.

OFFICES FOR RENT—Excellent location for physician and dentist. Modern fireproof building. Rent very reasonable. W. C. Kregel Drugs, 2180 Marshall Avenue, Saint Paul.

WANTED—Medical man to share office, Lowry Medical Arts Building, Saint Paul. Office hours to suit. Well equipped. Telephone, Humboldt 4645.

POSITION WANTED in physician's office in or near Twin Cities by young woman physiotherapy technician. Can run urinalyses, make blood counts, also some *x*-ray. Eight years experience. Address D-65 care MINNESOTA MEDICINE.

WANTED—Position by experienced *x*-ray technician and physio-therapist, graduate of Swedish Hospital, Minneapolis. Can do general office work. Address D-75, care MINNESOTA MEDICINE.

WANTED—Physician for locum tenens, six weeks, starting July 1, Southern Minnesota town, 1,000 population. Address D-68, care MINNESOTA MEDICINE.

FOR SALE—Good general and well established practice with residence, in South Minneapolis. Leaving for West. Address D-79, c/o MINNESOTA MEDICINE.

LORD LISTER*

E. P. QUAIN, M.D.
Bismarck, North Dakota

MANY speeches have been made and books written for the purpose of calling attention to Lister's monumental addition to the structure we call modern civilization. His life, his character, and his grand gift to the human race have been described repeatedly and well. The object of this contribution, therefore, is not to add any new glory to this man, or his work. It is but a humble effort of asking the brethren to pause for a few moments in appreciative contemplation of the evangelist who first taught the world methods of overcoming the demon, SEPSIS, and who pointed out the way along which we are progressing, slowly and stumblingly, but progressing, to better and happier lives.

A medical historian, a few years ago, said that surgery is divided into two periods, first, the period before Lister, and second, the period after Lister. It will not be necessary for us to say anything about this second period or era in surgery. We have this around us all the time; it is a present-day reality through which we are plodding every day.

The period before Lister, however, was so radically different from the surgery with which we are familiar, that we might find it difficult even to recognize it as surgery. In former days only a very small number of our anatomic structures were admissible for surgical intervention. Most of the known diseases and injuries were left, for better or worse, to the tender mercies of the physician. The abdominal cavity was rarely touched by the surgeon and there was a good reason, for half or more of those who had their peritoneal cavities inspected, promptly died. In the thorax the only lesion treated surgically was empyema, which occasionally was punctured and opened before spontaneous rupture through the skin took place.

In the pre-Listerian age, major surgery was largely confined to amputations. This was a larger surgical field in the past than it is now for nearly all compound fractures required amputation. It was found that the patient had a better chance for life when the limb was amputated than he had when he retained the member and experienced fever, chills and pyemia which almost invariably followed open fractures.

The mortality records from various hospitals and surgeons about the beginning of the past century show that from 30 per cent to 50 per cent of all amputations were followed by death. In 1850 certain surgeons in Vienna and Paris were justly proud of their results after amputations, because they were able to report that only 25 per cent of their patients died. Military records made during the Napoleonic wars show that the amputation mortality among the wounded varied from 70 to 90 per cent.

The chief causes of these fatalities among postoperative patients were erysipelas, septicemia, pyemia, tetanus, and hospital gangrene. Epidemics of one or the other of these diseases occurred frequently among surgical patients in the hospitals. To our more enlightened minds, it is no wonder that these conditions prevailed when we learn that neither patient nor surgeon before operation was subjected to any other application of soap and water than that required for the sake of social propriety.

The instruments used in a major operation such as the amputation of a leg, were five or six artery forceps, a pair of scissors, and one or two long knives. These clumsy tools were probably washed or at least wiped off carefully after each operation, but had no other treatment than hon-

*Read at the Staff Meeting of the Bismarck Hospital, April 16, 1930.

ing of the knives before operation. Surgical dressings were made of discarded rags. It was the function of the Ladies' Aid Society from each hospital circle to search their wardrobes, garrets and cellars for cast-off garments and articles made of absorptive materials, tear them into suitable sizes, and bring them to the operating and dressing rooms of the hospital. In fairness it should be stated that the articles mentioned were usually if not always washed before they were brought to the hospital and used on the patient.

Many surgeons disdained the practice of certain other members of the profession of turning up their coat sleeves before operating. A few blood spots on the coat was prima facie evidence to the public that they beheld a busy surgeon. The same coat was sometimes worn until the sleeves were stiffened from dried blood clots. When the surgeon made his rounds in the hospital for the purpose of dressing his patients, he carried, hanging from a buttonhole, a wisp of ligatures—silk or linen, drawn through wax—in order to have them convenient for the control of postoperative hemorrhage. This complication was of frequent occurrence because the fifteen or twenty ligatures which had been left hanging out of the wound at the time of operation, often required traction for their removal.

The surgeon was anxious to do autopsies, then, as he is now, and he often interrupted his wound treatments and operations by doing postmortem examinations. We can readily understand, therefore, the close relation that existed between the operating table and the autopsy table.

Medical and surgical patients were not separated in the hospitals. Each patient, no matter what his ailment might be, was placed in the bed most readily available, thus mixing medical with surgical, and infectious with non-infectious patients without knowledge of the consequences. However, the surgeon had no difficulty in finding his own patients in the ward owing to the foul stench of putrefying flesh which always surrounded the surgical beds.

Surgical nursing as we understand it did not exist. The female attendants in the operating rooms and wards were handicapped, not only by ignorance, but by the old-time prudery which made it improper for a woman to expose the skin of her bared arms. Presumably, if one of the old dames of the Victorian Age could arise and take a glance into one of our modern operating rooms, she would promptly have a stroke of apoplexy and return to her grave.

The suppuration of wounds was spoken of as putrefaction and decomposition. It was believed that the underlying cause was the irritating influence of the oxygen in the air. Efforts were therefore made to exclude the air from the wounds by various forms of tight dressings, a practice which made matters worse and not better.

Surgical operations were practiced in prehistoric times and surgery occasionally had periods of remarkable development. Each period represented the existence of some one great physician, leader, teacher, and master who had exceptional powers of observation and clinical judgment, and gathered a group of disciples about him. After a generation or two the art would fall by the wayside and be forgotten again for a few hundred years, or until the arrival of another man of genius. The histories of Babylonia, Egypt, and Greece prove this statement. Even toward the end of the Eighteenth Century surgery was limited to small procedures, such as we usually include under the term of minor surgery. This was done as a rule not by the physicians of that day, but was practiced by barbers and others who had become adepts at opening boils, setting fractures, and removing foreign bodies which were easily accessible.

In the Nineteenth Century, knowledge increased so rapidly that it was necessary to differentiate its various branches. We may say that science, *i. e.*, classified knowledge, dates back to about the middle of the past century. Chemistry was early an advanced science. Among other chemical compounds developed about that time were carbolic acid, ether, and chloroform—all powerful drugs destined soon to become the most active agents in revolutionizing the healing art. Since it was thought that chemical reactions had so much to do with putrefaction in wounds, chemically trained minds became especially interested in this subject. The first reference to living microörganisms was made by Heister in 1857. He arrived at his conclusions purely by logical reasoning, for he had no means of proving the existence of living germs. He even went so far as to state: "No germs, no pus."

Semmelweiss, an obstetrician in Vienna and later in Budapest, in 1865 had noted that the

mortality of mothers after delivery was 10 per cent when delivered by physicians, but only 3 per cent when attended solely by midwives. On the theory that physicians carried living infection from one patient to another, he carried out a number of investigations and inaugurated an obstetrical practice based on scrupulous cleanliness. This was followed by unbelievably brilliant results. Unfortunately, Semmelweiss with all his genius lacked the ability to convince his confrères and the rest of the world of his golden discovery. He was downed in his tracks, figuratively speaking, by critics and unkind satirists. His great idea was not appreciated fully until after his death. Honors commemorating his work have been heaped upon his memory although but few came to him while he lived.

For some inexplicable reason, the path of medical progress has always been strewn with obstacles and obstructions placed there ignorantly and viciously by those who should have been most vitally interested in making this path smooth. Those men who have made the most far-reaching discoveries have practically all gone through agonizing periods of criticisms, jealousies, and cynical and malicious attacks from members of their own profession. One can hardly find another walk in life where opposition to progress has been similarly maintained by those who should have known better.

The same opposition met Pasteur and hampered him for years in his endeavors to convince the world of his discoveries. The proofs he adduced were at first scorned by the medical profession but accepted early by chemists and botanists. His discovery and proof that bacteria cause infection and disease was also made about the middle of the past century.

Then came Lister. Joseph Lister was born at Upton, Essex, England, April 5, 1827. His father was a merchant of education and means who, for amusement, dabbled with problems in chemistry and physics. As one result of these hobbies, he made a decided improvement in the construction of the magnifying glass. From a toy he made it into a powerful engine for the investigation of the minute structures of animal and vegetable tissues. His son Joseph was a studious boy and with his father's magnifying glass began at an early age to study the histology of animal tissues. He devised a special knife with which he could cut slices of tissue much thinner than had formerly been done. While still a small schoolboy, he experimented with frogs in an attempt to learn why and how frogs changed their color, depending on the dgree of light or darkness in which they lived. For this purpose he blinded frogs and exposed part of their bodies to sunlight while keeping other parts in complete darkness. He found that frightening the frog would cause it to change color. The sciatic nerve was cut to determine whether this nerve connection controlled the color change in the frog's foot. At the same time he watched the circulation in the frog's webbed foot with his magnifying glass and found that irritating, or, as we know now, infecting, the web would produce congestion and thrombosis. These examples are given as a few of many to show that this man was born with an insatiable thirst for knowledge through research.

He was given a thorough classical education to which was added a serviceable knowledge of French and German. He graduated in medicine from London University in 1852. While a student he had the opportunity of seeing the first operation ever made under chloroform anesthesia.

After graduation he was an assistant to Prof. Syme of Edinburgh for a time, after which he was made clinical professor in the Medical College of Glasgow, where he remained until 1869. It was here he carried out his investigations resulting in the revolutionary changes of wound treatment. From Prof. Syme he had learned the great value of cleanliness in treating wounds. When he first came to Glasgow he was horrified by the deplorable hospital conditions and the high mortality among the surgical patients. He immediately set about to make those radical improvements in wound treatments which were destined soon to become copied by surgeons all over the world.

Convinced almost from the beginning of his practice that there was something besides the oxygen in the air which brought about putrefaction in wounds, he tried by numerous experiments to learn the true cause. Among the various chemicals employed in wound treatment, he found that carbolic acid was more useful than any other drug to promote healing. At first he applied it to the wound surfaces and in the dressings in the form of a 5 per cent paste. This was at once followed by a marked improvement in

the healing process and encouraged him to carry out still more experiments. The carbolic acid treatment was first used by him in 1865. The result of the treatment was welcomed first because of the reduction of the obnoxious odor about the surgical patients and later because of the very marked improvement in mortality. When the carbolic acid paste was applied to amputated stumps, about four patients out of five recovered and, more important, wounds with compound fractures would frequently heal without suppuration under this treatment and amputation be avoided. This was a startling upset of former conditions and convictions.

While Lister was still further experimenting and using his paste, someone told him of Pasteur's discoveries. Lister called on Pasteur and together the two went over the questions of fermentation, putrefaction and infection. Lister was big enough to recognize the value of Pasteur's work and to give him full credit for his accomplishments. He promptly adopted the new discoveries for practical surgical use. Lister and Pasteur became close friends as proved by their several meetings and the volume of correspondence remaining after them.

On his return home, Lister began to use a spray of a 2.5 per cent carbolic acid solution with the idea of killing the germs floating around in the air about the surgeon and the operative field. This apparatus was at first worked by hand but later more elaborate machinery was constructed and the pump and spray were operated by steam power. The older surgeons, smug in their time-honored convictions, wasted much ink in their vain efforts to ruin this "donkey engine" as it was called, by throwing monkey wrenches of satire among its gears.

The spray was continued throughout every operation, producing a foggy atmosphere about the operating table. The surgeon's finger often became blanched and numb from the acid. The irritating effect on nostrils, eyes, and bronchi was a most distressing feature to surgeon, assistants, and patient.

There was a still further improvement, and a marked improvement, in the results of wound treatment following the introduction of the carbolic acid spray. Lister now began to do more deliberate surgery by performing operations on bones for deformities, by opening joint cavities, and even risking incisions into parts of the body which heretofore had never been entered successfully in the living.

From descriptions of Lister's antiseptic surgical technic, we gather the following: The instruments were soaked in a 5 per cent carbolic acid watery solution for one-half hour before operation; the sponges, which were of the ordinary soft elastic bathroom variety, were also soaked in a 5 per cent solution. The skin was washed with the same strength while the patient was being anesthetized with chloroform. The surgeon removed his coat and rolled up his shirt sleeves and pinned a towel across his vest. These also were radical innovations. He washed his hands in the 2.5 per cent carbolic solution. The silver, silk, and silkworm-gut sutures were all soaked in the 2.5 per cent preparation. After operation the wound was rinsed with the same solution before closing and the dressings were steeped in the same strength before being applied to the wound. Somewhat late in his experience he discovered the use of catgut for ligation purposes and adopted cheesecloth and gauze for dressings.

Lister was an original thinker and a constant searcher after more facts. He studied carefully every new reaction in his experiments and every phase of the newly discovered laws of tissue damage and tissue repair. While his surgical technic perhaps would be considered mediocre by our present standards, it should be remembered that he was the pioneer and the pathfinder dominated by the daring courage of his convictions and that he blazed roughly the trail for those who came later with finer tools and nicer methods.

Many instruments and apparatus for bacteriological and surgical uses were devised by Lister. There are instruments first produced by him which are useful even today in operations on urethra, bladder, bones, and ear drums. Bloodless operations by means of the tourniquet were practiced by Lister several years before Esmarch produced his elastic bandage. The use of rubber tubes for drainage was another of Lister's innovations.

His success grew by leaps and bounds and his reputation as a surgeon did likewise. From Glasgow he returned to Edinburgh after a few years to become professor of surgery at the University, a position he held until 1878. His assistants and students were enthusiastic followers of this new system of surgery and spread his gos-

pel wherever they went. However, the opposition to him was so strong in England that antiseptic surgery was adopted all over the European continent and in the United States before the London surgeons would acknowledge its merits. Germany became the place of greatest development for the new surgical practice. One reason for this was the high standard of medical education set early by German educators, and the other reason was that animal experimentation and the study of bacteriology advanced more rapidly in Germany than in any other country. Indeed Lister's opponents in London were able to pass an antivivisection law which hampered the study of bacteriology and kindred subjects in Great Britain for a long time. In a letter written by Lister to Queen Victoria on this subject he said, "Without experiments on lower animals I could not possibly have made the advances in surgery which I have been privileged to inaugurate."

To the German surgeons much credit must be given for adopting so early and so enthusiastically Lister's teachings and for developing during the Eighties another radical advance in the art—aseptic surgery. The stolid London surgeons were obliged to learn later the technical steps of modern aseptic surgery from Germany. This was a galling experience in view of their unkind treatment of antiseptic surgery in the first place and because of their previous statements that more cleanliness in surgery was probably necessary among the Germans because they, in comparison with the British, "are such a dirty people."

Lister continued using his "donkey engine" spray until 1887, after he had become thoroughly convinced of the superiority of the aseptic technic as an improvement over his antiseptic practice. He described with keen surprise and satisfaction his first operation with "boiled" instruments. It was nothing more than the excision of a lipoma from a shoulder but the fact that the wound healed without even a tinge of redness about the stitches was a marvelous historical event to the discerning mind of Lister. He nevertheless used "boiled" instruments only tentatively and in minor operations for some time before his final conviction caused him to bid farewell forever to the world-famed "donkey engine."

But the day of triumph came to Lister as it had come, eventually, to Pasteur. In 1887 Lister was called to London as Professor of Surgery at King's College Hospital, a position he held for six years, or until his retirement. After his fame had become established in London, he enjoyed a constant stream of visitors of surgical students and admirers from Great Britain and from many foreign countries. Among these, because of their prominence in surgery not only in their time but for all time, may be mentioned Thiersch, Volkmann, Bardeleben, Mikulicz, Trendelenburg, Kocher, Bergman, and Lucas-Championniere.

In 1878, on a visit to his friend Pasteur in Paris, Lister was given unexpectedly a public demonstration which quite overwhelmed him, for he was a man of quiet, unassuming and humble nature, quite befitting his innate greatness. At a medical congress in Amsterdam he was given a special reception and an ovation from representatives of many nations. Prof. Virchow was the speaker of the day. In 1880 Lister was made a knight and in 1903 he became a peer and therefore a member of the Upper House in Parliament. He was given numerous decorations by Royalties of his own and other countries. In 1907 on his eightieth birthday anniversary, Lister celebrations took place not only in London, where it was said that there was a solid line of messenger boys with congratulatory missives on his doorstep from sunrise to sunset, but there were special celebrations in many foreign capitals. In 1909 his eyesight and hearing began to fail but his mental powers and his keen interests in life continued until the last year of his life. He died February 10, 1912.

The British government wished to bury his body in Westminster Abbey, but owing to a clause in his will, he was buried near his birthplace. However, the funeral rites took place in the Abbey, on which solemn occasion there were gathered princes, statesmen, dignitaries, and representatives from scientific bodies from many lands.

It is hard to realize that there are many people still living who remember the pre-Listerian times. There are many doctors still living who began their practice of medicine before the term asepsis was first conceived. We have lived at the very beginning of this new era and we have enjoyed life under the magnificent heritage given us by the two benefactors of mankind—Pasteur and Lister. No greater gifts were ever given by man to man than those given us through the ge-

nius and inspiration of these two men. As a result of their lives and labors, the average span of human life has been lengthened twelve years and more, not to mention our ability to make existence much more tolerable, pleasant and profitable for ourselves and for our successors. Great movements, national, religious, scientific, and economic, were originated by many men before Pasteur and Lister, but none of those movements have rendered as far-reaching service to all men in all nations as the practical application of the knowledge of bacteria has done. Those of us who know that we would have been rotting in our graves long before now but for the simple fact that we came to life late enough to enter the post-Listerian age—we have special reasons to think with gratitude, emotion, and reverence of the names PASTEUR and LISTER.

SELECTION OF DRUGS IN HOSPITALS

The hospital should afford unusual opportunities for enhancing rational drug therapy. There particularly may products be submitted to critical inspection. As Sollmann so pointedly remarked at the recent Congress on Medical Education, the "evaluation of therapeutic remedies is not usually among the features to which hospital authorities point with just pride of achievement." The hospital drug room, which reflects directly the medicinal requests of the staff, has hardly kept pace with the modernization of other departments of the hospital. As for proprietary medicines, the shelves often remind us of what Irons aptly terms the "chain drug-soda-fountain-lunchroom." While in most medical schools the student receives good courses in pharmacology, materia medica and therapeutics and is made familiar with New and Non-official Remedies, it is unfortunately true that when the student becomes an intern in a hospital he finds not unfrequently that irrational prescriptions are written by the "chief" of a service, who has not kept pace with the trend of modern drug therapy. All too often he prescribes proprietary drugs when the same drug is obtainable under the pharmacopeial name at a much lower cost. To mitigate the evils of the prescribing of proprietaries, Irons has suggested the issuance of a hospital manual which shall contain hospital rules and a formulary. The Council on Medical Education with the coöperation of the Council on Pharmacy and Chemistry is following up the suggestion and considering the preparation of such a manual. (Jour. A. M. A., May 31, 1930, p. 1764.)

MINOR SURGERY*

FREDERICK CHRISTOPHER, M.D., F.A.C.S.
Assistant Professor of Surgery, Northwestern University Medical School,
Attending Surgeon at Evanston Hospital
Evanston, Illinois

THE writer is very grateful for the honor of an invitation to give a paper before the Great Northern Railway Surgeons Association.

Minor surgery is the surgery of low mortality; it is the surgery which requires but few assistants and which generally is done in the out-patient department, or in the office, or in the home. It is an ever-present and integral part of general practice and, in fact, of general surgery. It is probably no exaggeration to say that the group of minor surgical conditions is as numerous as any other group which the physician has to treat. Because of the fortunate propensity of the body to cure most ailments spontaneously, much inefficient work is condoned in minor surgery. There is often wider diversity of opinion as to what constitutes good minor surgery than there is in the treatment of cholecystitis or pneumonia. The subject of minor surgery is commanding an increasing amount of interest and study and some of the most careful clinical and laboratory research will be necessary to decide disputed points.

The low mortality in minor surgical conditions is no reason why these conditions should not deserve the same careful thought and standardization of treatment which is present in the graver ailments. Skillful minor surgery greatly enhances the patient's comfort and reduces his morbidity. As Kanavel says, "There is no greater field for good surgery than is presented by minor surgery."

In engineering, architecture and other professions, the elementary courses are given before, and not simultaneously with, the major courses. It is quite possible that the medical schools of the future will give compulsory courses in minor surgery and that some, at least, of the major surgery will be taught in elective courses.

The strongest plea for the teaching and practice of good minor surgery is the fact that poor minor surgery not infrequently causes the development of grave surgical conditions which could have been avoided. "Too often," says Kanavel, "minor surgery becomes major surgery through carelessness or incompetence."

We are all familiar with the occurrence of grave generalized infections from trivial breaks in the skin. The writer has seen a staphylococcus septicemia with multiple bone metastases originating from a neglected blister of the heel. The presence of a slightly infected cutaneous wound becomes important when a trauma, as a strained muscle, occurs elsewhere in the body. The bacteria will often center and propagate in the locus resistentiæ minoris. Friction blisters should be prevented if possible. If they occur they should be protected. If they seem likely to rupture they may be opened under aseptic precautions through the intact adjacent skin. Once the blister be infected, the roof should be removed and the subjacent epithelium should be treated with a mild antiseptic such as mercurochrome ointment or a 5 per cent tannic acid ointment. Children are prone to acquire abrasions over the elbows or knees. These abrasions soon become infected and healing is delayed by the constant motion of the part. Rest, and wet boric dressings are indicated and where there is a tendency to crust formation with pus beneath the crust, the latter should be removed and an antiseptic ointment or wet dressing applied.

Meticulous early care of trivial lacerations will pay big dividends in the reduction of morbidity. The first concern in the treatment of a small wound is the control of hemorrhage. Frequently a tourniquet has been applied with such tension as to occlude the veins and not the arteries. It is a common experience to see bleeding cease on the removal of such a tourniquet. Pressure and elevation of the part will stop practically any venous bleeding and most bleeding from small arteries. The vascularity of the scalp lends itself particularly to bleeding. It is practically always futile to attempt the ligation of bleeding points in the scalp. The introduction of a few sutures will control such bleeding. Spurting arteries in muscle should be ligated. To attempt

*Read before the Great Northern Railway Surgeons Association, Grand Forks, N. D., June 20, 1930.

control of muscle bleeding by suturing the skin tightly over it is poor surgical technic; a hematoma and continued bleeding will practically always result.

The hair about the wound should be shaved and the skin cleansed and treated with an antiseptic before the introduction of an antiseptic into the wound.

Recent studies of skin antiseptics have brought forward interesting results. Simmons[1] concluded that tincture of iodine was much more effective than any solution of mercurochrome for use on an unbroken skin. German[2] found acriflavine (1:800 to 1:1600) to be more efficient than gentian violet, mercurochrome and picric acid. Allen,[3] while admitting that present methods of judging antiseptics do not constitute an accurate index of their practical worth, found the halogens to be much superior to the dyes (mercurochrome and acriflavine). The most recent and most interesting study is that of Raiziss, Severac, and Moetsch,[4] who studied the sterilizing properties of various antiseptics on the infected skin. Ethyl alcohol and hexyresorcinol (S. T. 37) were found to be extremely inefficient. Two per cent acriflavine gave sterilization in 80 per cent of the cases and 7 per cent iodine in 88 per cent. Five per cent iodine was ineffective. Two per cent mercurochrome-alcohol-acetone-water solution showed only seventy-nine per cent efficiency. On the other hand, 1:2500 dilution of metaphen produced one hundred per cent sterilization. Their studies indicated that better results were obtained with metaphen in dilutions 175 and 50 times greater than those employed for iodine and mercurochrome respectively. It is not improbable that metaphen, which is chemically mercuri —4, nitro—2, cresol, will become the antiseptic of choice for minor surgical wounds. It may be used in a dilution of 1:1200 to 1:2500. The writer also uses 2 per cent aqueous solution of mercurochrome and 1:1000 acriflavine solution. Tincture of iodine is rarely used. A two per cent mercurochrome ointment in a base of 10 per cent lanolin and 90 per cent vaseline is useful for some wounds.

A wound should never be sealed with collodion; tetanus has developed following the application of collodion to a "brush burn." Punctured wounds should always be given most careful attention. They are best carbolized, and where doubt as to the source of the wound exists, tetanus antitoxin is given after first ascertaining the patient's nonsusceptibility to horse serum. A rusty nail on a fence post may be perfectly safe because no anaërobic organisms can live on it, but the nail embedded in the garden dirt is the one to fear. Moreover, a so-called "clean" nail may drive into the foot tetanus organisms which were on the skin or the outside of the shoe. Great responsibility attaches to the omission of tetanus antitoxin. Exceeding care should be taken in ascertaining if the patient has recently had horse serum or is sensitive to horse serum. Fatal anaphylactic reactions have occurred where this precaution has been omitted. Where the suspicion of sensitivity exists, a drop or two of the diluted serum should be given and the patient be carefully observed for reaction. Should a reaction occur, adrenalin is to be exhibited. In cases where it is impossible to administer tetanus antitoxin, a thorough surgical excision of the wound should be done.

Approximation of wound edges usually greatly diminishes the time required for recovery and lessens the likelihood of infection. Unquestionably, however, too many sutures are introduced in most wounds, particularly in scalp wounds. Gaping scalp wounds 1 to 1.5 inches in length will heal very quickly without any sutures whatsoever, but merely a simple bandage. In small wounds where the skin is not in motion or subject to stress, an adhesive plaster dumbbell, the narrow portion of which does not exceed 1/16 to 1/8 of an inch, is probably superior to a suture. Michel clips are also useful, but difficult to put in. Where sutures are to be placed, the anesthetizing of the skin borders with local anesthesia is greatly appreciated by the patient. For this purpose 2 per cent novocain is injected by means of a short beveled 27 gauge needle into the intact skin border. Ragged wound edges should be trimmed off and deep wounds should be drained with a small piece of rubber or a very narrow strip of selvedged gauze packing. Where the skin flap is large, counter drainage openings should be made.

Furuncles and carbuncles should *not* be traumatized by squeezing or a dull knife. Of late softening poultices, unguents, and warm boric dressings have assumed a larger rôle in the treatment of furuncles than previously. In progressive carbuncles, Carp[5] has had some success in the injection of autogenous blood at the borders of the carbuncle. Three to six intracutaneous and subcutaneous circum-injections were made under

general anesthesia. Carp believes the pain is less, the time of cure less and that the scar is minimized by this method. The administration of 3 grain capsules of bisulphate of quinine seems to have a distinctly advantageous effect in these cases. The value of tin and manganese is still in question. The studies of Besredka[6] are very hopeful in this connection. He has found that the application of dressings wet with culture filtrates has a beneficial effect on furuncles. The experiences of Rice[7] in the treatment of boils with bacteriophage are very impressive. Marked improvement was noted after treating the furuncles with dressings moistened with bacteriophage or by injecting the bacteriophage into the furuncle. When fluctuation is present, incision must be generous and must be made by a sharp knife. The tiny "medical" incisions are painful and generally ineffectual. It is preferable to insert a small gauze or rubber drain for at least the first twenty-four hours. Carbuncles which do not respond to twenty-four hours of boric fomentations should be treated by radical surgical incision with under-cutting of the flaps. Furuncles are best incised under nitrous oxide or cautious freezing with ethyl chloride. Local anethesia solution should not be injected into an infected area.

Minor fractures are often overlooked. Lipping fractures of the phalanges may be missed because of the swelling if an *x*-ray is not taken and the true lesion undiscovered until the finger heals with a bony deformity. Magnuson[8] has clearly shown in fractures of the base finger phalanx how the lumbricalis muscle exercises an extension effect on the distal fragment with the result that, unless prevented, a flexion deformity will occur at the site of the fracture. Much skill and ingenuity must be exercised in the treatment of finger fractures. Thomson[9] first described the valuable method of applying traction in finger fractures by thread passed through a hole in the nail. Numerous other methods of applying traction in finger fractures have been devised. In some cases, bandaging over a roller bandage will suffice, but *x*-ray should not be omitted after the dressing has been applied.

Fractures of the metacarpals are particularly prone to dorsal deformity because of the pull of the interosseous muscle upon the fragments. This throws the distal head of the bone into the palm of the hand, making a painful prominence. Magnuson advises treating these fractures by posterior splinting with a dorsal pad over the point of the fracture and a palmar pad over the distal head.

Fractures of the base of the fifth metatarsal are commonly mistaken for sprains. Tenderness at the point of injury and *x*-ray will make the diagnosis. Immobilization in plaster of Paris will effect the quickest cure. Similarly small linear fractures of the scaphoid of the wrist will go without proper immobilization if accurate *x*-ray be omitted. Fractures of the epicondyles of the humerus may be mistaken for a sprain of the elbow.

Falls upon the head or upon the buttocks are often the cause of painful backs which sometimes are thought to be sprains. After a few days' rest most of the symptoms disappear, only to return upon resumption of activity. In these cases there may be a compression fracture of the vertebra which is only discernible in well made lateral *x*-rays. The treatment is rest in lordosis on a Bradford frame or in a cast for six to eight weeks and the wearing of a Taylor spine brace for four to six months. Dunlop and Parker[10] have devised a useful method of decompression of compressed vertebral fractures. The reduction is effected under anesthesia by tossing the patient and, with the back in hyperextension, catching his weight at the injured area across a taut sheet folded six inches wide while strong traction is made on the body. The reduction is often accomplished merely by increasing the amount of lordosis daily for a few days by arching up the back over pillows or sandbags or by the use of a properly elevating bed.

Small deep incised wounds of the fingers may be accompanied by section of the flexor digitorum profundus tendon, which may be overlooked unless the absence of flexion of the distal phalanx is noticed. The repair of these severed tendons is made through an incision on the side of the finger, avoiding as much as possible the flexion creases. For approximation of the cut tendon ends, the reinforced stitch of Bunnell is useful. Fine chromic catgut seems preferable for suture.

The search for needles and other foreign bodies presents a dismal chapter. Unless these objects are palpable, the operation for their removal should never be undertaken without fluoroscopic control and good assistance. Prolonged dissection under direct vision is not only often

futile but may be actually injurious to the extremity.

Failure to recognize some of the more uncommon skin infections may be disastrous. In anthrax the induration surrounding the lesion and the constitutional symptoms are more severe than in ordinary pyogenic infections. The diagnosis may be confirmed by examination of the pus in cultures and smears. The treatment is not local but the administration of anti-anthrax serum. The diagnosis of actinomycosis is made by finding the pin-head sized, sulphur yellow granules in the pus and the discovery of the organism (the ray-fungus). Complete excision is of great value in the early stages. In the later stages the fistulous tracts should be freely opened and curetted. The iodides are administered. Blastomycosis is a chronic infectious disease caused by the yeast fungus. The organism is readily found in the pus which has first been moistened with a 15 per cent potassium hydroxide solution. Potassium iodide and neo-arsphenamine are of value in the treatment. Surgery is employed only occasionally.

Even a circumcision may be poorly done. Too much or too little of the foreskin may be removed or bleeding points may not be properly controlled. Moreover circumcision is doubtless performed more frequently than need be. The principal indications are marked phimosis and balanitis. Dr. Pugsley of Bayard, Nebraska, has demonstrated how a paraphimosis may often be reduced without incision by the application of finger cots.

The failure to observe the proper technic of catheterization has led to many cases of stubborn cystitis.

Cauterization of the primary lesion of syphilis prevents the early treatment which a dark field examination would indicate.

A frequent cause of failure in the treatment of paronychial infections is the incomplete removal of the finger nail. The nail base may be torn off and left behind, where it acts as a foreign body and prolongs suppuration. Many paronychias are, of course, successfully treated by simple incision of the abscess, if present, at the nail border. The dangers of inadequate treatment of felons and tendon sheath infections are well known to all of us.

Additions to our knowledge of minor surgery are being made each year. Clinical research is clearing up disputed points. A few of the newer contributions may be mentioned.

The Winograd[11] operation for ingrown toe nails is a distinct advance over the older operations. The nail and nail bed are removed but the skin edge at the lateral border of the nail is left intact.

Since Davidson[12] in 1925 announced the tannic acid treatment of burns this method of treatment has come to be recognized as one of the outstanding therapeutic contributions of the generation. The patient is placed in a heated tent and his naked skin, from which any grease has been removed, is sprayed every 15 minutes with a 5 to 10 per cent freshly prepared aqueous solution of tannic acid until the burned areas are dark brown or black and are thoroughly tanned. In extensive superficial burns the blood becomes highly concentrated. This concentration of the blood is readily demonstrated by hemoglobin estimations. Hemoglobin of 125 per cent is the danger level according to Underhill[13]; as high as 163 per cent has been reported. The active administration of fluids is energetically indicated to combat this blood concentration. At least 1 quart of fluid for every 25 pounds of body weight should be given in 24 hours.[14] Normal saline or dextrose Ringer's solution is given by infusion and hypodermoclysis and saline or tap water is given by proctoclysis. After the tanned areas are hard and dry the patient is simply left without covering in the heated tent. Should suppuration develop beneath the crusts they should be opened or partially removed and the underlying area irrigated with saline—*not* boric solution. Wide areas denuded of skin will require grafting. For this purpose Thiersch or Reverdin grafts are often suitable.

In cases of severe electric shock lumbar puncture has been found to be a valuable adjunct to artificial respiration. It should be done as early as possible.

The work of de Takats, Sicard, McPheeters and others has placed on a firm basis the obliteration of varicose veins by injection of segments with a sclerosing solution. De Takats[15] employs 5 to 10 c.c. of a solution of equal parts of a 50 per cent dextrose solution and a 30 per cent solution of sodium chloride. A segment of the vein is blocked off with the fingers while the solution is injected and for two minutes afterwards. A cotton plug is then pressed against

the injected area and held firmly in place for two days. Two injections may be given at once and the treatments twice a week. An elastic bandage is worn during the time. This treatment is often combined with ambulatory ligation of the saphenous vein. De Takats[16] says that ambulatory ligation of the saphenous vein is indicated in cases where the saphenous trunk above the knee is dilated and shows marked reflux from above. If the main reflux is from the deep communicating veins, the operation is obviously useless. The ligation reduced the number of injections below the ligation.

In perfringens antitoxin we now have a weapon against gas gangrene in cases where the development of this condition is suspected.

Since the publication of Caylor's work[17] we can no longer regard the sebaceous cyst as innocuous. In Caylor's series of 236 cases, 3.4 per cent became malignant. A percentage this high should cause us to advise the excision of all sebaceous cysts.

Fractures of the clavicle are to be treated by clavicular cross splints or figure of eight braces which are on the market. While these braces and splints are being worn, care should be taken that circulation is not impaired, that the patient give adequate exercise to his arms, and that the skin beneath the brace be kept well powdered.

The Lahey operation[18] is a distinct advance in the treatment of pilonidal sinus.

The closed treatment of empyema cavities involves minor surgical procedures of careful exactitude.

Local anesthesia has had an increasing field of usefulness in minor surgery. It can be used profitably in the revision of finger injuries where a nerve block of 2 per cent novocain is injected on each side of the base of the finger. It is also used in the removal of hemorrhoids and the excision of fissures-in-ano, and in the reduction of certain fractures. For this latter purpose the nerve block method is probably superior to infiltration.

In the treatment of many fractures the molded plaster of Paris splint has superseded circular plaster casts. These splints accurately fit any shape of the extremity and are far superior to the commercial metal splints. They are made by spreading the wet plaster bandages on a flat surface to the desired length and thickness, taking care to rub the wet bandage as it is folded over on itself. This wet splint is then carefully applied to the extremity and allowed to harden in the exact shape desired.

The writer feels that the treatment of ganglions by dispersion, that is, striking with a hard object, is superior to excision and has employed it frequently. Carp and Stout[19] found fewer recurrences after disperson than after excision. Dr. J. S. Welch of Lincoln, Nebraska, successfully treats ganglions by simply transfixing them with a fine cataract knife.

The removal of tattoo marks can be successfully accomplished by the tannic acid and silver nitrate method described by Shie.[20]

In sprained knees, painfully distended with fluid, repeated aspirations will give great relief and will facilitate recovery. The aspiration is made one inch to the outer side of the patella.

The valgus felt pad in sprains of the external lateral ligament of the ankle constitutes a very valuable addition to the treatment of that condition. These tapering pads are glued inside the shoe on the same side as the injury and take off the strain from the wrenched ligament.

The splendid results in the treatment of plantar warts by radium will highly recommend that method of treatment.

In whole blood transfusions the writer has found the Scannell three-way valve apparatus to be the most generally useful. By means of this apparatus the blood of the donor is pumped directly to the vein of the recipient. A word of warning must be said against using the same donor more than once for the same recipient. The writer has seen a serious anaphylactic reaction follow such a procedure.

The writer, in closing, wishes to urge all physicians to report in the literature all original minor surgical procedures which they have found to be of use. No matter how trivial the conditions are for which the method is recommended, all patients and doctors will welcome additions and refinements of technic.

THE ACTIVITY OF OFFICIAL PREPARATIONS OF ERGOT

Recently the conviction has grown among pharmacologists that, while undoubtedly histamine and tyramine play a part in the pharmacologic responses to ergot under laboratory conditions, they have little or nothing to do with the action of ergot as used clinically. It is generally held at present that the alkaloids are the important constituents. With the development of this belief has come naturally an insistence that preparations offered to the medical profession should contain them. In 1929 the Council on Pharmacy and Chemistry omitted from New and Non-official Remedies those preparations of ergot which, from their method of manufacture, were not likely to contain, or were not shown by proper methods of assay to contain, important amounts of alkaloids. The United States Pharmacopeia not only prescribes an efficient method of extraction in the preparation of the fluidextract, the only official preparation, but requires in addition that the preparation be assayed by a biologic method which determines the alkaloidal content. An examination of the market supply of fluidextract of ergot made in 1928 revealed only one of five to have less than the required strength. In this examination most proprietary ergot preparations were found to be altogether inactive or distinctly below the strength claimed for them. Similar results for proprietary ergot preparations, some of which are marketed in this country, have recently been reported abroad. Two investigations have recently been published that indicate that the deterioration of fluidextract of ergot does not proceed rapidly. There is no real reason why the American physician should not continue to use with confidence fluidextracts made by reputable firms in accordance with the Pharmacopeial method and shown by proper methods of assay to contain the activity required by the Pharmacopeial standard. If he uses other than official preparations, he should convince himself that the non-official preparation used actually possesses the properties characteristic of a standard ergot preparation: if it has been accepted by the Council on Pharmacy and Chemistry for New and Non-official Remedies the composition and efficiency may be depended on. (Jour. A. M. A., May 10, 1930, p. 1504.)

TUBERCULOSIS OF THE INTESTINE: ITS DIFFERENTIAL DIAGNOSIS*

J. Arnold Bargen, M.D.
Rochester, Minnesota

TUBERCULOSIS of the intestine readily divides itself into two main types, the ulcerative type and the hyperplastic or hypertrophic type. Certain writers have added a fibrous or sclerotic type.

In the first type mentioned, the gross pathologic changes are varied. The evolution of the tuberculous process may be seen, including formation of tubercles, caseation, ulceration and fibrosis. The earliest lesions usually begin in the solitary lymph follicles or Peyer's patches. The ulcers may begin as mere abrasions, and by the coalescence of numerous small lesions larger ulcers may result. In the typical ulcers there is marked infiltration of various tissue elements, everted edges, and considerable undermining. The floor of the ulcer may be formed by submucosa, muscularis, and is often covered with necrotic débris. On the serous side of the ulcers may appear groups of tubercles. In the small intestine, the ulcers are irregular, and eventually may encircle the bowel; in the colon the ulcers are transverse to the long axis and may girdle the bowel in ring-like fashion. The extent of disease, the rapidity of its progress, and the length of time the patient has had trouble, may be factors in variations of individual ulcers.

In the second type of intestinal tuberculosis mentioned, the essential changes seem to include proliferation of connective tissue, involving all layers of the bowel and extending completely around the intestine. The wall eventually becomes thick, and may present a fusiform enlargement, difficult to distinguish grossly from a new growth. The lumen may become narrowed until it is almost occluded before patients are impressed with their disability.

A third type of tuberculosis of the intestine, the so-called sclerotic or fibrous type, is probably secondary to extensive ulcerative lesions. Here there is great thickening of the wall of the bowel from connective tissue. The stenosis is usually circular and tends toward annular constriction. Such sclerotic regions may be multiple.

The pathogenesis of the intestinal lesions of tuberculosis remains a debated question. Goldberg and Smithies, who recently compiled a complete review of tuberculous enterocolitis, lean toward the view that the greatest number of cases originate primarily in the mucous membrane by direct contact with the infecting mass. This implies that tuberculosis is secondary to lesions elsewhere and this is usually the case. Others have emphasized the possibility of blood-borne infection. Still others have suggested infection through the peritoneal route. That the latter is rare is suggested by a review by Lemon of fifty cases of tuberculosis of the colon, in which there was tuberculous peritonitis in only ten.

The incidence and site of election of the lesions of intestinal tuberculosis have a significant bearing on its diagnosis. Osler stated that in 1,000 necropsies in cases of tuberculosis in hospitals in Munich, intestinal tuberculosis was present in 566. The lesions are most prevalent in the ileocecal coil; that is, in the terminal portion of the ileum and in the cecum. This applies to the ulcerative as well as to the hyperplastic forms. Why these regions of predilection, or of greater susceptibility, exist remains a debated point. Change in the flow of intestinal content, initiation of segmental mass and different haustral motion in the colon, or, as Brown has pointed out, cecal stasis, reversed peristalsis of the ascending colon, and the richness of the lymphoid structures in the ileocecal region, may all be factors in this localization of tuberculous lesions. At any rate, it is known that their incidence in the large intestine varies directly to their proximity to the cecum and inversely to their proximity to the rectum.

The significance of the presence of acid-fast bacilli in the stools often has been over-rated. Various authors have noted acid-fast bacilli in the stools of 90 per cent of the patients with pulmonary tuberculosis, of whom only 5 to 10

*From the Division of Medicine, The Mayo Clinic, Rochester, Minnesota. Read before the Trudeau Medical Society, Rochester, Minnesota, March 29, 1930, and before the Philadelphia County Medical Society, Philadelphia, May 1, 1930.

per cent had intestinal lesions. Furthermore, other acid-fast organisms, such as *Bacillus smegma* and various saprophytes, may take the acid-fast stain.

The symptoms of the well advanced cases of ulcerative or hyperplastic tuberculosis are usually

Fig. 1. Filling defect caused by pericecal lesion.

marked but rarely diagnostic. In the earlier cases they are difficult to appreciate.

In the hypertrophic type, associated pulmonary disease is often not demonstrable, although careful search of roentgenograms usually will reveal an old lesion. In such cases, ulcera tion is not a feature and the first symptoms noted are usually those of beginning or chronic obstruction. Not infrequently the patient complains first of palpable tumor, usually in the ileocecal region. Borborygmus may be present; later, nausea, colicky pains, and days of watery stools alternating with days of great difficulty in obtaining satisfactory evacuation of the bowel may occur. The roentgenogram may reveal a filling defect, not unlike that of a malignant lesion, but its large size, the general well-being of the patient, his age, and the absence of blood in the stools often will lend clues to the diagnosis. Clinically, however, accurate differentiation of a malignant lesion and of hyperplastic tuberculosis often is not possible, and surgical intervention will be necessary to establish the diagnosis. Differential diagnosis rests primarily between the hyperplastic form of tuberculosis, malignancy, actinomycosis, and the nontuberculous pyogenic type of granuloma previously reported.[2] In this granuloma there is often a history of appendicitis with perforation or of other perityphlitic inflammatory disease (Fig. 1).

The diagnosis of the ulcerative form of tuberculosis presents a much more widely diversified problem. The symptoms are often vague and varied. Pain may be periodic or constant; it may be worse after eating and may be referred to the epigastrium. Occasionally it will be severe and cramp-like, or it may be dull and constant. Frequency and severity of gas pains may increase with the advancement of the disease. Pain may be markedly relieved by movement of the bowels. Distress after eating, so-called indigestion, and hyperacidity, gas, nausea, and vomiting are frequently noted. The abdomen may have a "doughy" feel, and tenderness along the line of the colon is not uncommon. Progressive loss of weight is common. Diarrhea and constipation often appear alternately, each persisting for several days or weeks at a time. However, if lesions are extensive, diarrhea usually persists. The stools are usually profuse, thin, and watery. Grossly visible blood is usually absent.

When lesions involve the large intestine to and including the rectum, the proctoscope usually discloses a characteristic picture. The ulcers are ragged, irregular, large, with indurated edges and overhanging margins, and with patches of normal mucous membrane between the lesions. However, too often, the lesions do not involve the rectum and sigmoid portion, so that the roentgenogram offers the most important diagnostic aid.

In a paper entitled "Diseases of the large intestine"[1] appears a typical roentgenogram of an ulcerative type of tuberculosis. The most extensive deformity appears in the cecum and ascending colon. Irregular involvement of the mucosa becomes reduced as the left side of the colon is approached. There is not the immense thickening of the wall, so characteristic of chronic ulcerative colitis, and a tendency toward the maintenance of haustra persists. Writhing and rapid emptying and filling of the ileocecal coil is seen under the fluoroscope. The finding of a distant

tuberculous focus often clinches the diagnosis.

When the diagnosis rests between a regional type of chronic ulcerative colitis or amebic ulceration, the therapeutic test often will help to settle the difficulty.

The five common conditions that cause differential difficulties include amebic ulceration, chronic ulcerative colitis, diverticulitis, polyposis, and malignant disease. Except in the rare cases of bleeding, little difficulty will be encountered in distinguishing diverticulitis from other conditions, and here the roentgenogram usually will establish the diagnosis. Again, in the clear-cut case of chronic ulcerative colitis, no difficulty should be encountered. The typical proctoscopic picture, with diffuse involvement of the mucous membrane, myriads of minute ulcers, granular, easily bleeding mucous membrane, and the characteristic roentgenogram of a foreshortened, narrowed, nonhaustrated colon cannot be confused with any other form of ulceration of the colon. There is, however, a form of chronic ulcerative colitis in which parts of the large intestine other than the rectum are involved. This affords the greatest diagnostic difficulties[3] (Fig. 2). Although chronic ulcerative colitis usually begins in the rectum, it may attack all or any portion of the large intestine. Whatever segment is affected by the disease, the roentgenologic picture is essentially the same, but when a portion of the right side of the colon is affected, difficulties may arise. However, the only real similarity between this form of chronic ulcerative colitis and tuberculosis is usually that the site of involvement may be the same. In ulcerative colitis, the colon is narrowed, and there is often abrupt change from diseased to normal bowel. The absence of tuberculous foci elsewhere in the body, the length of the history, the occurrence of exacerbations and remissions, the presence of blood in the stools, and finally, the therapeutic test with the chronic ulcerative colitis serum usually help to clear the diagnosis. Occasionally, however, exploration is necessary to establish it.

Amebic ulceration may afford a real diagnostic difficulty. First, both amebiasis and intestinal tuberculosis have the cecum as their site of predilection. A patient with severe amebic ulceration may be just as sick as one with advanced intestinal tuberculosis. However, if amebiasis is present, the patient will pass large amounts of blood in the stool. Furthermore, he is less likely than the tuberculous patient to have stools at night. The tendency is rather to be free from stools at night. In cases of amebiasis the proctoscope usually will disclose characteristic, punched-out ulcers, covered by a fleck of

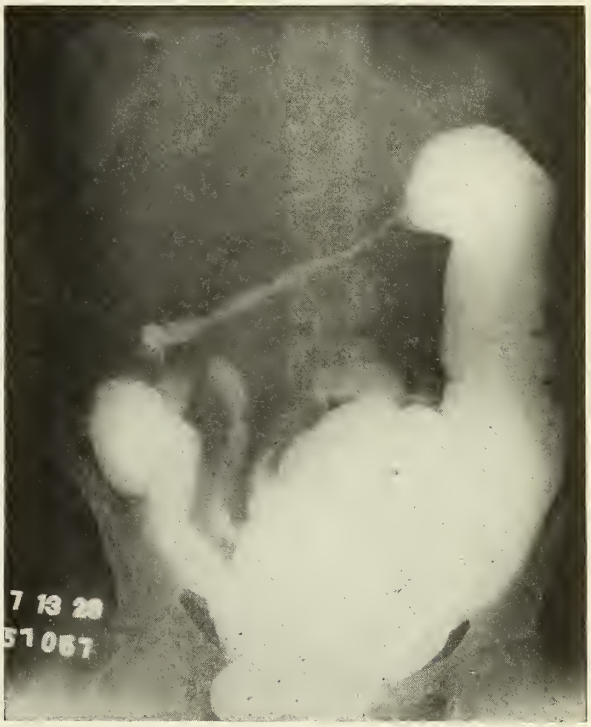

Fig. 2. The narrowed, nonhaustrated transverse colon after the barium enema.

mucus, with a hyperemic surrounding zone, and between ulcers normal mucous membrane. But in cases of advanced, extensive disease, when ulcers have coalesced to form large sloughing bases, the proctoscope alone will not suffice. The roentgenographic appearance is not often characteristic, but in some cases of amebic ulceration, positive roentgenologic diagnosis can be made. The lesions characteristically involve the right side of the colon, and present a picture resembling in some respects the involvement by chronic ulcerative colitis, but less extensive. The therapeutic test with emetine and arsenic will aid in the diagnosis. However, finding of the *Endamœba histolytica* in the stool or in scrapings from the ulcers will establish it.

The history in cases of polyposis can readily be confused with the history of a case of tuberculosis. This is particularly true because both diseases are likely to attack young persons, and because in both there is often a history of dis-

ability of long standing. Here again the proctoscope and the roentgenogram will help to clarify the diagnosis.

Malignant disease need only rarely present difficulties of diagnosis. The usual history of onset with rectal bleeding, relatively rapid progression, signs of obstruction in persons past middle life, without a demonstrable tuberculous focus, usually readily establishes the character of the trouble if malignancy is present. However, there are instances in which real difficulties arise. Cases are occasionally seen in which two lesions coexist. A case in point is briefly mentioned.

A man, aged sixty years, came to the clinic in February, 1930, with a history of pulmonary disease of fifteen years' duration, with cough, and purulent sputum, which contained large numbers of acid-fast bacilli. For a year he had experienced slight difficulty in moving the bowels, with some straining and rectal bleeding. A proctoscopic examination was negative for 24 cm. of the bowel examined. A roentgenogram of the thorax revealed evidence of active pulmonary tuberculosis; one of the colon disclosed a filling defect of the sigmoid (Fig. 3). The lesion was thought to be malignant but exploration was necessary to establish this fact.

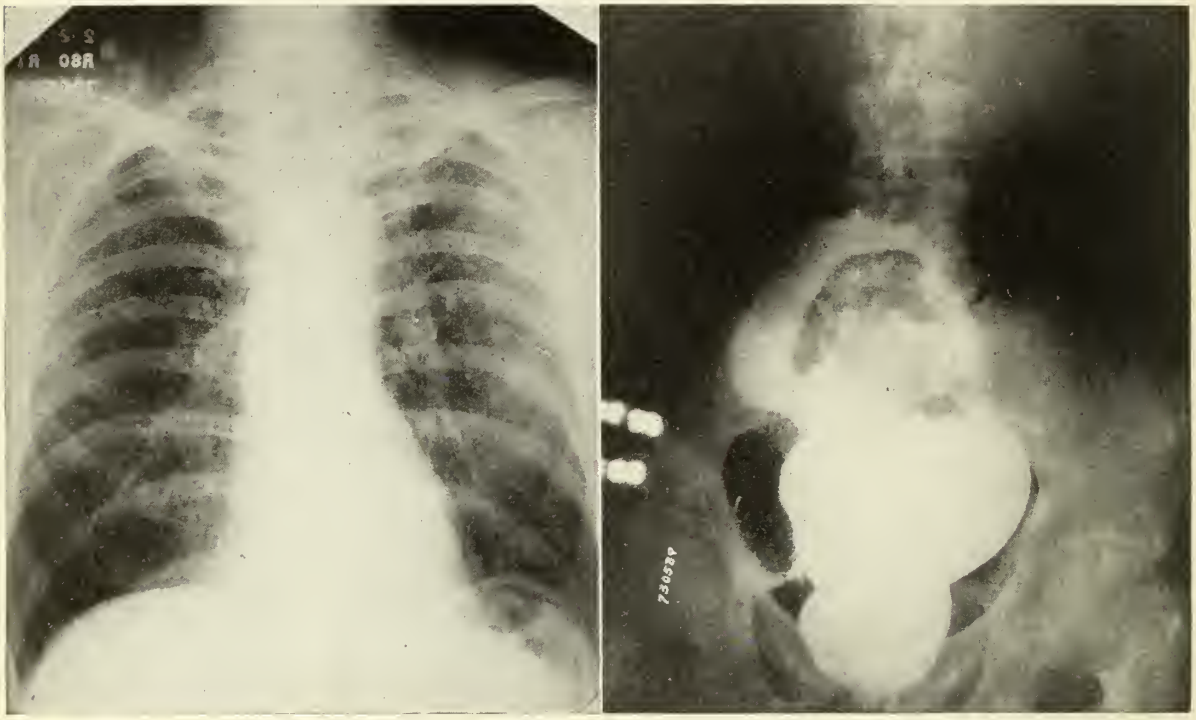

Fig. 3. *a*, The thorax of a patient with active pulmonary tuberculosis and carcinoma of the sigmoid; *b*, obstructive filling defect in the sigmoid is shown.

COMMENT AND SUMMARY

The lesions of greatest significance in making a differential diagnosis in cases of tuberculosis of the large intestine divide themselves according to the type of tuberculosis with which one is dealing. The hyperplastic type must be distinguished from malignant disease, actinomycosis, pyogenic pericecal or ligneous reaction, causing cecal deformiity, localized diverticulosis, and other benign cecal and pericecal lesions. No stress has been laid on lesions like the cholesteatoma because of their rarity, nor on renal or other intra-abdominal lesions because this study is concerned with the differentiation of lesions intrinsic in the large intestine.

The ulcerative type must be distinguished from malignant disease, diverticulitis, polyposis, amebic ulceration, and chronic ulcerative colitis.

Amebic ulceration, and the regional or migratory type of chronic ulcerative colitis, present the greatest differential difficulties.

Gross examination of the stools with the naked eye gives valuable information about the various ulcerative forms of disease of the colon. The

proctoscope and the roentgenogram are the most valuable diagnostic aids.

THE PHARMACOPEIAL CONVENTION

At the recently held Pharmacopeial Convention in Washington, the delegates with commercial interests far outnumbered those from the medical profession. For the interests that opposed medical control of therapeutics, leadership was assumed by Henry H. Rusby, the "sacred cow" of certain druggists. Rusby was testifier for the Wine of Cardui Company in its suit against the American Medical Association, a testifier for a firm against which the Post Office issued a fraud order, a testimonial producer for the Fleischmann Company, and he has been the chief supporter of Ambruster, importer of Spanish ergot, in his attacks on the Food and Drugs Department. At the previous convention an agreement was reached that the scope of the Pharmacopeia, at least so far as concerned therapeutic usefulness, be determined by the medical members of the Revision Committee and that questions of pharmaceutic necessity be determined by the pharmaceutic members. At the present convention, Torald Sollmann offered a motion to instruct the Committee on Revision to charge the medical members with the responsibility of final decisions in the selection of products of therapeutic usefulness. This motion was not adopted, instead it was decided that a two-thirds vote of the Revision Committee would finally settle the question of inclusion of any article. Since the pharmaceutical interests far outnumber the medical representation, this means that pharmacists will determine the admission of drugs to the Pharmacopeia. It is clear that the U. S. Pharmacopeia is confronted with an epoch of degeneration against which the medical and scientific members of the Revision Committee are likely to fight a losing battle. The present organization of the U. S. Pharmacopeial convention is undemocratic and unscientific. Unless some scientific plan for the revision of the Pharmacopeia is adopted, it may be necessary to advocate government control of the entire matter. (Jour. A. M. A., May 24, 1930, p. 1707.)

TUBERCULIDS*

William H. Goeckerman, M.D.
Rochester, Minnesota

TUBERCULIDS represent true tuberculous lesions of the skin. They are the result of periodic bacillemia; in the wider sense of the term, they represent an embolic obstruction of the peripheral vessels of the skin and subcutaneous tissue, the embolus or emboli arising from a deeper seated focus, usually the lymph nodes, but also the bones, intestines, and so forth. Strikingly active pulmonary tuberculosis is rarely present. Tuberculids are found in individuals with relatively high immunity quotients. Bacilli can be found in the lesions only very early; they are promptly destroyed by the defense mechanism. It is, therefore, not practical to try a search for the bacilli of tuberculosis by the usual laboratory methods, as they are not likely to be found. Individual lesions heal readily, only to be followed by new lesions periodically.

Tuberculids, therefore, represent etiologically the same but genetically quite a different lesion of the skin from tuberculous conditions of the skin such as lupus vulgaris, scrofuloderma, and tuberculosis verrucosa cutis. The latter spread by peripheral extension only, occasionally being propelled rapidly along the lymphatics. The bacilli are rather readily demonstrated in the tissues, and the evidence points to lack of specific allergy in the patient.

Tuberculids are probably of greatest significance because of their diagnostic value. In a case in which systemic symptoms are obscure, it may require their presence to reach a final diagnosis. They mean active although chronic tu-

Fig. 1. Lichen scrofulosorum.

Fig. 2. Acnitis.

*From the Section on Dermatology and Syphilology, the Mayo Clinic, Rochester, Minnesota. Read before the Minnesota Trudeau Society, Rochester, Minnesota, March 29, 1930.

berculosis. Cases are not uncommonly seen with frequent headaches, malaise, and vague pains, asthenia, lack of endurance, possibly obscure fever, or a syndrome that subjects the patient to suspicion of malingering. Patients often have a good color and they may be overweight. In such cases, diagnosis may be utterly impossible without the lesions of the skin. The symptoms of a systemic character probably represent intoxication from a deep-seated focus.

Tuberculids appear in the skin in varied morphologic forms. According to these, they have been classified; the terminology employed to designate various clinical manifestations is descriptive of their morphology.

The more common forms are called lichen scrofulosorum, papulonecrotic tuberculids, and tuberculosis cutis indurative. The genetic mechanism in all these lesions is probably the same, the morphologic manifestation being determined by the grade of immunity, the anatomic structure involved, the pattern of the individual skin reaction, and possibly other factors as yet unknown.

Lichen scrofulosorum appears as grouped,

Fig. 3. Follicli.

acuminate, follicular papules (Fig. 1). Papulonecrotic tuberculids are slightly inflammatory papules with a definite necrotic center, which can readily be picked out, leaving a crateriform de-

Fig. 4. Erythema induratum, ulcerative type.

Fig. 5. Erythema induratum, nonulcerative type.

pression. When confined to the face they are spoken of as acnitis (Fig. 2) and when confined to the fingers as folliclis (Fig. 3). Erythema induratum, both the ulcerative and nonulcerative type (Figs. 4 and 5), might be looked on as a papulonecrotic tuberclid, or as belonging to the

Fig. 6. Lupus pernio; distinction of lesions with involvement of fingers is shown.

indurative group. It has features of both and represents essentially a transitional group. One would expect such morphologic manifestations from what has been said. In the indurative group, I place the lesions formerly called the Boeck and Darier Roussy sarcoids, and true lupus pernio (Fig. 6). The Spiegler-Fendt type of sarcoid is no longer believed to be caused by the bacillus of tuberculosis but is placed with the lymphoblastomas. Sarcoids appear as brownish-gray to purplish infiltrations varying in size from a small papule as seen in the small miliary type of Boeck's sarcoid to large plaques, as seen in lupus pernio. Ususally a brownish nodule similar to that seen in lupus vulgaris may be elicited with the diascope. In lupus pernio there may be some telangiectasia. The histopathologic picture may be specific or nonspecific and may therefore be of much or of little aid in diagnosis. When the infiltrate is specific it consists of small whorls in the cutis with definite involvement of the subcuticular fat (Wucheratrophie). The individual whorls are sharply defined by connective tissue strands which in the center consist of epithelioid cells surrounded by a halo of lymphocytes associated with an occasional giant cell. Sarcoids may be closely simulated by syphilis, leprosy, the lymphoblastomas, and even certain septic processes and trichophytosis. It goes without further comment, therefore, that diagnosis must not be determined by inspection alone. A careful investigation is necessary. The indurative tuberculous lesions of the skin are fairly often associated with characteristic systemic changes. It is probable that the latter represent the same type of infiltration in other organs as that seen in the skin. Particularly striking are the distinct nodular infiltrations in the periphery of the lungs. These simulate rather closely malignant metastatic infiltrations. Infiltration about the hilum is not characteristic in this relation. Infiltration into the bones, referred to as fibrocystic changes and by various other names, and in this instance part of a syndome of tuberculosis, is a part of the picture, and search for it should always be made. In such cases there may be splenomegaly and tenderness over the splenic area. Sometimes a glandular syndrome resembling closely so-called Mikulicz's disease is seen. The patient may have a variety of other systemic and even objective complaints. Not all of these changes, however, are found in a given case. Without a proper interpretation of any possible lesions of the skin, the nature of the condition is hardly clear. Treatment resolves itself into the treatment of tuberculosis. I doubt if any local measures I have used, including roentgen rays and radium, are of any value.

ACUTE PERFORATED PEPTIC ULCER*

A REVIEW OF 53 OPERATED CASES

E. C. ROBITSHEK, M.D., F.A.C.S.
Assistant Professor of Surgery, University of Minnesota
Minneapolis

I THOUGHT it might be interesting, and possibly of value, to review some of the cases of acute perforation of gastric and duodenal ulcers which have occurred in recent years at the Minneapolis General and the University of Minnesota Hospitals, and, accordingly, have examined the available records and studied fifty-three cases. Forty-two of these are taken from the records of the Minneapolis General Hospital from the year 1920 to 1930, and eleven from the records of the University of Minnesota Hospital from the year 1924 to 1930. Only those records of the acute perforations were examined, and no notice was taken of the records of the so-called chronic or slow perforating type. In each case the diagnosis was confirmed by operation and the operation itself was undertaken by various members (one being myself) of the surgical staffs of these hospitals.

It is not within the scope of this paper to dwell with any detail upon the various phases of the subject matter, since such have been covered frequently and thoroughly by extensive clinical studies in a voluminous and abounding literature. I have, however, tried to follow up the end results in all of these cases in so far as I was able, but found it very difficult to locate any considerable percentage of the patients who belonged to a floating population, or to get the coöperation of the remainder.

Collins[1] reports finding 181 perforations out of 262 cases of duodenal ulcers examined at postmortem, and Finney[2] says that perforation is responsible for 7 per cent of deaths found at autopsy. Relative to the matter of frequency of reported cases, however, authorities vary in their statistics. Welch[1] reports 6.5 per cent; Burton,[1] 13 per cent; Deaver,[3] 20 per cent; Musser,[1] 28.1 per cent; Finney,[2] 28.1 per cent; and Fenwick,[1] 28.5 per cent. Interesting, also, is the fact that such perforations occur more frequently in some countries than in others. In a recent communication, Archibald Young,[4] Regius Professor of Surgery at the University of Glasgow, writes me: "We certainly see a very large number of cases of perforation of the stomach and duodenum in my clinic, and the same is true of the clinics of my colleagues. I think it quite certain that perforations occur here more frequently than in many other parts of the world and even in many centers of similar industrial activity to this. Many occasions have occurred where we have had to deal with two, three, or four perforations in one day, and we seldom have many receiving days without a certain number of cases of perforation. What the reason for this greater frequency of perforation is, it is difficult to say." Trout[5] also found an unusually high incidence of acute perforations of peptic ulcers among soldiers in Hawaii, and from his study concluded that peptic ulcer occurs half as frequently among white soldiers in Hawaii, and perforations four times as frequently as among enlisted men of the army, serving in the United States.

In this series of 53 cases, I find fifty-one (or 96.4 per cent) occurring in males. This is in full accord with the statistics of other observers. Brown,[6] in a study of 100 cases, found ninety-five to be among males; Dineen,[7] out of 142 patients, found 138 males; Guilleminet,[8] in forty cases, all males; and Urrutra,[9] reporting fifty-two cases, found the proportion to be 94 per cent males, as did Fermaud[10] in his series.

TABLE I
AGE OF PATIENTS

Under 20	20 to 29	30 to 39	40 to 49	50 to 59	Over 60
1	13	17	11	10	1

The youngest in this series was nineteen and the oldest sixty-six years of age, the average being thirty-seven years. This average also agrees with the statistics of other men, who claim that the largest number of cases occur in the third decade. Wise[1] claims no age, from earliest infancy to extreme old age, is spared.

*Thesis read before the Minnesota Academy of Medicine, at its meeting of April 9, 1930.

Twenty-two per cent of this series were foreign born. In their occupations there was a great deal of variety, although 32 per cent were classed as laborers.

The immediate cause of perforation is not known and, according to Moynihan,[11] not easy to discover. The solution undoubtedly lies in the discovery of the etiology of the ulcer itself. To those interested in the experimental phase of this subject, I would recommend reading the thorough article recently published by McCann.[12] It would seem logical to suppose, and as has been frequently quoted, that in the majority, the tissues at the site of the ulcer become so weakened that they are unable to continue their normal physiological function and, as a result, perforation takes place. Wilensky's[13] theory of embolic phenomena, and Sippy's[14] six factors, bearing on the cause of perforation, have been so frequently mentioned that they are undoubtedly familiar to you. Just as in other series of acute perforations of this type, so in this series, perforation followed straining, excessive drinking, occurred at work or rest, before meals, after a full or heavy meal, in the midst of sleep, and, in fact, anywhere and at any time. Two of this group had a perforation develop while each was in a hospital undergoing examinations by their physician preparatory to arriving at a diagnosis. Olson[15] is convinced that an upper respiratory tract infection, an acute outbreak of oral sepsis, a mild bacteremia, or a toxemia of any sort has a very definite relationship as a predisposing factor in an acute perforation. Colp[16] believes that a sudden physical effort and distention of the stomach are potent factors in producing a sudden perforation of a penetrating ulcer.

In this connection I should like to refer to one of the supposedly predisposing factors, namely, the use of the routine barium meal as used in fluoroscopy and *x*-ray examinations of gastrointestinal cases. Thus Eckman[17] reports five cases where an acute perforation of a peptic ulcer followed the routine use of the barium meal as ordinarily used in fluoroscopy and *x*-ray examination of these cases. More recently others have reported cases, and I myself had occasion to operate upon such a case, in a private patient, within a few hours following the completion of such an examination. Whether these facts are simply a coincidence, or whether these perforations, following the ingestion of the barium meal, follow only in ulcers of the penetrating type, or whether or not the barium meal is really a predisposing factor, I am unable to say. In any event, it has occurred and has been reported frequently enough to warrant a close observation of the patient by his physician following such an examination, until the immediate danger of an acute perforation is passed. As a matter of interest, it might be mentioned that Powers[18] reports four cases of acute perforation resulting directly from extreme trauma.

In a small number of cases, the onset of the acute perforation is the first definite indication of the presence of a peptic ulcer. This, according to Deaver[3] and others, is not the rule, however, as 90 per cent have a previous ulcer history. It must be distinctly borne in mind that the duration of the symptoms, as related by the patients upon their hospital admittance, when they are suffering acutely and are somewhat bewildered, is only more or less accurate. In this group, I find there were twelve patients who, according to their hospital records, denied ever having had any previous gastric disturbance or distress (Table II); five who had suffered only for one month or less; three who had suffered only within a period of six months; three for one year; five for two years; five for three years; one for four years; one for five years; and sixteen for over a five-year period; the longest one of whom suffered for twenty years. In two cases no time period was stated.

Thus, in this series, 75 per cent gave a history of gastric disturbances prior to the onset of the perforation. In Colp's[16] series of twenty cases, 90 per cent gave a history of previous gastric disturbance, one-third of these giving such a history of from five to twelve years' standing. In Henry's[19] series of twenty-five cases, 84 per cent had a history of gastric disturbance, "indigestion," "dyspepsia," etc., extending over months or years.

The acute symptoms were very sudden in 96 per cent of these cases, and, as previously stated, occurred with no relation either as to time, method, or place. In every instance the very sudden and acute pain, described by some as knife-like, by others as cramp-like, stabbing, violent, agonizing and so severe as to double them up, is the first, the most outstanding, the most important and severest subjective sign or symptom. Morphin is said to have little or almost

no effect in relieving the pain, which can only be likened, in its acuteness and severity, to the similar one of acute pancreatitis. In this series, the pain was referred to the epigastric region in 36 per cent, more or less vaguely without direct reference to any specific locality, to the abdomen in 58 per cent, and to the umbilical region in 7 per cent. Gibson[20] stresses referred pain, especially to some portion of the neck, chest, or shoulders, as an important secondary symptom. According to our records, in this series I did not find such radiation of pain a consistent or constant sign. It may not have been diligently sought by those responsible for the examination of the patient. In two cases pain was referred to the right shoulder; in another two, to the left; in two others, to the lower right abdominal quadrant; in one, to the back; and in one, simply to the right side of the abdomen. Nor did the records show vomiting or nausea to be constant or characteristic signs or symptoms of these perforations. They were, however, recorded in about 40 per cent of the cases, which agrees with the statistics of others, who also state that these symptoms are without much significance, in so far as a diagnosis of perforation goes.

Collapse or prostration was recorded four times in this series. Surgical shock was not recorded, nor have I myself ever seen it in these cases. Moynihan[11] denies that shock is ever present, and Brewer[21] believes the symptom greatly over-emphasized. Deaver[3] reiterates that a low blood pressure, apathy, or a change in the pulse rate are rarely seen in these cases. I agree with Olson[15] that the term is loosely used and, in reference to these cases, should be discarded. The average pulse rate of the patients in this series, as disclosed upon their hospital entrance, was 90; the temperature 98.8°; and the respirations averaged 28 per minute.

Following the sudden onset of pain, the pulse rate remains unchanged or is slightly lower, the temperature remains normal or unchanged if slightly subnormal, while the respiration becomes shallow, of the thoracic type, and increased in frequency. Such patients prefer to be quiet, motionless, with their knees flexed, while the abdomen takes on a scaphoid appearance and

becomes inflexible and rigid to a degree commonly known as "board-like." This so-called "board-like" abdominal rigidity is the chief, most characteristic and most important physical sign of a perforation. It usually is spread well over the abdomen, although it may be localized more or less definitely in the epigastric region or over the upper half of the abdomen. Hand in hand with abdominal rigidity, goes an extreme abdominal tenderness. In this series, these signs were invariably and almost constantly present. The tenderness may, however, also shift to various abdominal regions, not infrequently radiating or localizing in the lower right quadrant as in cases of acute appendicitis. Tenderness, like rigidity, is an early symptom. Obliteration of liver dullness on percussion is a sign frequently mentioned, but less frequently found. Our records report its presence in three cases. In by far the large majority, it was not mentioned nor recorded. Colp[16] believes that the obliteration of liver dullness, when present, is pathognomonic of intraperitoneal perforation, but emphasizes that it must not be confused with tympany occasioned by a distended colon, and adds that if liver dullness is percussed in the mid-axillary line this error will not occur. Gibson[20] says that the obliteration of liver dullness should not be considered positive unless a layer of air can be percussed over the liver, posteriorly.

Leukocytosis is the rule and makes its appearance early, following the onset of pain. The average count as recorded in this series was 15,000, with a correspondingly increased polymorphonuclear count. The differential leukocyte count, according to Gibson,[20] is of no assistance.

As the condition progresses, without proper treatment, a reaction sets in, during which time the patient may think and say that he feels improved. This stage is called the transitional stage, or the passing on to true peritonitis with its accompanying symptoms. If, now, a patient is seen for the first time by his physician, the diagnosis becomes more confusing, especially in so far as acute appendicitis with progressive peritonitis is concerned.

If the case is seen early, the diagnosis usually presents no difficulty. The history of the very acute onset, the extreme pain, the board-like rigidity and tenderness of the abdomen, the unchanged pulse rate with absence of shock, readily point toward the diagnosis of an acute abdomen, most likely a perforated ulcer. House surgeons and interns frequently recognize and diagnose the condition correctly before the Staff surgeon is called to see the patient. In this series, thirty-eight, or over 70 per cent, were correctly diagnosed pre-operatively. Two were diagnosed as perforated viscus, another two as acute abdomen, one as acute perforated ulcer or acute pancreatitis, two as acute perforated ulcer or acute appendicitis, and three as acute appendicitis. In five cases no pre-operative diagnosis was recorded.

Recently Vigyzao[22] mentioned the presence of subcutaneous emphysema as diagnostic of perforated ulcer. Such emphysema, he claims, is usually localized in the umbilical or cecal region. According to Wolfson and Gray,[23] this finding has been corroborated by Podlaha, who reports also emphysema of the supraclavicular spaces. Personally, I am unfamiliar with this sign and have found very little reference to it in the literature.

Where, for any reason, the case seems complicated or the diagnosis difficult, the use of fluoroscopy is recommended. Vaughan and Singer[24] refer to the early diagnosis or recognition of acute perforations of ulcers, with the *x*-ray of spontaneous pneumoperitoneum. In fifty-four of their sixty-three cases it was easily demonstrated. The free gas has been seen as early as two hours following the perforation. A small quantity is sufficient for its demonstration. The presence of free air is shown distinctly as a bright zone which shifts on change of position, being most typical when the patient is in an upright position. The sign is of great value and, when found, is considered by some as being pathognomonic. In four cases of this series, this method was used and the diagnosis confirmed at operation.

Because of the time necessarily involved in making preparations for the use of this diagnostic method in these emergency cases, and because in most cases the diagnosis can be made without it, I do not recommend the procedure as a routine measure in every case, nor would I say that the absence of the gas bubble in such an examination was a positive proof that the perforation did not exist.

At times the differential diagnosis of ruptured ulcer presents difficulties. The conditions most frequently encountered, or which must be con-

sidered, are acute perforated appendicitis, acute pancreatitis, acute cholecystitis, diaphragmatic pleurisy, intestinal obstruction, coronary thrombosis, tabetic crises, mesenteric thrombosis, and renal colic. Geier[25] has already pointed out that acute appendicitis offers the most difficult point in diagnosis and refers to Moynihan's[11] report of forty-nine cases, in eighteen of which the incision was made directly over the appendix after the diagnosis of appendicitis had been made.

Even at operation the pyloric vein cannot always be positively identified, so that differentiation between a gastric or duodenal perforation in these cases is uncertain. In this group, the large majority of the perforations occurred on the anterior surfaces of the duodenum and stomach, and within an inch or an inch and a half of the pyloric ring. They were, for the most part, of the characteristic type, being round, single, resembling a punched-out hole or opening of small size, and found usually at the bottom of the ulcer, the base of which was indurated. Adhesions, if present, were thin and of recent origin. Twenty-seven, or about 50 per cent, were recorded as duodenal, and twenty-one, or 40 per cent, as gastric. Four were classed as gastroduodenal, being found at the junction, and one, classed as jejunal, was found one inch distal to a previous gastroenterostomy. In two cases the perforation was found on the posterior wall of the stomach; in another, near the cardia; and in still another, about 3 inches from the pylorus over the fundus of the stomach. The presence and amount of free fluid was dependent upon adhesions walling off the perforation, or an active peritonitis.

I shall not attempt any description of the pathology of these perforations, nor of the pathology attendant upon them, but should like to call attention to the fact that in no less than 20 per cent of these cases the perforations are of the multiple type, and also that one and the same individual may have repeated perforations of peptic ulcers. Such a case occurred in one of this series (632, M.G.H. 1928), a male patient, who, within a period of five years, had three distinct attacks of acute ulcer perforations. The first occurred in an ulcer on the lesser curvature proximal to the pylorus; the second, post-pyloric; and the third was jejunal. Recovery in each instance, following operation, was uneventful. The case is reported in detail by Ehrlich.[26] Likewise Henry[27] reports the case of a male patient who, within a period of four years, had five distinct perforations, with recovery. Two of these were reported as gastric, two jejunal, and one not stated. Mason and Simon,[28] reviewing the literature, have been able to find records of thirty-two authentic cases of the association of two or more perforations in the same or different ulcers. Mikulicz[28] reported the first instance of this kind occurring 9 years after the first repair of a perforated gastric ulcer. The patient died and autopsy revealed a second undiscovered perforation on the posterior wall. They also state that in Vianny's[28] case there were found three perforations close together near the pylorus; and in one of Brentano's[28] cases there were four perforations, also close together on the lesser curvature. In twelve cases the sites of the perforations were symmetrically placed, one on each wall and exactly opposite each other. I mention these cases because, as the authors state, unfortunately it is rarely at operation and usually at necropsy that the diagnosis of multiple lesions has been made. Therefore, in cases of perforated gastric ulcers, both walls should be thoroughly examined at the time of the operation, a fact previously stressed by Eliott.[29]

As before mentioned, the treatment of the cases recorded in this series was given over to the various members of the surgical staffs of these hospitals. The choice of anesthetic, method of procedure pre- and post-operatively, and the steps of surgical technic were, in each instance, left entirely to the judgment of the surgeon. I find that there are recorded, in this series, twenty-three cases, or 43 per cent, in whom a simple closure of the perforation, with or without reinforcement of an omental tag or its equivalent, was performed; thirteen, or 24.5 per cent, in whom a simple closure plus a gastroenterostomy was performed; three cases in which cauterization with an actual cautery, followed by a closure of the perforation, was done; two in whom cauterization, followed by gastroenterostomy, was recorded; four in whom an excision of the ulcer with simple closure was performed; two in whom excision of the ulcer, followed by gastroenterostomy, was performed; one in whom a gastric resection was made; four who had some form of pyloroplasty, with ulcer excision; and one in whom the cautery and pyloroplasty were both used.

Gastric Resection	1																		1
Pyloroplasty with Excision of Ulcer	4																		4
Cautery and Pyloroplasty	1																		1

Just as in the surgical treatment of chronic peptic ulcers, so in the surgical treatment of acute perforation of the same, a wide divergence of opinion still exists except, of course, that cases of acute perforation are emergency surgical cases and should be, as they were in this series, operated upon as soon as practical. Pyloroplasty, in duodenal perforations, is being used with greater frequency. Gastric resection is used in some clinics, in Europe especially, but in my opinion is too formidable, shock-producing, and time-consuming an operation to be used in cases of acute perforation. Excision of gastric ulcers in these cases also is more time-consuming, and means the closing of a larger opening. We should not forget that these are emergency cases and that the time element is of the very greatest importance. In my opinion no set type of operation, unless it be simple closure of the perforation, should be used routinely in any given case. I agree with Colp,[16] who says the treatment of these cases should be the simplest, least time-consuming, and least shock-producing; and with Young,[30] who voices the same sentiment in these words: "That procedure is the best and, for the patient, the safest, which is simplest, most expeditious, most easily and conveniently applied, remembering always that the operation is being done on a patient whose margin of reserve is probably at its lowest." For these reasons he believes, and I hold to the same opinion, that the surgeon should rest content with simple invagination of the ulcer and the covering in of the vaginated area in the most effective manner which the circumstances of the case permit. That a closure of the perforation is the first and most important step in the surgical treatment of the perforation, is undebatable. Whether or not to add the operation of a gastroenterostomy, is still a much unsettled and debated point.

Those favoring gastroenterostomy in addition to simple suture of the perforated ulcer, give as their reasons:

1. That perforation alone does not cure the ulcer, in a large number of cases.
2. That the mortality rate is not affected in properly chosen cases.
3. That the danger of spreading infection is

theoretical rather than of practical importance.

4. That while the gastroenterostomy is not always successful in relieving symptoms or preventing complications, it is so in such a large number of cases that there can no longer be any doubt of its specific effect.

5. That the suture always narrows the lumen and that the gastroenterostomy safeguards against secondary perforations and subsequent stenosis.

6. That, while subsequent jejunal ulcers are a possibility to be recognized, their incidence is extremely low.

To which the objectors of the additional operation of gastroenterostomy reply:

1. That the operation of gastroenterostomy is unnecessary, the perforation itself curing the ulcer.

2. That it adds to the mortality.

3. That there is danger of spreading infection in the peritoneal cavity.

4. That the operation of gastroenterostomy is not satisfactory in 100 per cent of the cases.

5. That reperforation, hemorrhage, and stenosis are exceptional sequelæ.

6. That gastroenterostomy may be followed by jejunal ulcers.

In cases of gastric ulcer perforations, Deaver[3] still believes in adding gastroenterostomy to the closure of the perforation. Moynihan[11] uses it only when he believes that a condition, such as pyloric obstruction, demands it. This, he says, has been his custom, as it has always seemed advisable to limit the length of the operation to the minimum, and furthermore, in his opinion, cases with simple closure of the perforation have done as well or even better than those in which gastroenterostomy was added. Gibson[20] does the same, closing the perforation and adding gastroenterostomy only when obvious stenosis is present. Farr[31] argues against gastroenterostomy. Wilkensky[13] believes in simple closure during the emergency, reserving other procedures as deemed best in case labor symptoms warrant reopening the abdomen. Young[4] and his colleagues are satisfied as a rule with a simple suture or, as they call it, an invagination. Their immediate results have been very satisfactory and Young states that in many cases where the location of the perforated ulcer was such as to suggest a likelihood of recurrence of symptoms or the development of pyloric stenosis, neither occurred. In this observation he suggests that we have a valuable indication afforded by nature toward a simplification of the treatment of these cases. My own opinion, based on a comparatively small and limited experience, agrees entirely with the above surgeons, and more especially with Brenner,[32] who believes that simple closure should be performed and adds that a good practical rule is,—when in doubt, do not perform a gastroenterostomy; it can be performed later if necessary.

Drainage of the abdominal cavity is a matter of choice, or judgment and experience. One gathers from the literature and from conversation with experienced surgeons that less and less heed is given to this part of the treatment than previously. Where careful aspiration has been performed there is, in my opinion, little need for drains. Young[30] prefers to use local drainage, having, as he says, a strong conviction that by so doing he minimizes the risk of pulmonary complications.

In this series, out of thirty-one cases in which drainage was used, twenty-four improved and seven died; in eight cases where no drains were used, seven improved and one died; and in fourteen cases in which no record was made as to whether or not drainage was used, nine improved and five died.

The postoperative treatment consists mainly in placing the patient in a Fowler position, giving him fluids, including glucose, in some manner other than orally for the first 24 hours. Following this, small amounts of water may be given by mouth, increasing the amount daily, after which other fluids and proper foods may be given carefully and in gradually increased amounts; also morphin in small doses as required, and gastric lavage as necessary. Needless to say, these patients should be put on a regulated diet, be kept under observation for a period of time consistent with their symptoms and well-being, and carefully observed in a "follow-up" service for at least one year following the operation.

As to prognosis and mortality, every surgeon knows that the successful outcome depends upon early diagnosis and early surgical treatment and that these are of greater importance than the ability and skill of the operator.

As shown in Table IV, death occurred in thirteen cases of this series, representing a mor-

TABLE IV

MORTALITY

Type of Ulcer	Operative Procedure	Time Interval before Operation	Postoperative Time of Death	Post-Mortem	Use of Drains	Cause of Death
Gastric	Simple Closure	4 hours	1 day	none	not stated	Shock (probably)
Duodenal	Actual Cautery	4.5 days	6 days	yes	not stated	General Peritonitis

Gastric	Simple Closure	40 hours	2 days	no	yes	Peritonitis (probably)

tality rate of 24.5 per cent. Of these thirteen cases, five died who were operated upon within the 7-hour period, while seven others who died were operated upon within a period of time ranging from 20 hours to 10 days following the onset of the perforation. In one case the time period was not stated. In only six of these cases were postmortem examinations held. Steinbuck[33] believes that, in those dying within 3 days of the operation, death is usually due to shock; those dying in a week usually succumb to peritonitis; and those dying several weeks or months after the operation usually die of subphrenic abscess or liver abscess. He reports an average mortality of 31 per cent in a series of eighty-eight patients, while Ochsner[34] reports the mortality rate in the first 12 hours as averaging 28 per cent, and after 24 hours three times as great. Average statistics, however, of large groups reveal that when the operation is performed within the first 12 hours the mortality rate is 6 per cent; within 12 to 24 hours, 30 per cent; and after 24 hours, 80 per cent.

The value of the various surgical procedures as used in the treatment of these perforations cannot be shown or told, in so far as improvement or cure is concerned, until we learn to employ a very rigid, thorough and exhaustive follow-up system extending over a period of a year or two. As already mentioned by Brenner,[32] only by careful follow-up records extending over many months can reliable statistics be obtained as to ultimate cures. Lewisohn[35] has most diligently and thoroughly followed up his cases of acute perforations and says that while he feels that radiology ought to be freely employed in follow-up clinics on these cases, yet, in the presence of a previous operation on the pylorus or duodenum, a deformed bulb is not a definite indication of the presence of a recurrent ulcer; that, on the other hand, marked tenderness of this region during the fluoroscopic examination, niches and retention, indicate that the patient still suffers from an inflammatory process at or near the pylorus.

With the excellent and generous assistance of the social service and out-patient departments of these hospitals where the patients were treated, I have attempted by letters, questionnaires, and interviews, to reach these patients and persuade

TABLE V.

END-RESULTS

No.	Type of Ulcer	Year of Operation	Operative Procedure	Result	Symptoms	X-ray	Year of X-ray	X-ray Diagnosis
23	Gastric	1926	Simple Closure	Complete Recovery	None	None	.....

them to appear at the hospital for physical and *x*-ray examination, to learn their present condition in so far as it related to the presence or absence of a peptic ulcer. The questionnaire, copied from one used by Young and his colleagues, is as follows:

1. How long have you been sick or ill before you came to the hospital?
2. How have you been feeling since that time?
3. Have you made a complete recovery?
4. Do you have now, or have you had at any time, any of your former or previous symptoms, pains, distress, stomach trouble or indigestion?
5. Do you take food well now?
6. Do you have any pain after eating now?
7. Do you have any trouble with the bowels, either constipation or looseness?
8. Have you gained or lost weight since the operation?
9. Have you any sickness, distress, vomiting, nausea, throwing-up your food, pain with meals, bleeding from the mouth, or hemorrhages?
10. Have you any bleeding by bowel, from the rectum, or black tar-like stools?

Because many patients of this series were transients who moved away from the city and

could not be located, and because others had failed to answer letters and questionnaires or return to the hospital for physical and *x*-ray examinations, I was able to trace only seventeen of the forty surviving members, a number too small to be of any great value in favoring any definite conclusions. Of these, one died of general paralysis two years after his operation. Of the remaining sixteen, I found seven who had duodenal ulcer perforation and three with gastric ulcer perforation who considered themselves free from symptoms and completely cured, and six duodenal ulcer perforation cases with recurrent symptoms and incomplete cures. Of the latter six, four had gastroenterostomy, one a simple closure, and one an excision of the ulcer area with a Horsley operation. Of the ten who had complete cures, three had a simple closure operation, three had a gastroenterostomy, two had excision of the ulcer—one followed by gastroenterostomy and the other by closure, one had a Polya anastomosis operation, and one a cauterization operation.

Lewisohn,[35] who has followed up thirty-three cases of perforated gastroduodenal ulcers with most thorough investigations, concludes that "conservative measures heretofore applied in acute perforations of gastroduodenal ulcers fail to effect a permanent cure in a large percentage of cases." He thinks it might be advisable to attempt a radical cure (subtotal gastrectomy) in cases which come to operation very early and where the infection has not spread beyond the immediate neighborhood of the ulcer.

A study of these fifty-three cases leads to the following conclusions:

1. Early diagnosis and early surgical treatment result in the lowest mortality.

2. Simple suture suffices, with a minimum of risk, in these acute emergency cases.

3. Patients should be kept on a restricted diet and under close observation at follow-up clinics for at least one year. If marked symptoms still exist at that time they should be subjected to a second operation as deemed most advisable by the surgeon.

My thanks are due to the superintendents of the Minneapolis General and Minnesota University Hospitals, as well as to the chiefs of the surgical divisions, the staff members and the social service workers of these hospitals, for their assistance and permission to review and study these cases.

SERENIUM

According to advertising material sent by E. R. Squibb & Sons to physicians, "Serenium" is " . . . the result of a search for a compound that would be superior to other chemotherapeutic agents in the treatment of genito-urinary infections . . . synthesized by Dr. Ivan I. Ostromislensky . . ." The circular recites various more or less ideal qualities to be desired in such a preparation, leaving the impression that "Serenium" possesses these. For the claims made for the product the evidence is slight indeed. Squibb & Sons have apparently abandoned, so far as this preparation is concerned, the conservatism that has characterized the house for nearly three quarters of a century. The advertising does not present any real proof of merit. Squibb & Sons have not requested an examination of the product by the Council on Pharmacy and Chemistry. (Jour. A. M. A., May 31, 1930, p. 1783.)

THE ACTION OF VITAMIN D

Viosterol administered to animals over long periods in doses 100 times greater than the minimum antirachitic level showed no effect on general appearance, growth, reproduction, or resistance to respiratory infections. An overdosage ten times greater was just perceptibly harmful, 4,000 times overdosage definitely injurious, and 40,000 times overdosage strongly toxic. Apparently the harmfulness may be modified by other dietary factors. Recent studies have made it clearer that Vitamin D controls calcification of the skeleton by dissolution and deposition of the bone salts. The mineral content of the bones is the resultant of these two actions. Calcium and phosphorus must be present in the diet in sufficient amounts and in appropriate relationship to each other before proper bone growth or calcification can occur. No amount of vitamin can correct an absolute lack of bone-building salts. (Jour. A. M. A., May 10, 1930, p. 1505.)

A CASE OF TETANY AND EDEMA IN THE NEW BORN*

W. Ray Shannon, M.D.,
St. Paul

TETANY in the new-born infant has not been frequently reported. It is the purpose of this paper to report such a case together with the autopsy findings and in so doing to support the contentions of certain writers that this condition is perhaps not so uncommon as has been thought to be the case.

Kehrer[1] in 1913 reported a series of six cases of tetany in the new-born. The essential characteristics of the picture were spastic contractures of the upper and lower extremeties, positive Chvostek and Trousseau phenomena, hyperactive reflexes with frequent ankle clonus, irregular tonic and clonic contractions of the musculature of the face and extremeties and, in one case, increased electrical excitability. The muscular spasms were not constant. The slightest disturbance would precipitate them. Cyanosis, especially about the face, was noted in several cases. The hand sometimes assumed a fist position in the spasms while at other times the fingers were extended in typical carpal spasm. The position of the feet was that of the classical pedal spasm. A hard edema was present over the trunk and extremeties in two cases. These two were included among the five infants who were afforded prompt relief upon the administration of calcium. One of the series died but it is not indicated in the text whether or not calcium was administered before death.

Von Reuss[2] does not concur with this author in the diagnosis of tetany of the new born. Grulee[3] also, as most of the other writers on the subject,[4] has taken a similar position. Shannon[5] on the other hand, agrees with Kehrer and feels that tetany is not extremely uncommon during the new-born period. He has reported several cases in which this group of symptoms occurred in conjunction with a generalized edema of the new-born, both the edema and the nervous manifestations yielding rapidly to therapy directed at the calcium deficiency. In further support of this contention the following case is presented.

The patient, a baby boy, was born October 4, 1929, by normal delivery. On October 6 he developed symptoms which proved to be due to a low grade peritonitis of indeterminate origin. After operation on October 7, he improved rapidly so that by the evening of October 9 he looked very well indeed. During this time he had been receiving some breast milk and a complementary feeding of half milk and half water plus five per cent dextri-maltose. Five hundred and eighty c.c. of .9 per cent NaCL solution had been given by hypodermoclysis from October 6 to 9 inclusive.

Late on the afternoon of October 9, moderate generalized edema was noted. This was much more marked by the morning of October 10. At this time definite nervous symptoms were noted in the patient. They consisted of periodic spasmodic strabismus, spasm of the circumoral muscles giving rise to the pursing or pouting position of the lips, hyperactive reflexes and a condition of general rigidity affecting muscles of the trunk as well as those of the extremeties. The position of the feet was that of extension of the foot at the ankle with plantar flexion of the toes. The hands for the most part were clenched tightly in the fist position but at times would assume the obstetrical position. There was a tendency to a flexion of thighs on the abdomen and of the knees on the thighs. The arms were flexed at the elbows. The infant cried out frequently and the least disturbance would give rise to a sudden extension of all four extremities with gradual return to the flexed position described. The Chvostek was definitely positive.

Parathyroid extract, 0.25 c.c., was administered at 11:45 a. m. by hypodermic injection. Ten grains of calcium gluconate in water was ordered at frequent intervals, a total of 55 grains being given throughout the rest of the day. At 5 p. m. the edema and the nervous signs were more marked. At 9:30 p. m. the muscular rigidity had somewhat relaxed and there was a perceptible decrease in the edema. The Chvostek was slightly positive. Slight pursing of the lips still occurred as did also the strabismus, at intervals. The hands were rather stiff. Another 0.25 c.c. of parathyroid extract was given at 10:00 p. m. During this time the patient had nursed and taken the complementary feeding well. His general condition was excellent.

By the morning of October 11, a loss of four ounces in weight had occurred accompanying a marked loss of edema. The patient was very placid, lying in the crib quietly without crying. He took his feedings well. The Chvostek was absent as were also the general rigidity, spasms of the hands and feet, and pursing of the lips. Occasional spasmodic strabismus still oc-

*From the Children's Hospital, Saint Paul. Read before the Minnesota Pathological Society, April 22, 1930.

curred. A total of 50 gr. of calcium gluconate was given throughout the day.

By October 12, a loss of two more ounces in weight had occurred with a further reduction in the edema. The Chvostek was still absent and spasmodic strabismus no longer noted. However, the infant was slightly more irritable and the knee jerks were definitely increased. The general condition was excellent in spite of the fact that the abdominal skin wound, which had broken open the night before, was wide open and showed no signs of healing. Feedings were taken well. Slight regurgitation was noted. A total of 70 gr. of calcium gluconate was given throughout the day and 0.25 c.c. of parathyroid extract.

By October 13, the edema had almost entirely disappeared. However, the nervous symptoms were slightly increased in that the Chvostek was just demonstrable. A total of 60 grains of calcium gluconate were administered throughout the day. The infant continued to nurse well and appeared in splendid condition.

By the evening of October 14, the edema was defiitely increased. Marked increase in nervous symptoms had occurred. The Chvostek was marked. In addition a definite masseter jerk and a jerking of the head toward the side from which the impulse came occurred with each tapping of the cheek. This latter was due to sudden contraction of the neck muscles. The patient was irritable, crying much more than the preceding day. General rigidity was increased and the arms and legs, hands and feet were spastic. The hands were held in a tightly clenched position. The general condition of the patient was very good, although the abdomen was slightly distended and the infant rather constipated, for which enemas were employed. Feedings were well taken, and no vomiting occurred. A total of 60 gr. of calcium gluconate was given throughout the day. Parathyroid extract was purposely withheld.

The next morning (October 15) the edema was slightly increased but very marked increase in nervous symptoms had occurred. The Chvostek, masseter and neck jerks were very marked. General rigidity and spasticity of trunk and extremeties was extreme. Carpopedal spasm was present. Spasmodic strabismus was very marked. The patient vomited some at every feeding. Rather obstinate constipation and some distension continued, necessitating frequent enemas. The blood calcium was found to be 9.0 mg. per 100 c.c. Calcium gluconate was discontinued after 30 gr. had

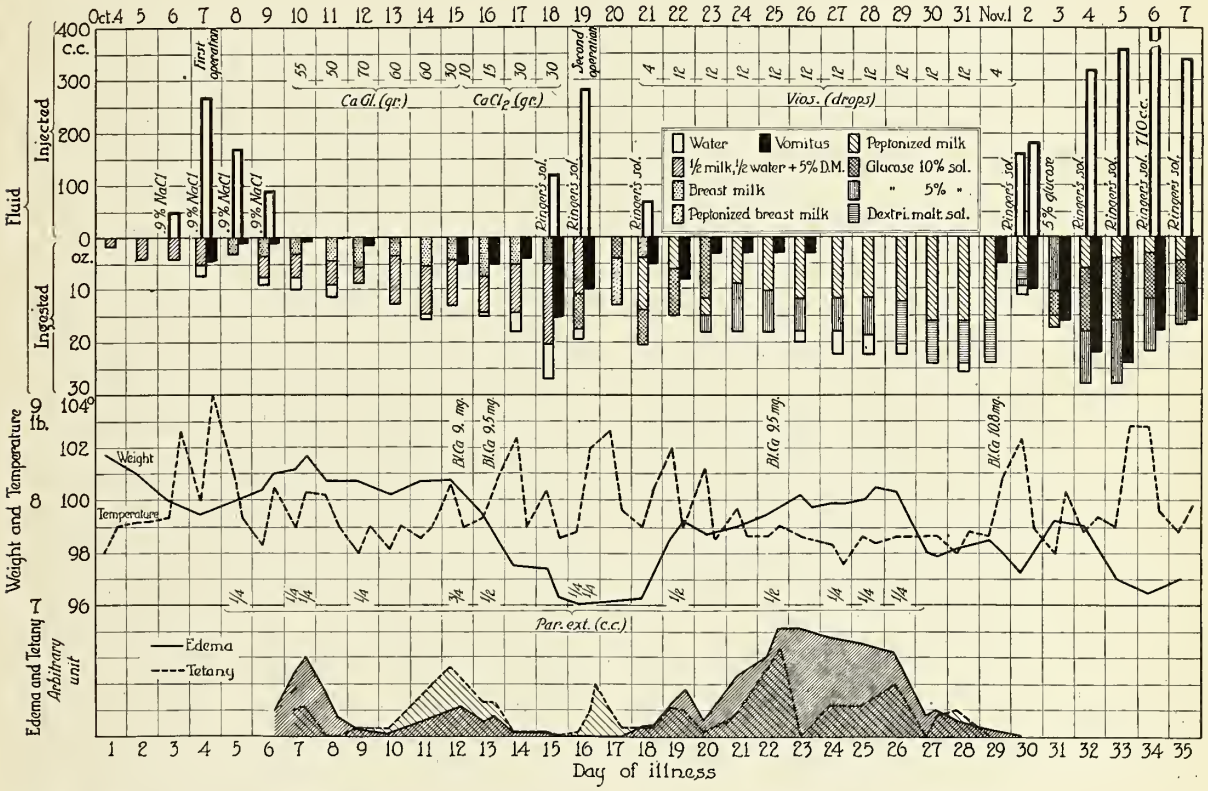

Fig. 1. The chart is for the most part self explanatory, with the exception of the lower tier of shaded areas and certain of the abbreviations. The former constitute a graphic representation of the degree of tetany and edema noted clinically at the various periods of observation. The unit is necessarily arbitrary but the method affords a striking and sufficiently accurate means of picturing what was actually observed. In the upper diagram some of the fluid represented as ingested was really introduced per rectum and similarly some of that recorded as vomited was lost through failure to retain rectal instillations and through intestinal fistulas. Of the abbreviations Ca.Gl. stands for Calcium gluconate, Vios. for viosterol and par. ext. for parathyroid extract (Collip).

been given and calcium chloride in five grain doses substituted. Three-quarters c.c. of parathyroid extract was administered at 4:20 p. m.

On the morning of October 16, there had been a loss of five ounces in weight with a definite loss in edema. A marked decrease in nervous symptoms had also occurred, the Chvostek being barely discernable and general rigidity and irritability less pronounced. However, spasmodic strabismus was still prominent and reflexes were hyperactive. In general appearance the patient seemed to be comfortable and in good condition. The skin wound was still open, however. Vomiting had occurred frequently during the night after the calcium chloride was given. Blood calcium was found to be 9.5 mg. per 100 c.c. By evening there was an increase in the edema. One half c.c. of parathyroid extract was therefore administered at 8:30 p. m. Calcium chloride had been discontinued since noon because of the vomiting.

By the morning of October 17, a further loss of 7.5 ounces in weight had occurred, with almost complete disappearance of the edema. There remained only an edema of moderate degree over the scrotum. Nervous irritability had entirely disappeared. The Chvostek was absent. Vomiting was much less, the patient having nursed and retained a feeding of 2.5 ounces at a morning feeding. The abdominal wound seemed to be healing to some extent. Thirty gr. of calcium chloride were given during the day.

At the morning visit of October 18, it was found that an abdominal fistula had occurred, apparently involving the upper portion of the small intestine. Considerable loss of ingested fluid occurred through this opening although no vomiting at all occurred. A loss of 1 ounce more had occurred since the preceding day. With it all trace of edema had disappeared. All nervous symptoms of tetany were also absent. The patient took fluids eagerly and nursed vigorously at the breast. One hundred twenty c.c. of Ringer's solution were given by hypodermoclysis.

On the morning of October 19, all signs of edema and tetany were absent. The patient appeared vigorous and active. Ingested fluid and food was coming through the fistulous opening so quickly that it seemed advisable to attempt to close it. This was done. Large amounts of Ringer's solution were given subcutaneously both before and after the operation. Late in the afternoon the general appearance of the patient was good. However, a beginning general rigidity was noted and the Chvostek was positive. No edema was noted. Parathyroid extract (0.25 c.c.) was given. This was repeated at 11:00 p. m. when all nervous symptoms seemed to have increased in severity. Edema was still absent.

The following morning (October 20) the Chvostek was still slightly positive but general rigidity was less marked. Spasmodic strabismus was still present. The Chvostek was slightly demonstrable. By evening the Chvostek was absent and there was no strabismus. Reflexes, however, were rather hyperactive. The calcium had been discontinued since the operation and was never reordered.

On October 21, a slight return of edema was noted in the morning. Nervous symptoms were about the same as the night before. The general condition of the patient was very satisfactory. Viosterol, 2 gtt. per feeding, was ordered on this day. During the night the wound broke open again and discharged a small amount of intestinal contents.

On the morning of the twenty-second the patient was definitely more irritable. He jumped at sudden disturbances, extremeties were rigid, and spacticity of the hands and feet was observed. The Chvostek was positive. Parathyroid extract (0.5 c.c.) was given at 10:30 a. m. The edema noted the day before had increased markedly and there had been a corresponding increase in weight of 10 oz. Hypodermoclysis of Ringer's solution had been given during the night and the morning. By evening the edema had increased perceptibly in spite of the parathyroid extract but there was a slight decrease in nervous irritability. The general appearance of the patient at this time was surprisingly good. Slight drainage of intestinal contents into the wound was noted. Moderate vomiting occurred. Temperature had been somewhat elevated during the day.

On the morning of October 23, a very definite decrease in edema had occurred. The Chvostek had disappeared and an accompanying loss of other nervous symptoms was noted. Vomiting was relatively slight. Distension occurred during the day and was relieved by enema.

By the morning of the twenty-fourth a marked increase in the edema had occurred. The Chvostek was present to a slight degree. Throughout the day both edema and nervous irritability increased. October 25 the Chvostek, neck and masseter jerks were very definite, the patient was extremely irritable and spastic, cried a great deal and the edema had increased. The abdominal fistula seemed to be closing, a very small amount of intestinal content coming through on the dressings. Blood calcium at this time was found to be 9.5 mg., so 0.5 c.c. of parathyroid extract was given hypodermically, at 2:45 p. m. Edema and nervous symptoms continued to increase throughout the day.

October 26 the edema was greater than on the morning of the twenty-fifth but less than on the evening of that date. Marked edema was present over the scalp, trunk, scrotum and extremeties. That over the thighs, to a less extent over the calves and upper arms, was a hard edema such as has been described in scleredema. This same condition had been noted before in this case and had entirely disappeared under therapy. While such marked edema was still present a very definite decrease in nervous symptoms had occurred. The Chvostek was negative, the patient was placid and not at all irritable, there was no spasticity and reflexes were not hyperactive. The patient was perspiring very freely and, as always when edema was disappearing, was urinating very freely. Constipation was increasing, so petrolagar was ordered. By evening the edema had slightly decreased.

October 27 the edema seemed slightly less but was still very definite, especially the hard edema above noted. Nervous symptoms were increasing in that the

patient was crying and jumpy, and the Chvostek was positive. Reflexes were hyperactive. The patient was, however, eating well and not throwing up. Very slight intestinal drainage was coming through the fistula. Parathyroid extract, 0.25 c.c., was again given on this date.

October 28 the Chvostek was still positive and the edema was about the same. Another 0.25 c.c. of parathyroid extract was administered. On the twenty-ninth slight decrease in edema was noted but otherwise the picture was essentially the same. During this period the infant was eating well, not throwing up and appeared remarkably well except that an obstinate constipation was present, requiring enemas. Again 0.25 c.c. parathyroid extract was given.

By the next day a tremendous change had taken place. The edema had melted away as shown by the loss of 9.5 ounces in weight. All swelling had left the face and scalp. Slight piting could still be demonstrated over the backs of the hands and dorsum of the feet. The scrotum was still definitely edematous. The hard edema had for the most part left the thighs and remained only in small spots of induration. Together with this loss of subcutaneous fluid there had occurred an almost complete loss of the nervous symptoms of tetany. The Chvostek was negative, the neck and masseter jerks had disappeared, the patient lay quietly in the crib and was not irritable, or jumpy and he did not cry. Reflexes were present but not hyperactive. He took his feedings greedily without vomiting. These were increased to four ounces per feeding in order to satisfy him. As was expected the patient was urinating freely. During the evening and the next day there was a slight increase in nervous symptoms and possibly in the edema, both of which receded rapidly so that both disappeared permanently by November 2, without further treatment than the administration of 12 gtt. of viosterol daily.

All day October 31 the patient continued to appear very well. He took his feedings well without vomiting except a very small amount of spilling over after taking his bottle. Practically no drainage occurred from the fistula. He suddenly developed the picture of an acute complete obstruction on the morning of November 1. Tetany or edema did not return. The blood calcium was 10.8 mg. per 100 c.c.

From this time on it was very evident that the patient was fatally ill from the obstructive condition. Measures employed included tube feeding, subcutaneous fluids, transfusions, and finally a third operation without success. The patient finally died, November 11.

At postmortem performed by Dr. K. Ikeda, a generalized plastic peritonitis was found with the intestines matted together in such a manner as to make it difficult to separate them even at autopsy. There were numerous pockets of pus throughout the mass. Spinal fluid calcium was found to be 5.4 mg. Very careful search was made for the parathyroid glands. Only one such structure was found and this was very small, about the size of a pin head. By serial sections two more parathyroids were found. No microscopic abnormality could be detected.

SUMMARY OF CLINICAL FINDINGS

The case then is that of a new-born infant who during a period of illness lasting slightly more than a month presented a group of symptoms which have previously been assumed by at least two writers as indicating a condition of tetany due to deficiency in the calcium metabolism. The underlying illness was a low grade peritonitis which eventually caused death. The symptoms that occurred throughout this illness consisted of certain nervous signs and a generalized edema. These symptoms were amenable to parathyroid and calcium treatment at first temporarily and finally permanently when viosterol was added.

The nervous symptoms were of several types. The first was a general nervous irritability the essential characteristics of which were sleeplessness, restlessness, frequent crying, and a constant primed state, like a coiled spring, which caused all types of slight disturbances to precipitate very much exaggerated responses. Secondly, there were the motor symptoms. These consisted of a general muscular hypertonia of the entire skeletal musculature, and of tonic spasms of the muscles of the arms and hands, legs and feet, and face and eyes. The spasms of muscles of the arms and hands gave rise to a rigid flexion of the forearms at the elbows, which in turn were pressed firmly against the chest, with most frequently a tight clenching of the hands into a fist position. At times the hands were flexed at the wrists with the extended fingers flexed on the palms at the carpophalangeal joints and the thumbs drawn beneath the fingers. The spasms of the legs and foot muscles held the thigh for the most part flexed on the abdomen with the legs tightly flexed at the knees and feet extended at the ankles. Toes were drawn down into extreme plantar flexion. At times the legs were rigidly extended and it was not unusual for the toes to be extended and spread. The positions described as usual for the legs and arms were occasionally interrupted, especially with the occurrence of sudden disturbances, by sudden spastic extension of all four extremeties with a slow return to the former position. Spasm of the facial muscles showed itself in occasional grimaces but for the most part by a pursing or pouting position of the lips; that of the eyes by a spasmodic strabismus affecting now one eye and then the other. Clonic spasms were not present in this case.

The third type of nervous irritability was shown by the presence of a markedly positive Chvostek. Trousseau's phenomenon could not be demonstrated with certainty since such spasm as it produces was constantly present. Unfortunately Erb's phenomenon could not be shown because proper apparatus was not available. Still another nervous symptom was noted in the extremely exaggerated reflexes. This was emphasized by the following phenomenon. Each time an attempt was made to elicit a Chvostek, not only did the facial muscles contract but also the masseter muscles suddenly closed the jaw and the neck muscles causing the head to jerk toward the side from which the impulse came.

The edema was mainly a simple edema effecting, in its most marked phases, all of the subcutaneous tissues such as has previously been described.[5] At times it was more prominent in the dependent parts giving rise to a lop-sided appearance of the various regions. On the other hand certain locations were more subject to its occurrence than others. It occurred earliest and persisted longest in the scrotum, dorsum of the feet and backs of the hands. While for the most part it was a simple pitting edema, on two occasions during the most extreme phases there occurred over the thighs especially and to a less extent over the legs and upper arms a hard edema similar to that described as occurring in scleredema. This pitted deeply but only under firm and continued pressure. As this edema receded under treatment it remained longer in small lumpy areas not in dependent areas.

SUMMARY OF THERAPY

Therapy in this case was of two types; that against the underlying peritonitis and the obstruction resulting therefrom, and that to combat the symptoms of calcium deficiency. The former consisted of breast feeding as long as possible and then the choice of artificial feedings that were thought to be best adapted to the needs of the infant, gastric lavage and gavage when necessary, rectal installations of normal saline and glucose, subcutaneous injections of normal saline and Ringers solution, petrolagar and enemata as obstruction developed, and finally blood transfusions. Reoperations were performed on two occasions by Dr. Harry Zimmermann in the effort to close fistulas and relieve obstruction.

Treatment of the calcium deficiency consisted of the administration of calcium gluconate and later calcium chloride by mouth, the administration of parathyroid extract (Collip) by hypodermic injections according to the clinical condition and calcium determinations, and finally the administration of viosterol as a reinforcement measure.

DISCUSSION

There are several features in this case which deserve special mention. The Chvostek has been almost universally denied any significant relationship to tetany at this age period. Such has not been the case in this or any other instance of new-born tetany that I have seen. The Chvostek appeared and disappeared along with the other nervous symptoms, very evidently dependent upon the same underlying factors. The fact that it is so very common in the new-born period may very well indicate that temporary failure of the calcium metabolism is indeed very common at this time.

The hard edema which resembles that occurring in scleredema was noted also in Kehrer's report. During development it was not noticed to be any different from that which was present over the rest of the body except that it gradually assumed the hard character described. During recession, however, a marked difference was noted in that instead of a gradual uniform disappearance it remained for a longer time in irregularly distributed areas giving rise to a lumpy character of the skin. These remaining areas were not confined to the dependent parts.

The extreme sweating noted at times of active symptoms is commonly found in tetany. Marked diuresis was present during periods of improvement in the edema, as would be expected. This effect on edema in certain cases of nephrosis, nephritis, and cardiac failure has been attributed to the effect of parathyroid extract by Meakins,[6] Reitzel and Stone,[7] McCann,[8] and others.[9] Hartley has observed similar effects on the edemas of pregnancy.[10] I also have reported it in the edema accompanying tetany of the new-born.[5] In this condition it would seem to be due to the increase in blood calcium since it also may occur under calcium therapy alone.[11]

Because of the fear that the first occurrence of edema might have been due to the large amounts of sodium chloride that had been injected under the skin, Ringer's solution was used for further hypodermoclysis. This did not alter the occurrence of edemas as long as the nervous symptoms of tetany persisted. However during the last few days of the infants life when all tetanic manifestations had at last been controlled, very much larger quantities of Ringer's solution were injected without the production of edema. Attention should be called to the fact that permanent disappearance of the tetany occurred only after viosterol was employed.

Blood calcium values deserve special consideration. Unfortunately this determination was not made before treatment was begun. However, in spite of very vigorous treatment preceding the first determination the figure was only 9.00 mg. per 100 c.c. This value alone would perhaps have very little significance but when one considers the relatively tremendous amount of treatment that had been previously employed, it becomes significant indeed. A total of 325 grains of calcium gluconate had been given during the five days preceding. Like dosage to an adult would have been about 53 grams per day. The 0.75 c.c. of parathormone would have been the equivalent of between 13 and 14 c.c. in an adult. That in spite of such vigorous treatment the blood calcium should not be up to normal[16] would strongly support the contention that some deficiency in calcium metabolism was present. The difficulties encountered in establishing a premanent disappearance of the nervous symptoms and the edema is worthy of special mention. Calcium feeding in combination with parathyroid extract produced several periods of temporary improvement. This could not be maintained on calcium alone as shown by the fact that shortly after the parathyroid was stopped the symptoms returned.

Finally calcium was discontinued entirely and viosterol was added in the amount of 12 gtt. daily. The last flare-up occurred shortly after this was started and was controlled by parathyroid extract in addition to the viosterol. The blood calcium at the end of this exacerbation was 10.8 mg. and neither nervous symptoms nor edema returned from that time on. This would suggest that for permanent raising of the blood calcium the viosterol were the best therapeutic agent. However, the possibility that by this time some deficiency in the body defenses had corrected itself must be considered.

That cases presenting these symptoms might be cases of tetany of the new-born was first mentioned by Kehrer. The nervous symptoms shown by his cases were practically identical with those recorded here. Von Reuss, by refusing to recognize Kehrer's opinions, has been apparently a powerful factor supporting the general idea that tetany is rare or perhaps never exists in infants of this age period. His main argument seems to be that laryngeal spasm was not present or at least not mentioned in this series. Grulee, while a little less dogmatic, still is inclined to disregard Kehrer's report, apparently largely because of the fact that in several of the series other disease was also present. He also states that laryngeal spasm has not so far been recorded in the new-born. He does mention certain hypertonic conditions of the new-born seemingly identical with some of the symptoms recorded in this and Kehrer's cases and considers them as something entirely apart from tetany. Most other writers share the opinions of these men.

The principal arguments against accepting this and Kehrer's cases as true tetany are these: that laryngeal spasm was not shown to be present, that other disease has been present in several instances, that the electrical reactions of tetany have not been shown to be present, that at least a number of the nervous symptoms recorded are relatively common in the new-born and have been considered physiological, and perhaps that the majority of opinion holds that tetany of the new-born does not exist.

As for the first of these arguments is there any sane reason why laryngeal spasm should be demanded as a criterion in tetany of the new-born? True it is common in infantile tetany. On the other hand it is not so frequent in puerile tetany and is rather unusual in adult tetany. To assume that it must be present in tetany of the new-born is to assume that this condition must be identical with infantile tetany, a wholly unfair provision. There is no more good reason for insisting on the presence of laryngeal spasm in tetany of the

new-born than in the adult forms of the disease.

The argument that other disease was present and that therefore the existence of true tetany is to be questioned is also invalid. It is well known that tetany of the infantile period is often brought to light by some intercurrent disease. Falta[12] has mentioned the fact that tetany in older individuals is often brought on by extraneous adverse conditions and Shannon[11] has emphasized the importance of accidental disease processes or other constitutional strain in bringing puerile tetany to light. He compared the affect of the parathyroids in tetany in this respect to the function of the pancreas in controlling diabetes. Lisser and Shepardson[13] also have called attention to this same fact in regard to tetany due to complete removal of the parathyroids during exterpation of the thyroid. The fact that tetany manifests itself more markedly under such adverse circumstances becomes, instead of an argument against, an argument for the existence of tetany during the new-born period, because it emphasizes one more similarity between this and the other recognized forms.

The importance of the electrical reactions must be questioned during this age period since no standard has been established. This is emphasized by the fact that Grulee says that the electrical irritability of the new-born is less than that of older children while von Reuss says exactly the opposite. It is indeed unfortunate that such observations were not possible on the case reported at this time.

The fact that many of the nervous symptoms have been formerly recognized as physiological can be given no credence at all. It is a fact that such symptoms as hypertonia, increased reflexes, clonic movements of the arms on being disturbed and a positive Chvostek reaction may occur in patients who eventually recover without any special form of treatment. However such a fact can not be construed to weaken the importance of observations showing that calcium and parathyroid treatment may accomplish this end quickly.

The fact that general opinion holds that tetany does not exist in the new-born period bears no weight whatsoever since general opinion is so frequently based upon the opinion of one or two outstanding authorities whether they be right or wrong.

On the other hand numerous reasons exist for at least approaching the subject with an open mind. Deficiency of the mechanism controlling calcium metabolism with the resulting symptoms which we are pleased to regard as tetany is not uncommon in older individuals from the period of two or three months on through old age. In fact it is especially common in pregnancy.[10] The inheritive nature of such deficiency is well recognized. I can see no reasonable excuse for assuming that the new-born period should be exempt. In fact there is more excuse for assuming that it might be more prevalent at this time than at any other age period since the traumas incident to birth together with the tremendous upheaval in organic function necessary to continued existence might very well give rise to temporary disarrangements of the body chemistry such as this condition implies. In fact it is my opinion that such is in reality the case. It is indeed interesting, if not significant, that the mother of this infant required calcium therapy to prevent tetanoid manifestations throughout her pregnancy.

The ever present question regarding the relation of parathyroid function to the calcium deficiency in tetany is as pertinent here as in other forms of this disease. That parathyroid deficiency is responsible in the idiopathic forms of tetany of older individuals is almost universally accepted. In the case of infantile tetany the contrary opinion of Howland and Marriott[14] still hinders universal acceptance of such a theory though it is apparently gaining more and more support.[15] Attempts to correlate pathological changes in the parathyroid glands with their apparent deficiency in tetany have been usually unsuccessful whatever the age of the subject and as a result it has been necessary to assume that the failure is a functional one. Similar failure has occurred in this case. So far as is known there was no quantitative or qualitative anatomical deficiency and if we are to hold that the failure of calcium metabolism was of parathyroid origin we must assume that such deficiency was functional in type. This would seem to be the logical opinion to maintain. At the same time it must not be forgotten that the real cause of the symptoms is apparently not the absence of parathyroid secretion but the absence of sufficient active calcium, and that this calcium insuf-

ficiency is probably not so much a quantitative as a qualitative thing. It therefore is perfectly possible that factors far removed from the parathyroid secretion, for instance acid-base equilibrium, may depress or otherwise divert the soluble calcium from its usual function as regards this symptom complex. In spite of such possibility, however, the rapid response of the condition to the administration of parathyroid extract makes it most reasonable to assume parathyroid failure as the cause.

CONCLUSIONS

1. Tetany of the new-born has been considered a rare condition.

2. A case of tetany accompanied by generalized edema is herein reported.

3. The symptoms of tetany and edema appeared during the course of a protracted illness due to a low grade peritonitis, this latter eventually causing death.

4. Both the nervous symptoms and the edema were strikingly amenable to therapy calculated to raise the level of the blood calcium.

5. This therapy consisted of calcium gluconate and calcium chloride by mouth, hypodermic administration of parathyroid extract (Collip) and the feeding of viosterol.

6. Temporary relief only followed the use of calcium and parathyroid extract. Permanent disappearance of the tetany and edema did not occur until viosterol feeding was combined with the use of parathyroid extract.

7. Blood calcium values, if not too low to be considered within the normal range, were at least at a consistently low normal level in spite of vigorous treatment until the symptoms of tetany and edema were permanently controlled, when an average normal value was found to be present.

8. It is therefore reasonable to assume that some disturbance of the calcium metabolism existed which resulted in either a qualitative or quantitative calcium deficiency, this in turn giving rise to the symptoms of tetany and edema.

9. By serial sections of tissue obtained at postmortem three parathyroid glands were found in none of which could any microscopic pathology be recognized.

10. If the parathyroid glands are to be held responsible for the calcium deficiency it is thus necessary to assume that the failure of these glands was functional in nature.

11. Such an explanation for the symptoms of tetany and edema noted in this case is rather favored, though it is fully realized that other internal chemical maladjustments rendering the calcium unavailable for its usual function might also be operative.

The blood calcium determinations and the autopsy in this case were performed by Dr. Kano Ikeda.

CARBUNCLE OF THE KIDNEY*

GILBERT J. THOMAS, M.D., F.A.C.S.
AND
ERWIN W. EXLEY, M.D.,
Minneapolis

CARBUNCLE of the kidney, or staphylococcal suppurative nephritis, is a rare, but definite, type of renal suppuration, and a clinical entity entirely differentiated from the acute embolic renal infections more commonly seen. It is an acute metastatic lesion similar in origin to perinephritic abscess and acute septic kidney. A recent article by Dick[1] states that he was able to find only twenty-seven cases of this condition reported in the British literature. Several German writers, Reschke,[2] Nicholich,[3] Voss[4] and others, have written rather extensively of the condition and have propounded various methods for its treatment.

In 1911 Brewer[5] proved with experimental animals that trauma is an exciting factor in renal infections, particularly in the male patient. The primary focus is usually in the skin, or from acute osteomyelitis.

If carbuncle of the kidney is operated upon early in its course, the lesion is similar to a carbuncle observed in the skin, while later abscesses, either single or multiple, may be found localized in one portion of the kidney or involving the cortex in its entirety. According to Dick,[1] rupture into the kidney pelvis is uncommon, while rupture or extension through the cortex into the perirenal tissues occurs more frequently. The infection is usually unilateral, although Kretschmer[6] reported one bilateral case which terminated fatally. The onset is insidious, as the primary foci or exciting trauma may be overlooked. Pulmonary and other complications are common and the course of the disease is usually quite stormy unless an early diagnosis is made. These facts are illustrated by the following case.

CASE REPORT

The patient was a male, aged thirty-eight years, who was admitted to Glen Lake Sanatorium on October 3, 1928, for diagnosis and treatment of an active tuberculous lesion of the right lung apex.

The history of his illness dated from about August 14, 1928, when he developed a furuncle of the skin of the right thigh. The furuncle was lanced by the family physician, who observed the patient for the week following, and then advised him to return to work. After six days, the patient felt so weak and tired that he had to remain at home. The family physician was called again, and upon examining the patient, discovered an unexplained fever. Sequelæ from the furuncle on the thigh were not considered at that time, and although paratyphoid was suspected in addition to tuberculosis, all laboratory tests were negative.

An internist was called in consultation, who examined the patient and requested an *x*-ray study of the chest. The films revealed an apical tuberculous lesion in the right lung, which was assumed to be active and to be the cause of the patient's nightly temperature of 103 to 104 degrees.

About the middle of September, four weeks after the appearance of the furuncle and two weeks after the appearance of the fever, pus was discovered in the urine. Urinalysis at the onset of the patient's illness had been negative. Examination of the urine for tubercle bacilli was negative. At this time the patient had pain in the lower left chest and left renal area, which was intensified by deep breathing. The pain was still present and slightly increased when he was admitted to the sanatorium, six weeks after the onset of the furuncle.

After admission to the sanatorium on October 3rd, the patient's temperature continued to range from 100 to 103 degrees. Pain was present continuously in the left chest and renal area. The urine contained a trace of albumin, many leukocytes and an occasional red blood cell. Examination of the chest revealed a lesion in the right lung apex which was considered inactive. *The left chest was negative.* Tenderness was complained of upon palpation of the left renal area, although no tumor was felt.

Urologic consultation was requested and we advised *x*-ray examination of the kidney, ureters and bladder. No abnormal findings were reported. Cystoscopy was done on October 11. The bladder appeared normal through the cystoscope. Both ureters were catheterized without difficulty. Indigocarmin returned in normal time and concentration from both kidneys. The ureter catheters were allowed to remain in place for forty-eight hours for drainage, during which time periodic lavage was done. The ureter catheter specimens showed staphylococcus albus on culture from both sides. There were a few pus cells in both catheterized specimens, with possibly a few more from the left than

from the right. Pyelography was not undertaken at that time.

Following the cystoscopy and the continuous renal pelvis drainage and lavage, there was a drop in the temperature for two days. The usual methods of therapy for renal infections, intravenous and otherwise,

Fig. 1. X-ray showing spine drawn to right; psoas shadow obliterated on left.

were employed without result. The patient continued to complain of increasing pain in the lower left chest and renal area, which was aggravated by deep inspiration. The temperature was present daily and rigidity was noticed in the area of the left kidney, particularly over the back.

A diagnosis of perinephritic abscess with lung complications was made. The patient's condition apparently contraindicated any surgical exploration at that time because the medical consultant observed physical findings in the left base which he assumed were tuberculous, a possible metastasis from the right lung apex. No tubercle bacilli were found in the sputum at any time.

An *x*-ray examination of the chest on October 29, twenty-six days after the previous *x*-ray study of the chest and ten days after the first positive physical finding in the left chest, showed the right apex unchanged, but the pleura was thickened over the entire left lung, with evidence of consolidation in the left base.

Urinary symptoms were present and more pus cells were found in the urine. Cystoscopy was repeated on November 12. There was some redness and swelling about the left ureteral meatus, but otherwise the bladder was negative. A pyelogram was made of the left side. This was not normal and was interpreted as an acute pyelonephritis. Stained specimens and cultures from both ureteral specimens revealed staphylococci, but no tubercle bacilli were found.

The patient's condition grew steadily worse; the pain in the chest was more severe and tenderness and rigidity in the left renal area more marked. An enlarging palpable mass was discovered in the region of

Fig. 2. Left pyelogram showing dilatation of minor calyces and broadening of isthmus of all calyces.

the left kidney which was thought to be a renal or perirenal abscess. Operative interference was again discussed, but rejected because of the condition of the patient.

On December 15 another X-ray examination of the chest was made. The shadow seen on the left side was smaller than previously reported. Since no tubercle bacilli were found in the sputum, the left pulmonary lesion was thought to be a metastasis from the left renal fossa.

Eventually we obtained a positive guinea pig reaction from the patient's bowel contents, which were thought to be inoculated by the swallowing of tubercle bacilli from the sputum. This was interpreted as evidence of pulmonary activity. Since the lung lesion in the left chest had not proved to be tuberculous in origin, and since lung complications are quite commonly the result of perinephritic infection, we again suggested exploration of the left renal area.

This was undertaken January 2, 1929. About one-half litre of thick, purulent material was evacuated as soon as the deep fascial plane was incised. One large abscess cavity was carefully explored, but a suppurative kidney was not identified. Drains were placed and the wound closed. The purulent material from the abscess cavity contained no tubercle bacilli, but pure cultures of staphylococcus albus were obtained. Large amounts of purulent material continued to drain from the wound for ten days. The patient's condition improved slightly, but his temperature still ranged from

103 to 103.5 degrees. The urine continued to show numerous pus cells and the white blood count was 20,900.

Nephrectomy was performed on January 12. The kidney was found to lie within a dense, adherent, fibrous envelope. This mass could not be delivered through the wound, as we could discover no cleavage line. After much dissection, the true renal capsule was reached. In doing this, a piece of renal tissue about the size and shape of a cherry freed itself from the kidney mass and fell loose in the wound. This was identified as a bit of sloughed renal tissue from one of the abscesses. The hole in the kidney cortex, produced by this sloughing mass, did not bleed. The true capsule was dissected away from the kidney and a sub-capsular nephrectomy was done. The pedicle was so large that ligation en masse was not possible. A renal pedicle clamp was left in place and sufficed as a drain. The removed kidney was almost entirely replaced by abscess cavities and necrotic tissue.

Fig. 3. External surface of operative specimen, showing abscess and portion of detached renal tissue.

Fig. 4. Bisected operative specimen, showing multiple abscesses throughout.

After nephrectomy, the patient's condition was so critical that continuous supportive measures were necessary. The wound continued to drain for a considerable time after operation. The temperature continued to range from 101 to 102.5 degrees. The urine finally began to show a decrease in pus cells and albumin. The patient's condition improved steadily and drainage gradually ceased. He was discharged from the sanatorium, temperature-free, on April 1, 1929, six months after admission. The last urine specimen examined contained two to four leukocytes per high power field.

Pus persisted in the urine specimens during the presence of the known prostatic infection and it is therefore a matter of conjecture whether or not the remaining kidney is infected or contains a destructive process. The urological tract has not been rechecked and subsequent events will have to be followed in order to establish the soundness of the remaining kidney.

PATHOLOGIC FINDINGS

Gross Findings.—The kidney was much larger than normal. There were petechial hemorrhages in the renal cortex which could be seen on the surface. The renal cortex was obliterated by multiple abscesses containing thick pus and necrotic material. One abscess in the mid-portion had ruptured through to the capsular surface of the kidney.

Microscopic Findings.—The capsule was partly destroyed and slightly infiltrated with lymphocytes and polymorphonuclear leukocytes. There were several small subcapsular hemorrhagic areas. The renal cortex showed marked proliferation of connective tissue elements and exudative reaction. There was a very marked infiltration with lymphocytes, polymorphonuclear leukocytes and plasma cells and there were numerous multilocular cortical abscesses well walled off. There were numerous hyaline glomeruli, several of which were atrophic and others obscured by polymorphonuclear and lymphocytic infiltration. The tubules showed the lumina filled with hyaline material and some pus, and the tubule cells were frequently hydropic.

Pathologic Diagnosis.—Acute suppurative pyelonephritis.

SYMPTOMATOLOGY

For convenience, the symptomatology of carbuncle of the kidney may be classified as general, local and urinary.

General Symptoms.—Chills and fever may be constant or intermittent, usually ranging from 100 to 104 degrees. Malaise, headache and the common symptoms of sepsis, together with leukocytosis, are present. These are always accom-

panied by increasing weakness of the patient, in spite of symptomatic treatment.

Local Symptoms.—Pain is of varying degree early in the course of the disease, but later becomes constant in the affected side. The pain may be in the chest of the affected side, due to reference or actual pulmonary extension, and is increased on deep respiration. Localized tenderness and rigidity on the affected side increase with the progress of the lesion. A tumor mass may or may not be present, although late in the course of the disease it is always present in the average individual.

Urinary Symptoms.—Urinary symptoms may be insignificant or absent. Examination of the urine may be negative early in the course of the disease, while minor urinary findings may be constant throughout. Rupture of the carbuncle into the renal pelvis results in exceedingly large amounts of pus, blood, bacteria and necrotic material in the urine. Urine from the affected side may be sterile before this occurs.

DIAGNOSIS

A careful and thorough history is of the utmost importance in establishing the diagnosis. If the clinician finds a patient between twenty and sixty years of age, who is toxic, with increasing weakness and a history of direct or indirect trauma over the kidney area on either side, he should be on the alert for a suppurating lesion in the kidney. A history of felon, carbuncle, furuncle, acute osteomyelitis, or infected eczematoid lesions, should remind the clinician of the possibility that these infections may metastasize to the renal or perirenal tissues. Pain in the chest with fixation of the diaphragm may lead to a suspicion of pneumonia, pleurisy or other pulmonary pathology. It must be remembered that the urinary symptoms may be very insignificant early in the disease and are therefore likely to draw the attention of the diagnostician away from the urinary tract.

In the later stages of the condition, constant pain, tenderness and rigidity, together with increased urinary findings and the palpation of a tumor mass, render the diagnosis obvious, especially if the patient has been toxic for many days. Leukocytosis is usually high and constant, from 10,000 to 30,000 cells per cu. mm., while the temperature ranges from 100 to 104 degrees.

When rupture of the lesion into the kidney pelvis has occurred, the pyelogram may make the diagnosis. In cases where rupture has not occurred, the pyelogram may be an invaluable aid in ruling out other pathologic conditions of the kidney. The differential diagnosis between carbuncle of the kidney and acute septic or embolic kidney may be very difficult and in many cases impossible.

Bacteriologic studies of the urine by culture may be a valuable aid in the establishment of the specific causative organism, which is usually a staphylococcus of the hemolytic type. Mixed infection may render this finding valueless or misleading.

TREATMENT

Great care should be exercised in the surgical treatment of perinephritic abscess, in order that a primary suppurative process in the kidney may not be overlooked.

Nephrectomy is the treatment preferred by the majority of the writers on the subject, and it has been recommended by Kretschmer, Voss, Barth, Israel and others. The operation should be performed as soon as the diagnosis is established. In many cases of long-standing suppuration, the drainage of a perinephritic abscess with secondary nephrectomy may be necessary, as governed by the condition of the patient. It is possible that many cases of perinephritic abscess in which nephrectomy is necessary eventually, are cases in which the diagnosis of the primary site of suppuration was originally overlooked.

In cases where the suppurating area in the kidney is small, partial resection of the affected portion of the kidney has been recommended by some writers, notably by Reschke.[2] Decapsulation of the organ has been recommended by Nicolich[3] in some types of cases.

This patient has been undergoing prostatic massage for a chronic prostatic infection which contains staphylococci. He has had a recurrence of boils in the skin of his back, but his general conditions has improved so that he is able to attend to his usual duties better than at any time during his life.

CONCLUSIONS

Our study of this case and our review of the literature has taught us the following facts:

1. The presence of a felon, carbuncle, furun-

cle, acute osteomyelitis or infected eczematoid lesion may produce an acute metastatic lesion in one or both kidneys. Complete rest and careful treatment of these foci, together with protection of the kidneys from trauma, may prevent carbuncle of the kidney.

2. The possibility of a renal lesion must be considered when temperature, malaise or prostration follows the severe infections mentioned above.

3. Urinary symptoms and findings may be negative.

4. In spite of evidence of other disease, an acute kidney infection must be expected following such severe infections as those mentioned above.

5. Lung complications are no contraindication to operative treatment, but are quickly relieved because they are the result of metastasis from the kidney.

6. Nephrectomy is always necessary; whether it should be a one- or two-stage operation will depend on the condition of the patient.

PLASMOCHIN

"Plasmochin Compound" is stated by the manufacturer to be "sugar coated pills containing 0.01 Gm. of Plasmochin and 0.125 Gm. of quinine sulphate." The only way in which Plasmochin may be characterized as "extremely dangerous" is that its safe (but efficient) dose is much smaller than that of quinine. Its most important untoward effect is cyanosis due to methemoglobin formation. Abdominal pains have also been produced by it. It is liable to cause the symptoms of cinchonism, such as tinnitis and dizziness; and it has been charged with favoring the occurrence of blackwater fever. The Council on Pharmacy and Chemistry published a preliminary report on Plasmochin in 1927, when the product was not being marketed in this country. Now the Winthrop Chemical Company markets "Plasmochin Compound" but has not taken steps to make this preparation accepted for New and Nonofficial Remedies. (Jour. A. M. A., May 3, 1930, p. 1429.)

THE SEAL OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE COMMITTEE ON FOODS

The seal may be used in advertising in circulars and on packages after acceptance of the product is announced. The seal, if it appears on the package, must be the only seal of such character and must not appear in conjunction with the seals of any other investigative organization. The seal is to be used without any comment by the advertisers, unless such comment has been submitted to the Council or the Committee and approved by them. Should the product, for any reason, become unacceptable, all use of the seal must be discontinued within six months. Only the seal authorized by the body accepting the product shall be used in advertising the product. Products exempted by either the Council or the Committee shall be permitted to be advertised in publications of the American Medical Association but the use of the seal shall not be granted in connection with such advertising. (Jour. A. M. A., May 3, 1930, p. 1407.)

DISTANT METASTASIS IN CARCINOMA OF THE CERVIX OF THE UTERUS*

FRANCES A. FORD, M.D.
Rochester, Minnesota

IN treatment by irradiation of carcinoma of the uterine cervix or fundus, the attention of the radiologist is confined, as a rule, solely to treatment at the primary site of the disease and to direct pelvic extension or local metastasis. This practice undoubtedly has arisen from the assumption that distant metastasis is rare or that it occurs only in the terminal stages of the disease, when intensive treatment is contra-indicated. Occasionally, however, one encounters the necessity of advising treatment for a patient with complete arrest of the pelvic disease, but with evidence of distant metastasis. I have not found reports in medical literature dealing with the question of the radiosensitivity of such metastatic deposits, although the amenability of the primary carcinoma to irradiation is well recognized. The remission of extensive metastasis from testicular tumors under appropriate irradiation has been frequently reported. Leddy recently emphasized the radiosensitivity of the metastatic deposits in bones from carcinoma of the breast. The favorable response of metastasis from carcinoma of the thyroid gland likewise is recognized; even metastatic deposits in the lungs and mediastinum have disappeared under treatment. The present study was undertaken to determine, if possible, the prognostic importance of distant metastasis in cases of carcinoma of the cervix and to assemble the data available as to their reaction under treatment.

From 564 postmortem examinations in cases in which carcinoma of the cervix was present, Albers Schonberg reported metastasis in the following frequency: in the liver, 13.7 per cent; in the lung, 4.07 per cent; in the peritoneum, 7.44 per cent; in the pleura, 1.95 per cent; in the kidney, 1.77 per cent; in the spleen, 1.24 per cent; in bones other than the skull, 0.83 per cent; in the heart, 0.7 per cent; in the pancreas 0.35 per cent, and in the thyroid gland, stomach, suprarenal glands, skull and dura mater, muscles, and mammæ, 0.17 per cent (one instance each). Feilchenfield reported metastasis to distant organs in 28.2 per cent of a series of cases; 15.4 per cent of the metastatic growths were in the lungs and liver. No one else has given as high a percentage of metastasis to the lung. Reichelman, in eighty-six cases, found metastasis in forty-nine; the liver was involved in 15.1 per cent of the cases, and the lungs in 4.6 per cent. That the regional lymph nodes lead in frequency as the site of metastasis, and that they are involved relatively early, is indicated by the fact that Wertheim found them involved in approximately 35 per cent of cases in which the primary lesion was operable.

Macallum stated that adenocarcinoma of the uterus developing from the tubular glands of the fundus uteri or from the more complex glands of the cervix, grows slowly in contrast to epithelioma of the cervix. In adenocarcinoma, metastasis is slow, but nodules do appear in retroperitoneal lymph nodes. There are a few cases in which the secondary growths are widely disseminated, and involve peritoneum, liver and other organs.

TABLE 1

INCIDENCE FOUND AT NECROPSY OF DISTANT METASTASIS FROM CARCINOMA OF UTERINE CERVIX (WERTHEIMER)

	Incidence of metastasis in various organs, per cent*	
	Irradiated (54 cases)**	Not irradiated (50 cases)**
Lungs	11.0	16
Liver	25.9	14
Spleen		4
Suprarenal glands	1.85	2
Heart	1.85	
Bones	1.85	2

*The brain was not examined. Metastasis in some organs which Wertheimer did examine is not reproduced here.

**Distant metastasis was present in 28 of the 54 patients (51.85 per cent) and in 27 of the 50 patients (54.0 per cent).

*From the Section on Therapeutic Radiology, the Mayo Clinic, Rochester, Minnesota. Submitted for publication May 15, 1930.

TABLE 2

SUMMARY OF DATA IN CASES IN WHICH PULMONARY METASTASIS TOOK PLACE FROM CARCINOMA OF THE CERVIX OF THE UTERUS

Case	Age, years	Type of carcinoma	Duration and extent of disease prior to discovery of pulmonary involvement	Symptoms referable to pulmonary involvement	Report of roentgenographic examination of thorax	Treatment after admission to clinic	Duration of life after diagnosis of thoracic metastasis
1	55	No biopsy	Hysterectomy one year before, extensive pelvic recurrence	Nonproductive cough	Diffuse involvement, miliary type, both lungs	None to thorax, treatment to pelvis for relief of pain	Died within one month
2	48	Squamous-cell epithelioma, graded 4	Six years, metastasis to both tibiæ	None	Multiple regions of metastasis	None to thorax, treatment of regions of skeletal metastasis	Died three months later
3	38	Squamous-cell epithelioma, graded 4	Six months, under treatment for three months with satisfactory arrest of pelvic disease	Sharp pain under right scaphoid, dry cough four months before diagnosis	Multiple regions of metastasis, both lungs	High-voltage roentgen rays to thorax	Died three months later
4	24	No pathologic report available	Carcinoma of cervix for five years, radium treatment elsewhere	Nonproductive cough	Multiple regions of metastasis on right side	None	Died in eleven months
5	32	Squamous-cell epithelioma, graded 4	Almost two years, under radium and roentgen-ray treatment second year, fairly well controlled	Dry, irritating cough and dyspnea for one month	Multiple regions of metastasis, both lungs	High-voltage roentgen rays to thorax for palliation	Died in about eight months
6	41	Adenocarcinoma, graded 4, with regions of colloid	Nine months, radium treatment elsewhere, cervical and supraclavicular nodes involved, massive pelvic involvement	Loss of weight and strength, breathlessness and palpitation	Multiple regions of metastasis	High-voltage roentgen rays to thorax for palliation	Died in about eight months
7	47	Squamous-cell epithelioma graded 2	One and a half years, under treatment at clinic six months, increasing pain	None	Multiple regions of metastasis, both lungs	None to thorax, treatment to pelvis for relief of pain	Died one month later
8	54	Papillary adenocarcinoma, graded 2	Two and a half years, hysterectomy in June, 1929, no extension beyond uterus and cervix noted at operation	None	November, 1929, multiple regions of metastasis in lungs	None to thorax, treatment for skeletal metastasis	No report
9	60	Carcinoma of fundus	Hysterectomy two years and eight months before	Cough of increasing severity, dyspnea after two months	Massive nodes at left hilum and left middle region of thorax, fluid at left base	High-voltage roentgen rays to thorax for palliation, treatment interrupted on account of reaction	Died two months later

TABLE 2—*Continued*

SUMMARY OF DATA IN CASES IN WHICH PULMONARY METASTASIS TOOK PLACE FROM CARCINOMA OF THE CERVIX OF THE UTERUS

10	49	Squamous-cell epithelioma, graded 3	One year and six months, under treatment by radium and roentgen rays, made some improvement, then pelvic disease again became active, cachexia	Chronic cough, not not distressing	Metastasis in left lung	None to thorax	Alive three months later, in poor condition
11	52	Papillary adenocarcinoma, graded 3	Two years six months, moderately advanced, under treatment by radium and roentgen rays became quiescent for over one year, then recurred	Weakness, no cough. Has had colds during winter	Extensive metastasis both lungs	None to thorax	Alive three months later, in poor condition
12	39	Squamous-cell epithelioma, graded 3	Two years, one year under treatment, with temporary arrest	None	Multiple regions of metastasis	None	Died six months later
13	56	Adenocarcinoma graded 3	Two years, satisfactory arrest of pelvic disease in last six months after radiotherapy	Dry cough recently lasting only one week	Multiple regions metastasis, both lungs	None	Alive one month later

In the early period of radiotherapy some apprehension was expressed that irradiation would increase the frequency of carcinomatous metastasis to distant organs. This view was expressed by Prochowneck, who noted the extreme rarity of these conditions after surgical treatment. Adler, in his monograph on radium therapy, stated that with the rarity of regional metastasis, and especially of metastasis to distant parts of the body in cases of carcinoma of the cervix, the relative frequency of them under radium treatment is doubly striking. He considered this fact as undoubtedly directly attributable to the influence of the radium treatment; the periphery of the tumor had received too little irradiation and, as a result, had become especially prone to proliferation. This idea of a stimulative effect from inadequate irradiation has been thoroughly refuted. Wertheimer has compared results of a series of postmortem examinations in cases in which irradiation was done with results in a series in which irradiation was not carried out. Her figures are given in Table 1.

For the purpose of this study the incidence of metastasis found at necropsy is of less significance than the incidence of such lesions noted in clinical examinations during the period when, on the basis of the pelvic disease and the patient's general condition, radiotherapy is warranted either for palliation or in an attempt to arrest or cure the malignant process. A review of a large number of cases has convinced me that such data would be extremely unreliable unless roentgenographic examinations were included at each examination, and great care was taken in recording negative data. Dyspnea of moderate degree is a common complaint in this disease, is most often the result of anemia and weakness, and by most clinicians is not considered suggestive of pulmonary metastasis. Analysis of symptoms in cases of pulmonary metastasis (Table 2) shows that a nonproductive cough is the most common feature but that often it is not sufficiently annoying for the patient to mention it unless she is questioned directly. The patient with even extensive metastasis may be entirely unaware of any respiratory distress. A small series of twenty-five necropsies in cases of carcinoma of the cervix performed at The Mayo Clinic includes two cases of pulmonary metastasis, neither of which had been detected in the clinical examination. In one case, roentgenogram of the lungs

TABLE 3

SUMMARY OF DATA IN CASES IN WHICH SKELETAL METASTASIS TOOK PLACE FROM CARCINOMA OF THE CERVIX OF THE UTERUS

Case	Age, years	Type of carcinoma	Duration and extent of disease prior to discovery of skeletal involvement	Treatment previous to occurrence of metastasis and result of treatment	Symptoms of metastasis to bones	Report of roentgenographic examination	Treatment of metastasis	Effect of treatment, if any	Subsequent treatment and effect	Duration of life after diagnosis of skeletal metastasis
1	54	Papillary adenoma, of uterus and cervix, graded 2	2.5 years	Hysterectomy four months before, no pelvic recurrence	Pain in left leg and knee	Destruction of inner condyle of left femur	Moderate-voltage roentgen ray to knee	Definite relief of pain for short period, pain returned with diathermy	Moderate-voltage roentgen ray one month after previous treatment, no effect to time of dismissal	No report (thoracic metastasis diagnosed at last observation)
2	56	Adeno-carcinoma	Extensive carcinoma of cervix 3.5 years before	Radium and roentgen rays, complete relief of symptoms, massive pelvic recurrence	Swelling of legs	Multiple regions of rarefaction in right ilium, probably metastasis	High-voltage roentgen rays	Great palliation immediately which continued over 3 months		Died 4 months later
3	48	Squamous-cell epithelioma, graded 4	6 months extensive pelvic disease	Radium and roentgen rays 2 months before with marked improvement	Pain in right leg below the knee	November, 1925, region of destruction in right tibia, February, 1926, region of destruction in tibia larger and metastasis in lower third of left femur and left tibia, January, 1926, pulmonary metastasis noted	November, 1925, moderate voltage roentgen rays to right tibia	Decided relief of pain but no retardation in development of metastasis	January, 1926 moderate-voltage roentgen rays	Died 5 months later
4	59	Adeno-carcinoma graded 3	10 years	Amputation of cervix, 1919, total hysterectomy for recurrent carcinoma of cervix 1921, prophylactic treatment by radium and roentgen rays, no pelvic recurrence	Stiffness of right knee and edema of right leg, severe pain	Region of destruction in right ilium, also palpable mass attached to inner surface of ilium	March, 1929, high-voltage roentgen rays to pelvis	Edema reduced, pain less	May, 1929, no roentgenographic change in region of destruction	October, 1929, very poor condition
5	65	No data	Advanced disease, duration unknown	2.75 years; radium and roentgen rays two years before	Indefinite pain in back and pelvis interfering with walking or climbing stairs, supraclavicular nodes involved	Region of destruction in right ilium	High voltage roentgen rays for relief of pain, treatment to cervical nodes	Complete relief for 3 months	None	No later report

		lioma, graded 3	carcinoma of cervix, 6 months	with complete arrest of pelvic disease	of muscles of left leg	(roentgenographic examination negative one month earlier)	gen rays	during treatment	ered inadvisable	
7	68	Squamous-cell epithelioma, graded 4	2 years extensive carcinoma of cervix	Treatment by roentgen rays elsewhere	Severe pain in right leg, relieved by treatment by roentgen rays elsewhere but patient unable to use leg	Large region of metastasis in greater trochanter and shaft of right femur	High-voltage roentgen rays and radium	Not reported	None	Lived 6 months
8	46	Squamous-cell epithelioma graded 4	6 months	Total hysterectomy, vaginal fistula repaired	Throbbing pain in head, also pain in right leg and back 9 months after operation	Metastasis in skull; lumbar part of spinal column, pelvis and thorax negative	None	Rapid increase in regions of destruction in skull in 1 month	None	No report
9	53	Squamous-cell epithelioma, graded 4	3 years	Hysterectomy	Pain in hips and back, starting soon after operation, increasing in severity for three months to time of observation	Small region of destruction in fourth lumbar vertebra and furring of disk, possibly tuberculous	Radium needles to small recurrent growth	No report	None	No report
10	54	No data	10 months carcinoma of uterus with vaginal involvement	None	Severe backache	Complete destruction of ramus of right pubic bone	None	None	None	Unknown
11	44	Squamous-cell epithelioma, graded 3	1 year, 3 months	Cautery to cervix, vaginal hysterectomy, postoperative radium and roentgen rays	Constant ache in hips and back starting 1 year after operation	Destruction of lumbar vertebræ, second, third and fourth, diagnosed 4 months after onset of pain	None	None	None	Unknown
12	49	No biopsy	4.5 years (very extensive pelvic disease when first examined)	Radium and roentgen rays with 4 years arrest of disease	Pain in left hip	Extensive destruction in right ilium (8 months after onset of pain)	None	None	None	Died 5 months later
13	59	No biopsy	Moderately advanced pelvic disease symptoms for 5 months	Radium and roentgen rays	Pain in right ankle, with swelling 3 months after treatment	Metastasis in lower third of right tibia	None	None	None	Died 6 months later
14	60	Carcinoma of fundus	2 years 8 months	Hysterectomy	Pathologic fracture first symptom	Destructive lesion in right femur with pathologic fracture	None			Died 2 months later

had not been made; in the other case, the roentgenogram taken one month before death failed to reveal the lesion.

Severe and often intractable pain in the lumbar or sacral regions radiating into the legs is one of the most common symptoms in advanced carcinoma of the cervix. This is usually attributed to impingement on the sciatic nerve or the lumbar plexus, or to compression of the ureters with resultant hydronephrosis. The clinician or radiologist rarely seems to make an effort to determine the exact origin of the pain.

In a study of twenty-four patients with uterine carcinomas, thirteen of whom had metastasis to the lungs, and fourteen metastasis to the bones, I have indicated the stage of the disease at which metastasis was recognized, the type of malignancy in each case, and the significant symptoms and their severity.

Data concerning the cases in which pulmonary metastasis took place are given in Table 2. Metastasis of both adenocarcinoma and squamous-cell epithelioma took place, with malignant characteristics graded from 2 to 4, according to the classification of Broders. There was satisfactory eradication or control of the pelvic disease by either surgical or radiotherapeutic treatment in four cases; in the others, active carcinoma was present in the pelvis. The freedom from distressing symptoms in the majority of cases of the group is especially notable, and indicates the probability of overlooking secondary growths, except through roentgenographic examinations made as a routine. Three patients in whom pulmonary metastasis has been discovered recently are living. The remainder died in from one month to eleven months after the pulmonary lesions were detected. In only three cases (treatment was abandoned in a fourth case because of reaction) was any attempt made to arrest the development of the pulmonary growth by irradiation, and in these cases, through accidental circumstances, there has not been an opportunity to trace the result of such treatment by later roentgenographic or clinical study. When there is evidence of rapid dissemination of the carcinoma, with general cachexia, the radiologist is scarcely justified in applying extensive radiotherapy. Probably only rarely will a patient be found who is in good general condition, with other manifestations of disease in satisfactory control, for whom a trial of intensive irradiation for pulmonary metastasis is warranted. In such cases, from the radiologist's point of view, treatment should be pushed energetically until sufficient experience has proved or disproved the possibility of influencing the development of pulmonary invasion in this type of carcinoma.

In Table 3 is presented a summary of clinical data in regard to the fourteen cases in which metastasis to bone took place. Pain seems to be an invariable symptom of this form of metastasis, but with concomitant adnexal infiltration, the causative factor underlying the pain may be in doubt. Malignant deposits in the lower extremities had been regarded as infectious destructive processes in two instances, and their malignant nature was recognized only as the disease became manifest elsewhere. In one instance, destruction of the right ilium occurred ten years after hysterectomy for the primary disease, with no evidence of local recurrence. Palliation has resulted from radiotherapy in some instances, although there are often complicating factors to consider in explanation of the relief of pain. In the few cases concerning which we can form an opinion, the relief of pain has seemed to be less definite and prolonged than that experienced in the treatment of metastasis to bone from carcinoma of the breast.

CONCLUSIONS

1. Metastasis to distant regions, from carcinoma of the cervix and fundus of the uterus, occurs more frequently than is ordinarily assumed.

2. Pulmonary metastasis often is not accompanied by distressing symptoms, so that only by frequent roentgenographic examination is it detected in the early stages.

3. The presence of metastasis in bones often is overlooked because of complicating circumstances which may account for pain. Metastasis to the extremities or skull often is mistakenly attributed to inflammatory destructive lesions.

4. Some relief of pain may be secured by effective irradiation of metastatic growths in bone from carcinoma of the uterus. This response seems less definite and less prolonged than that obtained in secondary growths from carcinoma of the breast.

5. There are not sufficient clinical data to warrant an opinion as to the radiosensitivity of pulmonary metastasis from uterine carcinoma. From the standpoint of greater precision in the application of radiotherapy a fair trial of such treatment in well selected cases should be made.

CASE REPORT

PULMONARY ASBESTOSIS: REPORT OF A CASE*

RALPH G. MILLS, M.D.,
Fond du Lac, Wisconsin

Interest in the injury to the lungs produced by the inhalation of asbestos dust has been aroused in the last six years, and several reports of cases have appeared in the medical literature of Great Britain. Aside from an occasional editorial or incidental mention, little has been written in this country about the condition. Apparently this is the first case reported from the United States. Nevertheless asbestos is mined or manufactured in many portions of this country. Undoubtedly injury to the lungs of some of these numerous workers has occurred, and may have been directly or indirectly responsible for death without the real condition being recognized. This case is reported in the hope of arousing more widespread interest in the disease and establishing it as an entity with which American physicians surely will have to deal.

REPORT OF CASE

A man, aged fifty-eight years, came to The Mayo Clinic May 26, 1929, in extremis, suffering from cardiac disease. He was taken to the hospital immediately on his arrival, and such studies were made of the disease as his condition permitted. Not a great deal was then known of his earlier history except that as a boy he had travelled the seven seas with his grandfather, who was a sea captain. He lived well and drank heavily during this period of his life. For a number of years he remained in the tropics, and finally, in 1898, contracted yellow fever. After recovery from this disease he returned to the United States and engaged in various enterprises, among others, the manufacture of brick. Subsequently, it was ascertained that the patient had been working in South America from 1911 to 1913; the significance of this fact will appear later. Aside from the illness due to yellow fever, he was thought to have been in good health until 1924, when he had an attack of dyspnea, with mild, but increasingly severe, congestive heart failure. Five distinct attacks, characterized by these same symptoms, had been experienced before the last seizure, which occurred in December, 1928, following a type of respiratory infection called influenza.

General examination revealed that there was dyspnea, cyanosis, and congestion of the lungs. The systolic blood pressure was recorded as 160 mm. of mercury, and the diastolic pressure, as 110 mm. The heart was enlarged, and there was a systolic murmur at the apex. Ascites and edema of dependent portions were present, and the liver was large and tender. Examination of the ocular fundi disclosed sclerosis of the retinal arteries, of the hypertensive type, with two small hemorrhages in the retina. Roentgenologic examination of the thorax gave evidence of an enlarged heart, and of passive congestion of the lungs. This plate, however, was taken in the hospital and was not satisfactory for further analysis of the condition of the lungs. Electrocardiographic examination gave evidence of complete heart block.

During the patient's stay in the hospital he failed rapidly and dyspnea, cyanosis, and edema increased. The pulse became very irregular and manifested auricular fibrillation. There was venous congestion in the neck. Venesection was performed twice, and salyrgan, 1 c.c., was given intramuscularly once, and just before death by vein. The patient died two days after he entered the hospital. The clinical diagnosis was hypertensive cardiac disease of five years' duration, cardiac hypertrophy with congestive failure, of five months' duration, and complete heart block.

An abstract of observations at necropsy includes the following points of significance. The abdomen contained 4,000 c.c. of clear, straw-colored fluid. There were 300 c.c. of a similar fluid in each pleural cavity, and the pericardium contained 200 c.c. The heart weighed 600 gm.; the myocardium was yellowish pink, and beneath the epicardium were a few petechial hemorrhages. The consistence of the muscle was firm, and the surface presented a moderate amount of streaking. The coronary arteries were slightly sclerosed. The measurements of the heart were as follows: aortic valve ring, 7.0 cm.; mitral valve ring, 11.0 cm.; tricuspid valve ring, 14.0 cm.; pulmonic valve ring, 7.0 cm.; thickness of left ventricle, 1.8 cm.; depth of left ventricle, 6.0 cm.; thickness of right ventricle, 0.5 cm., and depth of right ventricle, 10.0 cm.

There were interlobar adhesions of the left lung, and the anterior surface of the lower lobe was covered with fibrous adhesions. Both lobes were grayish-brown and mottled, with anthracosis, marginal emphysema, and apical scarring. The consistence of the tissue of the lung was markedly increased. On the cut surface the color was recorded as grayish-brown, and the froth and fluid that exuded were increased in amount. The upper lobe of the right lung was of the same color and general appearance as the left; it was partly covered with adhesions. Apical scarring was noted in this lung, and there was also subpleural edema. The condition of the middle and lower lobes was essentially of the same nature; the lobes were united by interpleural adhesions. A calcified node of the hilum was found.

The liver was purplish-brown, coarsely nodular, and the cut surface was finely granular. There were scat-

*Work done in the Section of Pathologic Anatomy, The Mayo Clinic, Rochester, Minnesota.
Submitted for publication May 29, 1930.

tered regions of thickening in the capsule. The cut surface was mottled yellow and red, and there was definite fatty change in the hepatic parenchyma.

The anatomic diagnosis that was given took account of the features just mentioned and included a notation of silicosis of the lungs. Microscopic examination of the essential tissues was made. Numerous phagocytic cells that contained quantities of blood pigment were noted in the alveoli of the lungs. Special stains for iron demonstrated its presence in these cells and also in the walls of blood vessels and alveoli. There appeared to be some increase in the amount of readily visible elastic tissue in the lung. Fibrosis was very marked.

Fig. 1. A large mass of asbestos, measuring more than 1 mm. in length, obtained from the lung by digesting a portion of the tissue with fuming nitric acid. Evidence of degeneration is the presence of the cross striations in the fibers. The darker portion of the fiber had a distinct yellowish-brown color (x75).

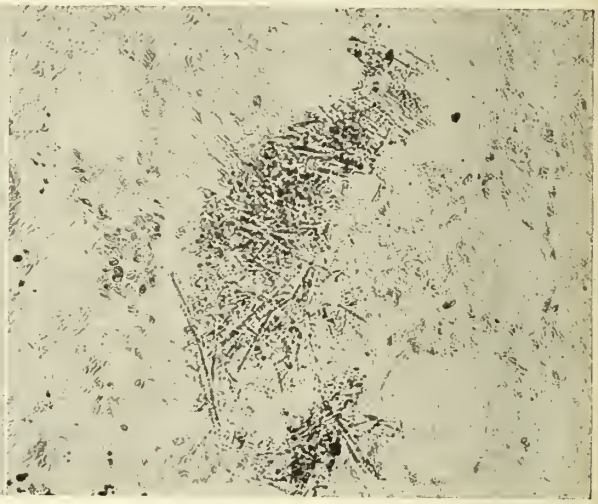

Fig. 2. A tangled mass of asbestos fibers in an unstained section of pulmonary tissue. From its distribution one would suspect that it had been dilodged by the microtome knife. The scattered black dots are "asbestosis bodies," indicating that a portion of the fibers, at least, had undergone change in the tissues (x175).

COMMENT

During the final survey of the sections in this case there were observed certain peculiar, brownish, fibrous structures, apparently foreign bodies, in the tissue from the lung, usually embedded in connective tissue, and often engulfed by large giant cells. They did not take the ordinary stains, and some of them were shown to contain iron by the Prussian blue reaction. There was much discussion as to the nature of these bodies, without any conclusion being reached. The possibility was considered that they might be asbestos fibers, but at that time there was little basis for such a contention. There was no history of exposure to asbestos dust, and certain apparent differences were observed between the reactions of these fibers and those shown by commercially prepared asbestos. However, further study strengthened rather than weakened the impression that the bodies were asbestos fibers. Evidently the fibrosis of the lungs was in some way connected with the presence of these foreign bodies. The idea was further entertained that the fibrosis of the lungs was responsible for progressive increase in resistence to the circulation through the organs, and may have led to hypertrophy and finally to dilatation of the right side of the heart. The systolic pressure of the blood was not greatly elevated when it was recorded, but the diastolic pressure was relatively too high. The heart weighed as much as many hearts in cases in which hypertension was the underlying lethal factor. The complete heart block was hardly to be explained on the basis of partial obstruction. There seemed to be no final answer to several questions connected with the case.

Shortly after the death of this patient, I corresponded with one of his business partners, and mentioned the fibrosis of the lungs. I also wrote that the fibers found looked more like bits of asbestos than anything I could think of, and asked if, fifteen years or more before his death, the patient could have been exposed for any considerable time to inhalation of inorganic dust such as asbestos, or any material that would give sharp, angular particles as well as longer, irregular fibers.

More than eight months after this letter was written, a business associate called on me, and stated that he had ascertained that the deceased had, as a young man, worked in an asbestos mine in South America. Later still, another business associate wrote that while the patient had been in South America he had drilled asbestos bearing rock. The shot holes were cleaned by air. Presumably this was prior to 1898, when he left the tropics, or at least thirty-two years before his death.

The study of the lungs and heart was resumed, so far as material was available. This unfortunately was limited. A few small pieces of pulmonary tissue were subjected to the action of fuming nitric acid to oxidize all the organic matter, and to concentrate in the sediment any inorganic fibers or other particles that may have been embedded in the substance of the lung. The pulmonary tissue contained a surprisingly large amount

of fat which collected as fatty acid on the surface of the liquid. This was not a clear yellow, and a smear of it was made, with the idea that some of the fibers might have been caught in this material and thus prevented from settling to the bottom of the heavy fluid. The sediment collected from the bottom, after washing, was found to contain a few fibers, together with some small particles of silica. Such drastic treatment as boiling in fuming nitric acid would destroy most materials, even the finest fibers of asbestos, but would probably not affect appreciably the larger ones.

In the scum that collected on the surface of the solution of nitric acid were found several fragments that were certainly asbestos. The largest was more than 1 mm. in length (Fig. 1). This had the definite cross striations that are characteristic of altered asbestos fibers, as described by various observers.[2] When viewed under polarized light a portion of the mass was dark and there were brilliant streaks through it, thus duplicating the appearance given by a known sample of asbestos from commercial sources. A portion of the mass of asbestos had a yellowish-brown color of exactly the nature and shade presented by the control sample. The physical configuration also agreed with what one would expect of asbestos.

In Figure 2 are shown the asbestos fibers in a smear where they apparently had been spread through the tissues by the microtome knife. The section in which they were found had not been stained. A few golden-brown oval bodies were mixed with the fibers, suggesting that some alteration in their structure had taken place, but the condition of the main mass indicated that the center had been protected from this change in the tissues. Alteration apparently affected mostly the finer fibers, leaving the larger masses relatively unchanged for this long period of time. Search was made for the elastic tissue fibers about the blood vessels, and in the alveolar walls, but they could hardly be distinguished. These asbestos fibers did not show more plainly by polarized light. The golden-brown color of the fibers was a distinguishing feature under the microscope.

Smaller fibers of asbestos, when lying separate, seemed to have undergone changes not observed in larger fragments. The butt end of one of these fragments is shown in Figure 3. It had become enlarged and knobbed, and had a distinctly brownish color. There seemed to be an envelope of a lighter brownish color about a darker center; the latter was continuous with the fiber inside the giant cell. The frayed ends of the fiber gave place to the golden-brown oval bodies, whereas that portion within the giant cell was the least changed. The majority of asbestos fibers of small size lay in a confused mass of giant cells, which seemed to represent a foreign-body reaction. In Figure 4 is shown a scattered group of fibers, among which can be seen giant cells; the adjacent tissue of the lung has been undergoing interstitial fibrosis. The asbestos fibers were readily distinguished from elastic tissue fibers by their golden-brown color; the fibers of elastic tissue took a lilac-brown stain with hematoxylin. The former were unchanged by ordinary aniline dyes, whereas the latter were readily tinted by various methods usually applied to such tissues.

In certain areas the process was still more advanced and connective tissue of a more mature type was seen, sometimes in more or less circumscribed areas. Such a nodule of scar tissue is shown in Figure 5, but this is not entirely comparable to the so-called silicotic nodules found in cases of silicosis in which tuberculosis plays a part.

There seemed little doubt that many of the asbestos fibers had been almost completely removed from the tissues. The frequent association of partly absorbed fibers and the golden-brown oval bodies shown in Figure 6 leaves little doubt that the latter were derived from the former. They were often in the same giant cell,

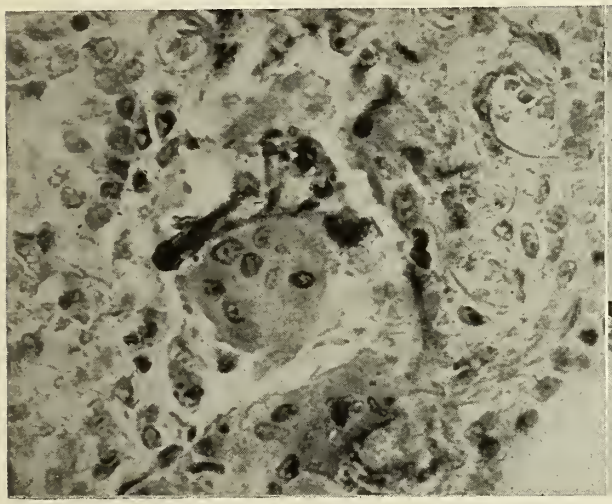

Fig. 3. A small fascicle of asbestos lying in a giant cell. A knob with a brownish envelope has developed on the butt end of the fiber; the frayed ends opposite have broken off as golden-brown oval bodies (x200).

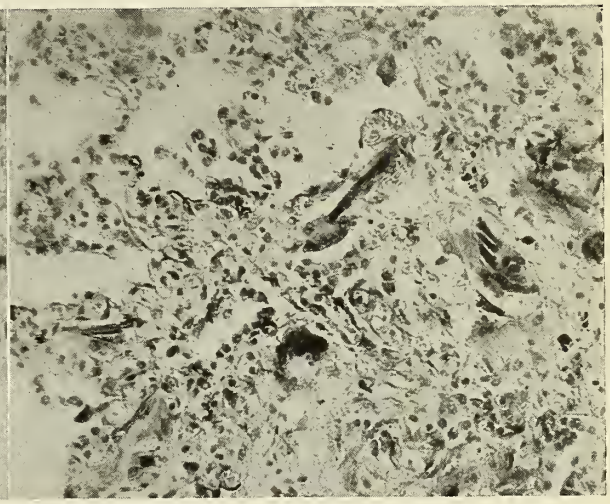

Fig. 4. A group of asbestos fibers surrounded by giant cells. Their golden-brown color distinguished them from fibers of elastic tissue, which stained more of a lilac color with hematoxylin and eosin. The asbestos fibers were frequently thicker and more irregular in outline, and remained unchanged in color with the ordinary aniline dyes (x150).

or lay close to fibers in various stages of dissolution. There was a central, darker portion, which probably represented the remains of a fiber, and which was not dissolved by nitric acid.[3] The outer, lighter brown covering, however, disappeared, and was thought to be a deposit of pigment of endogenous origin, probably

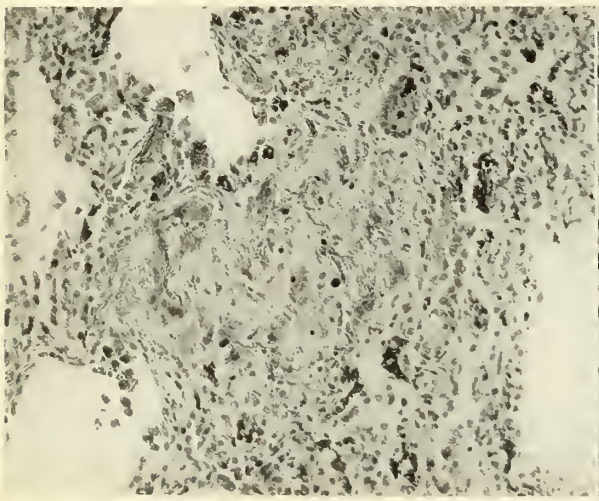

Fig. 5. A circumscribed nodule of fibrosis composed of fibrous tissue and giant cells in the midst of which lie partly degenerated asbestos fibers. The giant cell at the upper edge of the nodule contains several "asbestosis bodies" presumably in the stage of transition between a continuous fiber and the golden-brown oval bodies (x200).

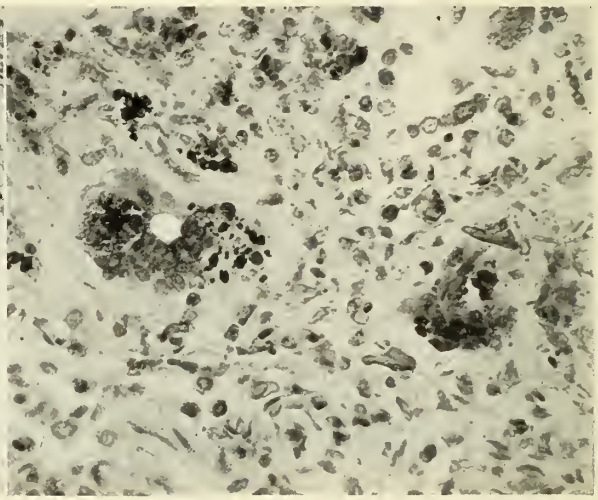

Fig. 6. Two giant cells with inclusions. The one on the right contains a bit of golden-brown asbestos within it, and there is also one above and one below the cell. The cell on the left contains numerous golden-brown bodies and a large vacuole in which lie more of these bodies, together with granules of hematogenous pigment. The tissue is markedly fibrotic (x450).

derived from the blood. It did not take a Prussian blue stain, although there is reason to believe that it contained iron in the form of one of the higher oxides. These golden-brown oval bodies were not birefringent under polarized light. They were believed to represent the end stage of disintegration of fibers of which an intermediate stage has been described by Cooke,[1,2] and by McDonald as "curious bodies" and by Stewart and Haddow as "asbestosis bodies." These men saw cases of more intense nature, and fibers that had not been exposed to the tissues for such a long period of time. The oval bodies did not stimulate the foreign-body reaction to such a marked extent as did the incompletely disintegrated fibers, but were scattered in clumps or singly through regions of mature connective tissue. This may be attributed to the cessation in the release of silicic acid in the colloidal form, a process that is believed to explain the fibrosis in cases of silicosis. Asbestos is a silicate, and hence presumably subject to the same dissolving process that affects particles of pure silica in the production of silicosis.

The ordinary "heart failure cells" presented the usual morphology and staining reactions. Occasional cells of the same general nature as the heart failure cell were found, measuring 100 to 150 microns in diameter. They contained only blood pigment, a few golden-brown oval bodies, bits of degenerated elastic fibers, or any combination of the three.

Perhaps the most valuable feature of this case is the extreme length of time that elapsed between the exposure to the dust and death. A few particles of silica were detected in the tissues and in the residue after oxidation with the acid, but not enough to explain the fibrosis which was present. Apparently once asbestos dust enters the lung it continues to injure the tissues as long as the person lives. In short, asbestosis is an incurable disease, and one from which the patient may or may not die. Intercurrent disease has been found in other reported cases to be unusually frequent, especially tuberculosis and bronchopneumonia. Neither were present in this instance, and death occurred from hypertensive heart disease, with complete heart block. This complication has not been mentioned before in this connection.

There is no reason to believe that the hypertension was directly connected with the pulmonary asbestosis, but the extreme dilatation of the right side of the heart is probably attributable to the fibrosis of the lungs. Passive congestion of the lungs is to be considered as a complicating factor, and may have operated in preventing a possible tuberculous infection. Auricular fibrillation was associated with the cardiac decompensation, and the heart block was probably of similar origin. Infarction of the heart was not found, and only the fatty changes in the myocardium were discovered which also involved the bundle of His. Colloidal silica has been found in previous studies[4] to be injurious to other viscera, especially the kidneys, but in this instance such alterations were not marked. The heart block, then, can hardly be attributed to this toxic factor.

SUMMARY

A case of pulmonary asbestosis, found in the United States, and of at least seventeen years' duration, is described. Pertinent clinical and pathologic details are given. This report corresponds reasonably well with reports from Great Britain.

39 South Main Street.

METATONE NOT ACCEPTABLE FOR N. N. R.

Shotgun tonic mixtures were very popular a generation ago and some received more or less official recognition by being included in the National Pharmacopeia. In recent years these tonic mixtures have deservedly fallen into disuse, although included in the line of preparations of many manufacturers. Occasionally an effort is made to revive the use of such tonics by the addition of an ingredient the use of which has become a current fad. One of the recent attempts in this direction is the exploitation by Parke, Davis & Co. of a typical shotgun tonic mixture, modernized by the addition of "Vitamin B extract." This preparation, known as Metatone, is stated to have the following composition: alcohol, 1 per cent; Vitamin B extract per fluid ounce, 10 grs.; nucleic acid, 2 grs.; calcium glycerophosphate, 4 grs.; potassium glycerophosphate, 4 grs.; sodium glycerophosphate, 2 grs.; manganese glycerophosphate, ½ gr.; strychnine glycerophosphate, 8/200 gr." The statement as to the amount of "Vitamin B extract" is meaningless and gives no indication as to the actual amount of Vitamin B present, and there appears to be no good reason for giving it along with the other constituents of Metatone. Most of the other constituents of Metatone have long since been discredited as useful therapeutic agents. The Council on Pharmacy and Chemistry declared Metatone unacceptable for New and Non-official Remedies because it is an unscientific mixture, marketed under a proprietary name with unwarranted therapeutic claims. (Jour. A. M. A., May 3, 1930, p. 1405.)

ELECTRIFIABLE PLATES

The Post Office Department reports that J. M. Hughes, his wife, Mrs. J. M. Hughes, and his daughter, Essie I. Hughes, all of Atlanta, Ga., have for some time been defrauding the public under the trade name "Electrifiable Company" in the sale of so-called heel plates. These plates were crudely cut from sheets of copper and zinc. They cost 25 cents a pair; they sold at $5 a pair! It was claimed that, when worn in the shoes, the plates would cure hardening of the arteries, high blood pressure, enlargement of the heart, kidney trouble, hardening of the prostate gland, diabetes, rheumatism and dropsy! The Postmaster General issued a fraud order against the Electrifiable Company and J. M. Hughes. (Jour. A. M. A., May 3, 1930, p. 1427.)

USE OF THYROID IN OBESITY

The use of thyroid in obesity should always be controlled by a previous basal metabolism test. If this is normal or subnormal, it is safe for a physician to use thyroid. The best practice is to start with small doses of desiccated thyroid (Thyroideum, U. S. P.) gradually increasing. The small dose would be approximately 0.03 Gm. (½ grain) twice a day. The physician must keep a sharp lookout for fast pulse, nervousness or other symptoms resulting from thyroid stimulation. An obese person should not expect reduction by thyroid unless his diet is restricted, and when dietary restrictions are followed thyroid is not needed as frequently. (Jour. A. M. A., May 31, 1930, p. 1784.)

President's Letter

THE time will never come when the members of the medical profession will cease to seek for more knowledge. They always have done so. They always will do so. That is why they tend to locate where there are other doctors. It is why they establish offices near together, even in the same buildings. It is why they establish medical societies and why they visit medical centers.

So strong is this desire to acquire additional information that they will abandon their work and go from home, often at great expense, to take post-graduate courses of study. When they are not in a position to go away often enough, or stay away long enough, they band together and bring educational courses to their own communities, as witness our extension courses. Perhaps the keynote as to the kind of information sought by these busy men is expressed by the words authoritative and practical.

The program committee of the State Association has borne the latter fact in mind in making up the program to be presented at the meeting in Duluth in July. Every effort has been made to place men on the program who, by virtue of experience and training, can speak authoritatively and who will discuss their various subjects in a lucid and practical manner.

The association has been especially fortunate in its guest speakers. Such men as Prof. Boehler of Vienna, who has revolutionized the treatment of fractures, Prof. Franz Volhard of Frankfort on Main, of kidney fame, W. T. Longcope of Johns Hopkins, Karl Meyer of Northwestern University, Chicago, Ralph Kinsella of St. Louis, E. C. Davidson of Detroit, Michigan, Arnold S. Jackson of Madison and R. S. Dixon of the Detroit Department of Health are generously contributing their services.

There will be symposia. There will be a large range of subjects discussed by trained men affiliated with our institutions of learning, by men who are teaching, by others engaged in clinical work, in private practice. Still others will discourse upon the work of our state institutions. There will be lectures on preventive medicine and a whole evening will be devoted to economics.

The program is alive, up-to-date and thoroughly practical. It offers a tremendous lot of material in a form easy of assimilation. It offers an opportunity to acquire a great fund of medical knowledge within a three-day period. All can afford to come. None can afford to stay away.

S. H. Boyer

President,
Minnesota State Medical Association.

THE ANNUAL MEETING

On to Duluth! Glance at the program of the scientific addresses which appears in this number of the journal and make your plans accordingly.

In former years it was the custom to limit guests from without the state to one or two, the program having been reserved for home talent. In recent years more and more outside talent has been imported and undoubtedly is an attraction. We like to see and hear and meet those whom we have known by reputation only. There is no question but that this phase of most medical meetings is their real *raison d'etre*. The addresses themselves are usually published and can be better digested when read at leisure. The broadening effect of widening one's acquaintance is fully as important as the renewal of acquaintanceship.

Most of us have heard of our distinguished visitors. Who does not know of Volhard by reputation? He is to include the State meeting with his participation in the Kidney Symposium at the University July 7 to 18, and will address the meeting on his favorite subject, the kidney. The tannic acid treatment of burns, which has attracted some international attention, will be presented by its originator, Dr. E. C. Davidson of Detroit. The visit of Professor Lorenz Boehler to this country has attracted considerable attention in medical circles. His reduction method of fractures under local anesthetics and early mobilization of the patient with a special cast and support, will be presented at the meeting.

The scientific exhibits at medical meetings in general have been growing in importance and interest. The display at last year's state meeting was most interesting. To stimulate interest in this part of the scientific program the Southern Minnesota Medical Association has offered a medal for the best scientific exhibit submitted. The exhibits from the Mayo Clinic are excepted.

The scientific program this year will for the first time occupy three full days. Last year local clinics served to fill out the three convention days.

The House of Delegates will meet Monday and Tuesday afternoons. The following Reference Committee has been appointed:

J. R. Manley, Duluth
W. F. Braasch, Rochester
E. M. Hammes, Saint Paul
C. P. Robbins, Winona
C. B. Wright, Minneapolis

The adoption of the Reference Committee method of handling committee reports and resolutions has proved highly satisfactory in expediting the transactions of the House of Delegates.

Shall we meet in Duluth?

THE DOCTOR AS A CITIZEN

The writer has had the opportunity, on the occasion of the meeting in Duluth of the Minnesota League of Municipalities, to hear one of our own active memers, Dr. O. E. Locken, Mayor of Crookston, talk on our affairs to lay audiences. Most of us know of the great interest Dr. Locken has had in various health movements; few of us hear him when he presents to laymen a sane, conservative expression of our medical objectives and an outline of community responsibilities.

It is a pleasure to pay tribute to his consummate skill. We may gain a few points through favorable legislation; we may fortify our professional position by industrious collectivism; but we shall never maintain economic and directional independence unless we are able to sense the times. In the matter of community life doctors expect over much, to be accepted as they are, mantled with a state-given prerogative which virtually amounts to a monopoly. Not always do we attempt to repay the community in which we live by entering fully into the daily movements which are its life.

We like to think that our government exists at our will. But it is rarely indeed that the public really expresses its opinion in anything like mass voting. After elections we drift and criticize our electorate near and far with an abandon that makes office holding and politics something contemptuous or worse. Yet Dr. Locken shows that we have definitely asked our governmental agencies to do endless things for us, few of which we would be willing under any circumstances to see abandoned. Population shifts, pauperism, unemployment, old age pensions, increasing accidental death rates, all present issues that strike closely to the core of the problem of making available to the mass of our population the scientific facts already proven to prolong life and make it worth while. We cannot withdraw into cloistered atmospheres, cheered only by our medical jargon and fancy that a divine right shall entitle us to perpetual leadership and public approval. Such men as Dr. Locken show us the way to a type of citizenship exemplifying an adaptation of our professionalism to our turbulent age.

E. L. T.

THE PRESENT MORALE IN ATHLETIC TRAINING

There is considerable food for thought in an article entitled Booze Beats Our Athletes, by Charley Paddock in the June 14th Collier's Weekly. The author, an athlete himself, is in a position to know, first hand, the present situation in athletic training in high school, college and Olympic teams.

While American athletes may never have shown the superiority in athletic events requiring great endurance that they have shown in the shorter races and events requiring more of the element of skill, the author calls attention to the definite slump in the number of our victories in the Olympic games since so-called prohibition was enacted. Since the war we have not won a single victory in races longer than the quarter mile and this is apparently not because of any demonstrable improvement in the status of athletics in other countries. He attributes the slump to the failure to maintain training, particularly as to the use of alcohol. The numerous incidents which came under his observation of drinking and that to excess, not only during training season but even before a race, are startling. The lack of moral stamina necessary to keep strict training as far as the use of strong drink is concerned, is nation-wide in its distribution and has affected high school, college and international athletics.

The general psychological effect of prohibition has apparently invaded the realm of athletics and the change of public sentiment in regard to the use of liquor has seriously interfered with the morale of athletic training. Before prohibition the athlete who broke training during season by taking a drink of liquor had to contend with the pressure of undergraduate or public opinion, which was so strong that such an offender knew in advance that he would likely be dismissed from the team. Apparently not so now. The lack of moral backing seems to have rendered trainers helpless.

The self-indulgence and disregard for authority manifest everywhere is naturally imitated by the youth of the country and this is the most serious psychological effect of the prohibition law.

OF GENERAL INTEREST

Dr. R. S. Ylvisaker, formerly of Minneapolis, is now located in Fergus Falls.

Dr. E. V. Goltz of Saint Paul was married June 18 to Miss Edith Allen of Minneapolis.

Dr. John F. Madden has opened offices at 842 Lowry Medical Arts Building, Saint Paul, for the practice of diseases of the skin and syphilis.

Summer clinics sponsored by the Chicago Medical Society will be held at the Cook County Hospital, Chicago, August 11 to 22, inclusive.

Dr. R. J. Moe, associated with Dr. W. A. Coventry in the Duluth Clinic, Duluth, spent six weeks in March and April in the New York Lying-In Hospital.

It is reported that Dr. Daniel D. Murray of Duluth has recently been married to Mrs. Blanche Kemerer Lord in Minneapolis. Dr. Murray has long practiced in Duluth, and was at one time City Health Commissioner.

Announcement has been received of the marriage of Dr. Wallace I. Nelson and Miss Gertrude Bergerud, which took place in Minneapolis May 27, 1930. Dr. and Mrs. Nelson are now at home in Underwood, Minnesota.

St. Luke's and St. Mary's hospitals, Duluth, report a very successful combined staff meeting for both hospitals for their regular March meeting. This time saving combination of necessary staff meetings promises well, according to staff members.

Dr. A. J. Henderson of Kiester, Minnesota, is taking a post-graduate course in pediatrics at Harvard Medical College, Boston. His practice is being cared for by Dr. D. M. Daley of Lewiston, Minnesota, a recent University of Minnesota graduate.

Dr. P. F. Eckman, an associate in medicine in the Duluth Clinic, Duluth, recently returned from an Eastern trip to New York, Philadelphia and Ann Arbor. He devoted his studies exclusively to hematology. He reports the field of study of secondary anemias a most unsettled one at this time.

Dr. A. T. Laird of Nopeming, with Mrs. Laird, attended the recent meeting of the National Tuberculosis Association at Memphis, Tennessee. Following the meeting they traveled to the Ozarks, where they visited with relatives. They report the Ozarks to be a wonderland at this time of year.

Ragnar Westman was awarded the medal offered by the Southern Minnesota Medical Association for the most proficient work in the clinical field of medicine and surgery during junior and senior years at the University Medical School. The awarding committee consisted of the Professors of Surgery and Medicine and the Dean of the Medical School.

Dr. E. L. Tuohy of Duluth presented the subject "Non-Tuberculous Lung Lesions" to the April meeting of the Pine-Chisago Medical Society held at Pokegama, and also to a combined meeting of the South Dakota and Sioux Valley Medical societies held at Sioux Falls, South Dakota, May 21 and 22.

The Minnesota State Medical Association has been invited by the Inter-State Postgraduate Medical Association of North America to be represented at the International Assembly of the Association in Minneapolis, October 20 to 24, by a scientific exhibit. Complimentary exhibit space is offered through Edwin Henes, Jr., Executive Secretary of the organization.

Dr. E. I. Lindgren, formerly of Duluth, now living in Finland, has returned to Duluth for a short visit. He practiced in Duluth for a number of years, but returned to his home country about three years ago. He reports Finland in a prosperous condition. He has traveled extensively in Europe, devoting his studies as well as his practice in Finland to roentgenology.

Dr. and Mrs. H. W. Froehlich, Thief River Falls, sailed, June 13, for Europe on the steamship Duchess of York, to travel until September. They first will visit England, then to Paris, from there to Frankfort, Berlin, Dresden, Munich, Oberammergau to see the Passion Play. From Oberammergau they will go to Vienna, Budapest and through the Tyrols. Dr. Froehlich will spend most of his time in Vienna studying the latest developments in surgery at the clinic.

F. Manley Brist, Investigating Attorney for the State Board of Medical Examiners, addressed a luncheon meeting of the Kiwanis Club at Willmar June 24 on current results of medical legislation sponsored by the State Association. In the evening he talked to the Kandiyohi-Swift County Medical Society on related medico-legal affairs. Mr. Brist will be a guest speaker at the annual meeting of the Wabasha County Medical Society to be held in Wabasha, July 10.

The Minnesota Society of Internal Medicine has again offered a prize of $250 to be awarded for the most worthy research work by a Minnesota physician, exclusive of members of the society. These should be submitted before October 1, 1930, to Dr. E. T. F. Richards, Hamm Building, Saint Paul, chairman of the award committee. Previous winners of the prize are Adolph Hanson, Faribault, 1927; Max Seham, Minneapolis, 1928, and Anderson C. Hilding, Duluth, 1929.

Dr. O. E. Locken, Crookston, presented the evening program of the Trail and Steele County Medical Society of North Dakota, May 1, at Northwood, North Dakota. He addressed the society on the subject of "Newer Phases in the Treatment of Heart Disease." Dr. Locken also gave the commencement address at the graduation exercises of the Nurses Training School of Trinity Hospital, Minot, North Dakota, May 12. Twenty-two nurses graduated from this new two hundred bed hospital.

A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION

Thank You, Mr. Rockne!

Knute Rockne is not a doctor. Probably, being one of the more illustrious and resourceful of famous football coaches, he doesn't even owe any doctors.

But here is his opinion of the profession reprinted from one of the popular Rockne columns called "Campus Comment" in the daily papers. It is of interest because Mr. Rockne is Mr. Rockne—because, as football coach, he has had some intimate dealings with doctors, and because he represents the more enlightened personages among the laity whose observations are worth something.

Perhaps Mr. Rockne's paragraphs will also come to the attention of certain popular magazines that have been occasionally given to airing other opinions on the subject of physicians. Mr. Rockne says:

"John Mohardt, one of my old halfbacks who used to team in the backfield with George Gipp, Paul Castner and Norm Barry back in 1920, is at Rochester. In another six months he will have finished his three year fellowship.

"John went four years to Notre Dame to get a B.S. degree; four years to Northwestern to receive an M.D., has spent two years in a hospital as an interne and then three years as a fellow in the clinic. Thirteen years of study since leaving high school before he feels he is ready.

"John will be 32 by the time he begins to be productive and the chances are that even then his earnings for the first few years will be rather slim.

"A terrific training for a young man. No other profession is nearly so exacting. I have been wondering what makes young men want to go into the practice of medicine with all its grief, endless hours, long preparation and what-not. It has been my observation that the good doctors have a sort of spark in their eyes, whereas many other professions interest men from the standpoint of monetary reward, easy livelihood, soft berth, prestige, or a stepping stone to something else.

"This can never be said of medicine. Medicine apparently is all-absorbing and occupies all of a man's wakeful moments and even some of the others.

"I have tried to analyze some successful doctors and I find that all of them have personality, ability, honesty, capacity for work, a burning zeal toward perfection in his chosen specialty, and intense responsibility regarding the human lives he is taking care of."

Results!

The improved state of mal-practice legislation in Minnesota, brought about largely through the efforts of the Minnesota State Medical Association, is showing very practical results to the physician.

A reduction of seven dollars in physician's mal-practice premium has just been announced by the Aetna Life Insurance Company, effective May 1, 1930.

For coverage of $10,000 to $30,000, the premium is now $21, instead of $28. This is the charge previously made for half the coverage.

Glenn Frank's Great Doctor

The great doctor must know almost as much about the social order as the sociologist. This is necessary because the varied forces—political, social, economic, industrial, educational, religious—that march across a nation, making its mind or marring its spirit, register their effects in the lives of the doctor's patients. The more the doctor knows about these forces that make the atmosphere in which men's minds and bodies live, the more intelligently can he trace effects to their causes, and the more wisely can he counsel his patients.

The great doctor must know almost as much about the mind as the psychologist. This is necessary because even the most materialistic scientist admits that there is a subtle relationship between mind and body that the doctor of the body dare not overlook, for when he does overlook this relationship a thousand quacks rush in to capitalize his oversight.

The great doctor must know as much about the subtle art of counselling as the priest.

The great doctor must refuse to be party to the ironic paradox of commercializing a profession just when the professionalization of commerce begins to dawn.

The great doctor must decline to tear his specialism out of the living texture of the whole medical fabric. He will not allow the noble science of surgery, for instance, to degenerate into a merely higher carpentry.

And, finally, the great doctor must be able to distinguish between Hippocratic ethics and hypocritic etiquette in matters professional.—*Glenn Frank, President, The University of Wisconsin, in Surgery, Gynecology and Obstetrics.*

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MINNESOTA STATE MEDICAL ASSOCIATION

Dr. W. T. Longcope, Professor of Medicine, Johns Hopkins, Baltimore, who is to address the Minnesota State Medical Association at the Annual Meeting in Duluth.

PROGRAM

62nd Annual Meeting
MINNESOTA STATE MEDICAL ASSOCIATION
Sunday, July 13, 1930, 6:30 P. M.
Meeting of the Council
English Room, Hotel Duluth
Monday, July 14, 1930, 2 P. M.
Meeting of the House of Delegates
English Room, Hotel Duluth
Registration and Meeting Headquarters—Duluth Hotel

Monday Morning—July 14—8:30 A. M.
Ball Room, Hotel Duluth

PRESIDING OFFICERS

Section on Medicine

F. A. Willius, M.D.....Rochester
Edgar T. Herrmann, M.D.....Saint Paul

Section on Surgery

J. M. Hayes, M.D.....Minneapolis
W. N. Graves, M.D.....Duluth

SYMPOSIUM ON TRAUMATIC SURGERY

Health Education
F. H. Magney.....Duluth

Wounds of the Chest *(lantern slides)*
B. F. Davis.....Duluth

Costochondral Graft for the Repair of Skull Defects *(lantern slides)*
A. M. Hanson.....Faribault

Head Injuries *(lantern slides)*
Wm. McK. Craig.....Rochester

Reduction of Compression Fractures of the Vertebra *(lantern slides)*
E. T. Evans.....Minneapolis

Treatment of Fracture of Hip—Whitman Method *(lantern slides)*
Emil Geist.....Minneapolis

Fractures of the Lower End of Tibia and Fibula *(lantern slides)*
V. P. Hauser.....Saint Paul

The Treatment of Tetanus and Gas Gangrene *(lantern slides)*
M. H. Manson.....Minneapolis

Acute Traumatic Surgery of the Abdomen
Karl Meyer.....Chicago
Associate Professor of Surgery, Northwestern University; Medical Superintendent, Cook County Hospital.

Address: Fractures *(moving picture demonstration)*
Primarius Lorenz Boehler.....Vienna
Chief Surgeon Director, Vienna Accident Hospital.

Monday Afternoon—July 14

The Treatment of Neurological Changes in Pernicious Anemia
W. T. Longcope.....Baltimore
Professor of Medicine, Johns Hopkins.

Address: Treatment of Nephritis
Franz B. Volhard..Frankfort-on-the-Main, Germany
Professor Internal Medicine and Director of City Hospital.

SYMPOSIUM ON IMMUNOLOGY

Poliomyelitis and Measles
C. A. Stewart.....Minneapolis

Diphtheria and Scarlet Fever *(lantern slides)*
W. Ray Shannon.....Saint Paul

Cerebro-Spinal Meningitis *(lantern slides)*
Carl O. Kohlbry.....Duluth

Pneumonia
E. P. Reiman.....Buffalo

The Problem of Allergy
W. P. Larson.....Minneapolis

OUR STATE INSTITUTIONS

Feeble Minded, Blind and Deaf
J. M. Murdoch.....Faribault

Tuberculosis
Arnold S. Anderson.....Saint Paul

Epileptic Colony
D. E. McBroom.....Cambridge

University Hospital *(lantern slides)*
Mr. Paul Fesler.....Minneapolis

Gillette State Hospital *(moving picture demonstration)*
C. C. Chatterton.....Saint Paul

Insane
A. F. Kilbourne.....Rochester

Monday Evening—July 14—7:30 P. M.
Ball Room, Hotel Duluth

MEDICAL ECONOMICS MEETING

E. A. Meyerding, *Chairman*

THE ECONOMIC TREND OF MEDICINE

The United States Veterans' Bureau, Its Place
N. S. MacDonald.....Minneapolis
United States Veterans' Bureau.

The Increasing Importance of the Medical Reserve
Col. George A. Skinner, M.C.U.S.A.....Omaha
Surgeon, Seventh Corps Area.

The Place of the Local Hospital
Mr. Paul Fesler.....Minneapolis
Superintendent, University Hospital.
The Doctor's Wife
Mrs. J. D. Lyon.....Minneapolis
President, Women's Auxiliary, Minnesota State Medical Association.
The Place of the Local Medical Society
Mr. Wm. J. Burns.....Detroit
Executive Secretary, Wayne County Medical Society.
In Wisconsin
Mr. J. G. Crownhart.....Madison
Secretary, Wisconsin State Medical Society.
In Middle West
John H. Peck.....Des Moines
President, Iowa State Medical Society.
What Is It?
Olin West.....Chicago
Secretary, American Medical Association.

Tuesday Morning—July 15—8:30 A. M.
Ball Room, Hotel Duluth

SYMPOSIUM ON EARLY DIAGNOSIS AND TREATMENT OF MALIGNANCY

Stomach *(lantern slides)*
Leo G. Rigler.....Minneapolis
Mouth and Lip *(lantern slides)*
F. A. Figi.....Rochester
Uterus
W. A. Coventry.....Duluth
Colon *(lantern slides)*
F. W. Rankin.....Rochester
Rectum
A. C. Strachauer.....Minneapolis
Breast *(lantern slides)*
O. J. Campbell.....Minneapolis
Urogenital Tract *(lantern slides)*
Walter Walters.....Rochester
Discussion
W. J. Mayo.....Rochester

Evulsion of the Phrenic Nerve for Pulmonary Tuberculosis *(lantern slides)*
Everett K. Geer.....Saint Paul
Some Clinical Features of Chronic Pulmonary Fibrosis *(lantern slides)*
A. T. Laird.....Nopeming
Acute Appendicitis—Causes of Death
A. L. McDonald.....Duluth
Intra-Abdominal Abscess *(lantern slides)*
P. E. Stangl.....Saint Cloud
Cinematograph Demonstration of Living Tissue Cells Growing in Vitro *(Canti)*

Tuesday Afternoon—July 15

SYMPOSIUM ON RHEUMATIC FEVER

Bacteriologic Studies *(lantern slides)*
B. J. Clawson.....Minneapolis
In Childhood
H. F. Helmholz.....Rochester
Carditis
Max Hoffman.....Saint Paul
Visceral Manifestations *(lantern slides)*
E. L. Gardner.....Minneapolis
Non-Articular Forms
Harry Oerting.....Saint Paul
Special Consideration of Etiologic Factors
Ralph Kinsella.....Saint Louis
Professor of Internal Medicine, St. Louis University.

Extra-Uterine Pregnancy
J. C. Masson.....Rochester
The Economic Importance of Squint in Children and Its Effect in After Years *(lantern slides)*
F. N. Knapp.....Duluth
Vaginal Hernia with Report of Two Cases Operated *(lantern slides)*
E. K. Green and L. K. Buzzelle.....Minneapolis
Further Results of the Treatment of Pernicious Anemia with Swine Stomach *(lantern slides)*

President-Elect.
The State Association
S. H. Boyer, President.....Duluth
The President-Elect.
Dancing

WOMEN'S AUXILIARY OF THE MINNESOTA STATE MEDICAL ASSOCIATION
Monday, July 14

3:00—
Meeting of the State Executive Board.
Home of Dr. and Mrs. Ben. F. Davis, 2317 Woodland Ave.
3:00—
Boulevard drive leaving the Hotel Duluth for the Garden Party Tea.
4:00-6:00—
Garden Party Tea.
Home of Dr. and Mrs. Ben. F. Davis, 2317 Woodland Ave.
7:30—
Medical Economics Meeting.
Ball Room, Hotel Duluth.

Tuesday, July 15

10:00 A. M.—
Annual Meeting.
English Room, Hotel Duluth
Address
S. H. Boyer, President.....Duluth
The Women's Auxiliary and the Committee on Public Health Education
George Earl.....Saint Paul
The Importance of the Women's Auxiliary
Ralph Knight.....Minneapolis
1:00 P. M.—Business Meeting.
Luncheon and Program—Northland Country Club.
Cars will leave the main entrance of the Hotel Duluth at 12:30 P. M.
Toastmistress, Mrs. James Blake, Hopkins
President, Women's Auxiliary of the Hennepin County Medical Society
Responses
By the Presidents of the Component Auxiliaries
Heart
C. N. Hensel.....Saint Paul
Immunology
H. F. Helmholz.....Rochester
6:30 P. M.—Annual Banquet
Ball Room, Hotel Duluth.

OUR GUESTS

Primarius Lorenz Boehler.....Vienna
Prof. Franz Volhard.....Frankfort-on-the-Main
W. T. Longcope.....Baltimore
E. P. Reiman.....Buffalo
Mr. Wm. J. Burns.....Detroit
E. C. Davidson.....Detroit
Mr. J. G. Crownhart.....Madison
Arnold S. Jackson.....Madison
Ralph Kinsella.....St. Louis
Karl Meyer.....Chicago
John H. Peck.....Des Moines
George A. Skinner.....Omaha
Olin West.....Chicago

THE SYMPOSIUM ON THE KIDNEY IN HEALTH AND DISEASE

Since the preliminary program was issued the number of contributors to the Symposium has materially increased. Thus Prof. I. Snapper is coming from Amsterdam, Dr. J. Gamble from Boston, Dr. Jonas Friedenwald from Baltimore, etc. It will be possible to give a presentation of the following topics.

The anatomy of the kidney will be presented in a way which might be considered characteristic of the present-day trend in American anatomy. The physiology of the kidney will be treated with considerable fullness and with close correlation between form and function.

The chemical processes taking place in the kidney usually do not receive much attention but will here be given separate consideration. The clinical ways of testing kidney function will be discussed in detail, particularly the new urea and creatinine tests.

The clinical aspects of Bright's disease will be presented at length in a series of clinics, for which several doctors outside the University clinics have kindly

contributed valuable material. The pathological changes occurring in the kidneys will be described and the nature of the pathological processes discussed. The degree of correlation existing between anatomical lesions and the clinical pictures of Bright's disease will provide the topic for a round table discussion. Borderline cases between harmless albuminuria and Bright's disease will be presented and discussed. Albuminuria itself will be discussed both as to its chemical nature and in regard to its effect upon the blood proteins. The newer clinical tests for albumin will be demonstrated and evaluated.

The edema problem will be treated at some length. The same will be the case with the topic of uremia. The treatment of the convulsive type of uremia will be given special consideration. The eye changes in Bright's disease will be diagnosed and discussed at considerable length both as to their diagnostic and prognostic significance. Special discussion will be given to the chapter of hypertension. The general treatment of the diseases of the kidney will be outlined and the nature of the effect and the specific use of diuretics will be presented in detail.

The number of round table discussions has been increased so as to give every opportunity for the presentation of different points of views. A number of medical clinics in U. S. A. and Canada will be represented at the round tables and their experiences will be communicated.

An exhibition of older works dealing with the kidney has been arranged in the University Library by Dr. S. P. Miller of the Department of Anatomy.

A report containing the essential material presented during the Symposium will be published as an independent volume as soon as possible after the Symposium.

MINNESOTA SOCIETY OF INTERNAL MEDICINE

Duluth entertained the membership of the Minnesota Society of Internal Medicine for its semi-annual meeting Monday, May 26. Out of a membership of about fifty over 80 per cent were in attendance. The program was a very intensive one, made up of twenty-one presentations, all by members.

At a banquet session in the evening Dr. Anderson Hilding (formerly of Duluth, now of Rochester, Minnesota) presented his prize winning thesis dealing with "The Common Cold."

Dr. E. L. Tuohy presided at the meeting and banquet.

DAKOTA COUNTY MEDICAL SOCIETY

Preparations for organization of a Dakota County Medical Society were begun by eight Dakota County physicians at Hastings, Monday, June 9.

Dr. E. A. Meyerding, secretary of the State Association, and Dr. F. J. Savage, councilor of the district, were present to assist in organization. They will present application for a charter for the new society to the House of Delegates at the annual state meeting in Duluth, July 14, 15 and 16.

With the organization of the Dakota County Society, only one county, Lake of the Woods, still remains unorganized or unaffiliated with some county medical organization in the entire state of Minnesota.

The Dakota County signers of the petition for a charter are L. D. and L. R. Peck, H. A. Fasbender, R. C. Radabaugh, Hastings; T. J. Gaffney, Lakeville; J. A. Sanford and G. A. Walter, Farmington, and W. T. Hagerty, Cannon Falls.

SCOTT-CARVER COUNTY MEDICAL SOCIETY

Scott-Carver County Medical Society officers elected at the annual meeting of the Society at Shakopee, June 10, for 1931 are: Dr. M. B. Hebeisen, president; Dr. W. S. Emmerson, vice president; Dr. C. F. Cervenka, secretary and treasurer; Dr. Fred C. Westerman, delegate; Dr. B. H. Simon, alternate, and Dr. M. B. Hebeisen, censor.

Dr. Frederic Foley, St. Paul, addressed the Scott-Carver meeting on various types of bladder neck obstruction and Dr. C. N. Hensel, St. Paul, talked on the heart. The July meeting of the Society will be held at Watertown by invitation of Dr. H. A. Halgren.

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 10:15 o'clock every Wednesday morning over station WCCO, Minneapolis and St. Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of July will be as follows:

July 2—Vacation Time
July 9—Growth in Childhood
July 16—Cause of Hernia
July 23—Facial Neuralgia
July 30—Common Foot Disorders

RIVAL PROPHYLACTICS IN DIPHTHERIA

The early success with toxin-antitoxin in this country has given to it almost exclusive use in prophylaxis. There are, however, other effective ways of reducing the toxicity of diphtheria toxin besides partial neutralization with antitoxic serum. The products of these newer methods have been extensively used in Canada and in Europe. In the schools of Milwaukee from 1925 to 1928 the respective percentages of immunity achieved by the use of toxin-antitoxin were 85, 62, 75 and 69. With diphtheria toxoid better results were obtained, only 2 out of 128 giving positive Schick tests after treatment. Another claim in favor of diphtheria toxoid is that it does not result in sensitization to horse serum. However, it is not likely that toxin-antitoxin produces any noticeable sensitization; further, the toxin-antitoxin may be prepared with goat or sheep serum. Diphtheria toxoid would seem to be at least as valuable as diphtheria toxin-antitoxin mixture and in the pre-school child is probably to be preferred. (Jour. A. M. A., May 24, 1930, p. 1708.)

OBITUARY

Louis Leypoldt Moench

1875-1930

Dr. L. L. Moench, well known physician of Waterville, Minnesota, met death Monday afternoon, June 2, 1930, when a deer rifle which he was taking from his car was accidentally discharged. He was instantly killed when the bullet entered his body under the right arm and came out over his heart. The rifle was a 30-30 Winchester which had been purchased for the purpose of deer hunting. Death was instantaneous. The deputy coroner, Dr. Kolars, of Le Sueur Center, was called and gave his verdict that the shooting was accidental.

Dr. Moench, born Dec. 6, 1875, received his medical training at the Eclectic Medical Institute, now the Eclectic Medical College in Cincinnati, where he was graduated in 1903. He practiced at Monteith, Iowa, and at Kilkenny before moving to Waterville, where he had practiced for the past sixteen years.

Dr. Moench is survived by his wife and two sons, George 21, and Hubert 17.

Benjamin M. Randall

1858-1930

Dr. Benjamin M. Randall, a practicing physician at Graceville, Minnesota, for many years, died at his home May 24, 1930. Death was due to arteriosclerosis and cerebral hemorrhage.

Dr. B. M. Randall, son of Major B. H. Randall, was born at Fort Ridgely, Minnesota, on June 7, 1858. A few years later following the outbreak of the Sioux Indians in that region he moved with his parents to St. Peter, where he received his early education. He was graduated from Rush Medical College in 1883. After practicing a year in Graceville he left for New Ulm, but returned to Graceville the following year and has practiced here since that time. He is survived by his widow, Lenora Fallon Randall, four daughters, the Misses Willa and Esther Randall and Mrs. M. J. Goblirsch of Graceville and Mrs. F. A. Cummings of Minneapolis, and two sisters, Mrs. Leroy Foster and Miss Froelie Randall of Opalocka, Florida.

From the days of his coming to Graceville Dr. Randall has ever been a valued participant in the social life of the vicinity. He was a member of the Court of Honor, the Hibernian Society, and the Knights of Columbus as well as of numerous other groups organized from time to time for individual or civic uplift.

In the formation and development of the Old Settlers Association he had the keenest interest, ably assisting as he could with his vast fund of accurate historical information covering early Minnesota. Many have been the gatherings made incomparably richer by the gems of thought and sparkling wit reflected from his wealth of cultured background.

To the many now scattered associates of his early years in Graceville the very name of Dr. Randall recalls a host of poignant memories, and no mere words can serve to estimate their sense of appreciation of all that he has meant to them. A friend of later days makes mention of a never-to-be-forgotten period in his career when failure to be accepted among those enlisting for War service left him the sole responsibility of administering medical aid through a large territory during the ravaging "flu" epidemic of 1918, a work of sacrifice and heroism accomplished under almost impossible conditions. Thus, those who have come to know him in more recent times as well have not failed to be impressed by the unusual quality of his devotion to his chosen field, a profession privileged and made nobler still in having him as a symbol of its loftiest ideals.

George Ellsworth Chamberlain

1864-1930

Dr. George Ellsworth Chamberlain, well-known physician and surgeon of Aberdeen, Washington, and a practitioner for several years in Minnesota, died April 13, on the anniversary of the day in 1893 when he was graduated from the College of Physicians and Surgeons of Chicago, the medical department of the University of Illinois. His death came in his sleep and although he was stricken with a cerebral hemorrhage last May, his condition has been no more serious than before and his passing was a surprise to family and friends.

He is survived by his wife and two children, Samuel V. Chamberlain of Paris, France, and a daughter, Mrs. Walter Wiebenson, of Sausalito, California.

Dr. Chamberlain was born in Indiana July 8, 1864. From his earliest years he evinced a strong desire to become a physician and worked throughout his early years to attain that desire. Colonial ancestry on both sides of his family made him strongly patriotic. His grandparents were among the early settlers in Boone county, Kentucky, being located there at the time of the Revolution.

After his graduation with high honors from the medical college, he practiced in Wells, Minnesota, for two years. He located at Waterville, Minnesota, where he practiced his profession until 1902, later settling at Bismarck, N. D. He was married July 3, 1892, to Miss Cora Lee Summers at Richmond, Wisconsin.

Dr. and Mrs. Chamberlain moved to Aberdeen March 5, 1905, and have since resided in that city. He founded the Aberdeen General Hospital about twenty years ago and was its president until March 12, 1928. He was the first physician in the city to become a Fellow of the American College of Physicians and Surgeons, an honor which was very dear to his heart. He was a member of the Elks and of the Masons. He was a kindly, lovable man, understanding of young and old alike and ever faithful to his duty and ready to give of his sympathy and time.

CONSULTATION BUREAU

WM. A. O'BRIEN, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question.*—A patient of mine has undulant fever according to the laboratories of the State Department of Health. The fever persists. I understand that you have a case at the University Hospital now. What treatment have you worked out? I would be very glad to try anything that is promising.

   Answer.—As far as we have been able to find, no specific treatment exists for undulant fever. The treatment is expectant. If the patient is losing weight, it is advisable to put him on a high caloric diet. Bed rest may be necessary because of fatigue and analgesics for pain. As a general rule patients with undulant fever feel fairly well and are able to do a limited amount of work. A vaccine is being tried at the present time, but the results are variable, and the reactions are said to be severe.

2. *Question.*—I would like to have a little advice on treating a case of gingivitis due to actinomycosis. The case is of about two years' duration. Diagnosis was made by the sulphur granules. At two different times these were placed under the microscope, and a typical filament formation was seen. The gums are involved on both the buccal and lingual surfaces along the incisors and cuspids of both the upper and lower jaws. During the past month I have had the patient using potassium iodide internally and tincture of iodine locally three times a week. The tincture of iodine was discontinued two weeks ago because it irritated the gums too much. I have just started the use of ultraviolet light on this patient, but have not had time yet to observe its effects. Any suggestions you have to offer in the treatment of this case will be appreciated.

   Answer.—Your patient probably has pyorrhea alveolaris. Fungi belonging to the actinomycosis group are found in this disease. They are not the pathogenic organism responsible for the disease as we know it in man and animal. The first essential in the treatment of pyorrhea is to avoid excessive local treatment. The mouth should be thoroughly cleansed daily and the gums massaged. A dentist should examine the mouth very carefully for evidence of malocclusion. The trauma incident to malocclusion often keeps up the trouble in the gums. If this can be corrected the mouth will often clear up without any further treatment.

3. *Question.*—A patient recently presented himself at the clinic for diagnosis giving a history of having passed large quantities of urine for several years and of consuming large quantities of water. The patient is ten years old, a male, underdeveloped and undernourished. The specific gravity of the urine is practically 1 and of very light color. A provisional diagnosis of diabetes insipidus has been made. I would like very much to know of any recent development in the treatment of this disease and would appreciate any suggestions that you may have to offer.

   Answer.—Pituitrin materially relieves the unpleasant symptoms of diabetes insipidus when given in daily injections of amounts determined by the tolerance of the patient. Such treatment is not curative, however. I would advise you to start out with a daily injection of pituitrin, graduating the dose according to the relief of symptoms. If the injections in the arm became painful, it may be used on pledgets of cotton placed in the nose. The urine should be carefully followed for any evidence of sugar which might appear at a later date. It would also be advisable to correct any disturbing emotional factors which may be present in the child's environment. Sometimes diabetes insipidus is precipitated by a fright or scare and relief of symptoms may be obtained in part by correcting environmental factors.

4. *Question.*—I have a case of headache in a young man, age 24, that has presented no little difficulty in diagnosis. The history follows: The patient had been working on a farm for several months. On Monday, June 2, he left the farm and started home. While on the train he began to complain of a throbbing frontal headache. This continued until Wednesday night, June 4, when I first saw him. The headache was extremely severe, but was relieved after an hour by ⅓ grain pantopon. Physical examination revealed essentially nothing abnormal; pulse 68, temperature 98.4, blood pressure 130/78, urine normal. There was a considerable amount of mucopurulent discharge from the nose which led to a tentative diagnosis of frontal sinusitis. On June 5, the patient felt well and was up and about all day, but about 8 P. M. he was suddenly taken again with very severe headache. He was crazy with pain, crying out in agony, pounding his head, and unable to lie still for more than a few seconds at a time. I stayed with him for several hours, and after he had had one grain of pantopon and 1/150 grain of hyoscine hydrobromide, he was slightly relieved. About 2:30 A. M. he had a generalized tonic convulsion (which I did not observe) that lasted for about five minutes. After that he dozed until morning. On June 6, he was admitted to the hospital. An ophthalmologist reported no error of vision and normal fundi. *X*-ray examination showed no pathology in the sinuses. A lateral stereo of the head was negative except for indefinite outline of the posterior clinoid process of the sella turcica. Spinal puncture gave a clear spinal fluid with cell count of 10. Spinal pressure was 9 mm. of mercury, and after removal of 15 c.c. of fluid the pressure was 6. Spinal puncture gave no relief from headache. Blood and spinal fluid Wassermanns negative. Leukocyte count 8,700. Patient remained in hospital until June 10. During his stay, the headache gradually subsided with with occasional doses of morphine and hyoscine. Since his discharge he has felt well. There is nothing in the family history or in the past history which throws any light on the case.

   Answer.—The headache does not resemble the usual attack of migraine. You have apparently ruled out sinus infection. Epilepsy does not

(Continued on Page 514)

MISCELLANEOUS

THE SCOPE AND AIM OF THE COMMITTEE ON THE COST OF MEDICAL CARE

At the spring meeting of the Committee on the Cost of Medical Care in Washington, May 2 and 3, 1930, a special committee of private practitioners was appointed to consider the relation of the committee to the private practitioners of the country. This committee, composed of the undersigned members, now submits the following statement for the information of these practitioners on the scope and aim of the committee's work.

It was clearly recognized by all present at the spring meeting that the committee has undertaken a program of studies which in its scope goes far beyond that part of the cost of medical care which physicians provide. The expense of several other kinds of service now looms large in the total cost of many illnesses. In addition, special emphasis was given at the meeting to the question of the adequacy of the various services available in a community. Finally, the committee adopted a statement of three fundamental principles proposed by the Chairman, which should go a long way toward reassuring those who have been apprehensive regarding the nature of the committee's ultimate recommendations.

I.

The committee is interested in far more than the physician's bill, which, in many instances, is considerably less than half the total cost of illness. Hospital care, nursing, dentistry, laboratory examinations and medicines often involve considerable expense, as is clearly shown by several of the committee's studies which are now being completed or have already been reported upon. In one middlewestern county recently surveyed, the expenditures for various kinds of medicines constituted over one-third of the total expense for medical care, and were 20 per cent greater than the costs of physicians' services. It is also becoming apparent that a great deal of money is being spent for useless medicines and for various irregular forms of treatment which do the patient no good or which may result in positive harm.

In order to indicate clearly the broad scope of the committee's work, it was decided at the spring meeting to make a slight change in its name. The word "cost" is to be changed to "costs." The complete name of the committee, with subtitle, will henceforth be "The Committee on the Costs of Medical Care—Organized to Study the Economic Aspects of the Prevention and the Care of Sickness, including the Adequacy, Availability and Compensation of the Persons and Agencies Concerned."

One vital problem before this committee, declared a prominent physician member, at the recent meeting, is the determination of what is reasonably adequate care. In many cases of obscure disorders and serious illness, expensive facilities are essential. Presumably, there must be available in the community well trained general practitioners, certain specialists, dentists, nurses, hospitals and health agencies—trained and well equipped to do their part in providing all the care that the individual may need. A plan of the executive committee, to conduct a study to determine standards of adequate medical care, under the general direction of some well-known competent physician and with the assistance of a committee of fifteen or twenty other physicians, was heartily endorsed at the meeting of the general committee.

The aim of the committee is to study the problem described by Dr. Olin West, the Secretary of the American Medical Association, as the one great outstanding problem before the medical profession today. This, he says, is that involved in "the delivery of adequate, scientific medical care to all the people, rich and poor, at a cost which can be reasonably met by them in their respective stations in life." The committee is endeavoring to establish a foundation of facts which have an important bearing upon this problem. On the basis of these facts, it will propose recommendations for the provision of adequate and efficient therapeutic and preventive service for all the people at a reasonable cost to the individual, which, at the same time, will provide physicians, dentists, nurses, hospitals and other agents assurance of adequate return. This is not a new statement of aim. Recent discussion, however, has given new emphasis to certain aspects of it. There are important items in the cost of sickness other than the physician's bill; and the adequacy of the service provided must be considered. The program of studies is a comprehensive one. It deals with questions of supply, demand, distribution and costs of all kinds of services, both preventive and curative; the relation of these costs to other expenses; the return accruing to the practitioners and various agents furnishing medical services; and especially will it seek to determine what standards of adequacy may reasonably be expected.

II.

Dr. Ray Lyman Wilbur, Chairman of the committee, proposed at the meeting May 2 a statement of three fundamental principles for the consideration of the committee. This statement was referred to each of four subcommittees which held sessions during the two-day meeting. The entire committee, at its last session, May 3, adopted with a few verbal changes the three principles. These will be of special interest to the physicians and dentists. They follow:

1. *The personal relation between physician and patient must be preserved in any effective system of medical service.*

Medical service is and doubtless, by its very nature, must remain a distinctly personal service. Even in this age of standardized commodities for the table, ready-to-wear clothing, and interchangeable spare parts for all types of machines, there has been no plan suggested for the reduction of medical diagnosis and treatment to basic units which can be ordered from travelling salesmen or acquired through correspondence courses. The physician must see his patient and see him, in many cases, over an extended period of time if the diagnosis and treatment are to achieve the greatest

possible accuracy and efficiency. There is no substitute for personal observation.

Man is not a standardized machine and each individual reacts to the conditions of life in a manner in some respects unique. In the treatment of disease, this individual variation is a factor of great significance and can receive due consideration only when the practitioner has known the patient for a considerable time and maintains a personal relation with the patient.

2. *The concept of medical service of the community should include a systematic and intensive use of preventive measures in private practice and effective support of preventive measures in public health work.*

The cost of adequate curative treatment is now high and may continue to increase as expensive procedures resulting from scientific progress become more widely used. Sickness, in addition, involves other personal and social costs, some of which cannot be measured in monetary terms.

The outstanding achievements in scientific medicine have been made in the preventive rather than the curative field. Knowledge now available for the control of malaria, tuberculosis, smallpox, diphtheria, pellagra, typhoid fever, hookworm disease, and goiter, if effectively applied, would make unnecessary a considerable proportion of the present expense for the cure of sickness.

3. *The medical service of a community should include the necessary facilities for adequate diagnosis and treatment.*

From the standpoint of effective diagnosis, many diseases, such as tuberculosis, cannot be recognized promptly in their early stages without the aid of elaborate technical equipment. From the standpoint of adequate therapy, if the best of modern technic is not immediately available, complete cures are either delayed or rendered impossible of attainment. To cite a specific illustration of the improvement of modern therapeutic procedures over those of ten years ago, the time required for treatment of fractures of the hip, and the percentage of permanent invalidity resulting from that injury have each been reduced by more than half.

We cannot be content with anything except the best possible service that modern science can provide and it is therefore imperative that modern scientific equipment for the diagnosis and treatment of disease be available to the practitioners of medicine in every community.

Special Committee of Private Practitioners.

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

THOMAS A. PEPPARD,
MEDICAL ARTS BLDG., MINNEAPOLIS

THE CLINICAL SYNDROME OF HYPERPARATHYROIDISM: David P. Barr, M.D., and Harold A. Bulger, M.D. (Amer. Jour. of Med. Sci., April, 1930, p. 449). The authors review the literature relating to the experimental results obtained by the injection of excessive amounts of parathormone. The essential characteristic is a rapidly developing hypercalcemia. Symptomatically there is restlessness, respiratory distress, vomiting, diarrhea, hematemesis, melena, collapse and death. There is usually hematuria, and in the fatal cases the kidneys cease to function about the time that the maximum value of hypercalcemia is obtained. During the terminal period, the phosphates and the nonprotein nitrogen of the blood rise rapidly. They have collected from the literature and report in brief twenty-nine cases of parathyroid tumors. (These were summarized from the report of Hoffheinz.) In addition 74 examples of pathologically enlarged parathyroid glands included malignant and benign tumors as well as simple hyperplasia.

Conditions associated with enlargement of the parathyroid are nephritis, kidney stone, pituitary tumor, acromegaly, but most particularly diseases of the bones, and especially generalized osteitis fibrosa.

Of interest is the finding of metastatic calcification in the lungs, stomach, and kidneys.

Their own case reports, numbering five, include four female and one male, ages from 11 to 56. The first case is reported in great detail, and includes the operative removal of a parathyroid tumor. This surgical procedure caused a severe tetany, produced a hypocalcemia and a strongly positive calcium balance, and hyperphosphatemia. It prevented advance in the bone disease, and resulted in some subjective and objective improvement.

The second patient was also operated upon, and following operation the serum calcium fell below the normal level, and minor subjective symptoms of tetany developed. This patient was definitely improved.

The third patient died after some months.

(Autopsy and microscopic findings in cases four and

five.) The onset of the disease had occurred in childhood. The roentgen ray appearance of the bone was typical of osteitis fibrosa cystica. There was no evidence of hyperparathyroidism. The values for serum calcium were within normal limits.

Some others have found high values for blood calcium in the following conditions: abnormal ingestion of calcium, joint diseases, polycythemia, nephritis, multiple myeloma, carcinomatous metastases in bone, and osteitis fibrosa.

In summary: the symptoms of clinical hyperparathyroidism are similar to those produced by the experimental injection of excessive amounts of parathormone. They include:

1. Hypotonia.
2. Diminished electrical excitability of muscles.
3. Decalcification of bones.
4. Hypercalcemia.
5. Abnormal excretion of calcium in the urine.
6. Nephrolithiasis.
7. Hypophosphatemia.

Hypercalcemia is the most significant clinical sign. Determinations of calcium and phosphate content of the blood serum should be made in all cases of generalized bone disease, not only as a matter of interest, but because of their therapeutic indications.

ROENTGENOLOGY

SUPERVISORS

LEO G. RIGLER

UNIVERSITY HOSPITAL, MINNEAPOLIS

A. U. DESJARDINS

MAYO CLINIC, ROCHESTER

ROENTGEN STUDIES ON THE APPEARANCE OF SPINAL TUBERCULOSIS IN AN EARLY STAGE: M. Sgalitzer (Fort. a. d. Geb. d. Rönt., V. 40, p. 761., Nov., 1929). Sgalitzer presents, in a well illustrated article, a series of cases to demonstrate the factors in the roentgen diagnosis of early tuberculous spondylitis. The most important of his findings are:

1. Paravertebral abscess is present in two-thirds of the cases, may be recognized much earlier in the roentgenogram than clinically, and, when present, is almost pathognomonic of spinal tuberculosis.

2. Paravertebral abscess may be the only roentgen evidence of this condition. This may indicate either a very early tuberculosis or a very benign type.

3. The size of the abscess bears no relationship to the extent of the tuberculosis.

4. A change in the normal curve of the spine, such as the presence of kyphosis of the cervical or lumbar vertebræ may be a very early sign of the disease.

5. We may occasionally see the tuberculous focus as a large or small area of destruction in the center of the vertebral body without any narrowing of the intervertebral disc.

6. Another type of case presents a slight narrowing of the anterior portions of a number of vertebral bodies with narrowing of the discs and possibly a large abscess.

7. Calcification may occur in the abscess and give distinct shadows.

8. Osteomyelitis may also give an abscess and presents the only difficulty in the roentgenologic differentiation. The history and other findings will usually rule it out.

9. There is a type of vertebral tuberculosis which is very benign and very chronic, and is often mistaken for "rheumatism." Many of these cases show large abscesses which serve to identify them even though no definite changes are visible in the vertebræ themselves.

Leo G. Rigler, M.D.

FACTORS OF ERROR IN THE ROENTGENOLOGIC DIAGNOSIS OF DISEASES OF THE COLON: H. M. Weber, M.D. (Radiology, XIV, 5, May, 1930, p. 460). The accuracy of roentgenologic examination of diseases of the colon is very high. Thorough cleansing of the bowel is necessary for accurate diagnosis and to avoid errors due to apparent filling defects caused by fecal material, gas, and retained pockets of fluid in the colon. Palpation is done under roentgenoscopic control while the barium enema is being given. To assure complete filling of the cecum the enema should be permitted to pass through the ileocecal valve into the terminal ileum.

The filling defect or organic deformity of the luminal contours is by far the most common roentgenologic sign of colonic disease. Carcinoma, diverticulitis, tuberculosis, localized chronic ulcerative colitis, localized encroachment on the lumen of the bowel by extrinsic processes, organic inflammatory stricture and syphilis, named in the order of their frequency, manifest themselves by filling defects, constantly or occasionally. The filling defect of carcinoma is annular, polypoid or obstructing. Diverticulitis is generally found in the sigmoid colon and produces a spindle-shaped shadow with serrated contours and usually the extra-luminal pockets can be demonstrated. Both the attending spastic factor and the mural inflammatory infiltration combine to form the filling defect. Localized chronic ulcerative colitis resembles carcinoma and the differentiation is often difficult. Deformities due to extrinsic lesions may be caused by direct pressure on the colon or by spasticity due to inflammations in the immediate neighborhood. Organic stricture and syphilis of the colon are rare. Tuberculosis is generally found in the cecum and ascending colon and produces an irregular filling defect and a peculiar boggy consistence of the bowel. It is almost always associated with pulmonary tuberculosis.

Several films illustrate the conditions described.

PEDIATRICS

SUPERVISORS:
CHESTER A. STEWART,
MEDICAL ARTS BLDG., MINNEAPOLIS
ROY N. ANDREWS,
MANKATO CLINIC, MANKATO

IDIOPATHIC ANEMIA OF THE NEW-BORN INFANT: Wm. Morris Happ, M.D., Los Angeles (Arch. of Ped., March, 1930, Vol. XLVII, No. 3). Pediatric literature contains very meager information concerning idiopathic anemia of the new-born infant. By this term is meant an anemia occurring during the first few days of life for which there is no satisfactory etiologic factor. Only six cases of anemia in new-born infants have been reported.

The infant is born at term, the birth is normal. Pallor may be noted at birth or during the first few days of life with gradual increase. This pallor is the only striking symptom and leads to an examination of the blood. This shows an actively regenerating anemia with marked reduction in red cells and hemoglobin. The white cells are usually increased in number, the differential count is normal; myelocytes may be present and platelets are normal. Active regeneration is evidenced by nucleated red cells, polychromatophilia and increase in reticulated cells. The spleen is usually slightly enlarged, but there is no general glandular enlargement.

In one case, where the fragility of the red cells was tested, this was found increased. The cases which have not been treated have recovered during the first year. Those treated by blood transfusion have recovered more quickly.

The etiology is obscure. There is no conclusive evidence of a hemolytic nature of these anemias. They regenerate rapidly. Blood transfusion seems to offer a definite stimulus to hematopoietic activity. It is recommended as the treatment of choice, together with the administration of iron, in the form of inorganic iron, in broths and liver.

R. N. Andrews, M.D.

THE USE OF GELATIN AS A SUPPLEMENTARY FOOD IN THE INFANT'S DIETARY: Theo. O. Elterich, M.D., D. H. Boyd, M.D., and Andrew Neff, Ph.D., Pittsburgh (Arch. of Ped., May, 1930, Vol. XLVII, No. 5). Ruehrar and Friedenwald state that only recently has the real value of gelatin in the diet been more widely known. It is very useful in rendering milk mixtures more digestible, preventing both gastric and intestinal indigestion by preventing the large, hard curds. It is of value in infants who regurgitate or vomit their food, in diarrhea, particularly where there is putrefaction. It is useful where gas is formed, either in the stomach or the intestines, and in fermentative conditions in general. It is useful in preventing colic in some babies, and in the breast-fed may be given in solution just before feeding. In infants who are constipated and who have large, hard stools which do not adhere to the napkin, the addition of gelatin to the formula usually corrects the difficulty. It is of great value in celiac disease, not only in supplying additional much-needed food, but in correcting the accompanying indigestion. In malnutrition the addition of gelatin to the dietary is of great value, as it is in those who have lost weight through operations, fevers, or other illnesses.

Large amounts of gelatin may be administered to very small infants over fairly long periods of time without any apparent unfavorable consequences.

Contrary to previously reported studies, gelatin does not accelerate growth out of proportion to calories ingested. Gelatin acts like protein matter and gain in weight is in proportion to protein-carbohydrate ratio.

Our feeling would be that gelatin addition to formulæ produces results similar to those found when protein milk is added to formulæ, but it must be remembered that gelatin is an incomplete protein. On the other hand, the addition of gelatin to a formula of an older infant is less likely to be distasteful than would be the case with high acid formulæ.

One hundred calories of gelatin (four level tablespoonfuls of powdered gelatin) may be added to the day's formula without increasing the volume. This is an advantageous factor in cases where infants have a tendency to vomit, in cases where high cereal formulæ are necessary, or in cases where it is difficult to get infants to ingest normal quantities of food.

Gelatin may be a food factor in certain unusual allergic infants, where the ingestion of either breast or cow's milk cannot be tolerated.

CONSULTATION BUREAU

(Continued from Page 510)

start as a rule with so much pain. Was there any history of excessive exposure to the sun? Spontaneous subarachnoid hemorrhage should be considered. As a general rule spinal puncture reveals the nature of this disease. The fluid is either bloody or tinged a yellowish color. If you had done a Queckenstad test, that is, pressure on the jugulars with a spinal needle in position, you might have found a block which would explain the absence of bloody fluid. As a general rule this disease occurs in young people and has a fairly favorable prognosis. There is diffuse hemorrhage over the surface of the brain of probable unknown origin. Was there any history of trauma or drugs? Brain tumor should also be considered. In spite of the negative fundi, it would be advisable to do an estimation of the visual fields. It may be done without much difficulty, and in spite of the fact that the patient is now feeling better I would advise you to examine him again for any disturbance in his fields. This is especially valuable in tumors of the pituitary gland and may also be of diagnostic value in temporal and occipital tumors. As a last resort and after prolonged observation, a probable psychic origin for the headaches should be considered. It would be advisable for you to check the patient at frequent intervals with a thorough neurological examination and not to let him go because no definite diagnosis can be made.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

OBSTETRICS FOR NURSES. Charles B. Reed, M.D., F.A.C.S., Professor of Obstetrics, Northwestern University Medical School, Chief Obstetrician Wesley Memorial Hospital, Chicago, and Charlotte L. Gregory, R.N., B.S., M.D., Adjunct in Obstetrics Wesley Memorial Hospital, Clinical Assistant in Obstetrics Northwestern University Medical School, Chicago. 399 pages. Illus. Cloth $3.00. St. Louis: C. V. Mosby Company, 1930.

MINOR SURGERY. Arthur E. Hertzler, M.D., Chief Surgeon, Halstead Hospital, and Victor E. Chesky, M.D., Chief Resident Surgeon, Halstead Hospital, Halstead, Kansas. Second Edition. 602 pages. Illus. Cloth $10.00. St. Louis: C. V. Mosby Company, 1930.

PHYSIOLOGY AND BIOCHEMISTRY IN MODERN MEDICINE. J. J. R. Macleod, M.B., LL.D., D.Sc., F.R.S., Regius Professor of Physiology in the University of Aberdeen, Scotland; formerly Professor of Physiology in the University of Toronto, Canada, and in the Western Reserve University, Cleveland, Ohio. Sixth Edition. 1074 pages. Illus. Cloth $11.00. St. Louis: C. V. Mosby Company, 1930.

CERTIFIED MILK. Proceedings of the American Association of Medical Milk Commissions, Inc. 350 pages. Illus. Cloth. Brooklyn, N. Y.: American Association of Medical Milk Commissions, Inc.

ALIMENTARY ANAPHYLAXIS. Guy Laroche, Charles Richet Fils and Francois Saint-Girons, of Paris, France. Translated by Mildred P. Rowe and Albert H. Rowe. 139 pages. Cloth $2.00. Berkeley, Calif.: University of California Press.

CLINICAL FEATURES OF HEART DISEASE. Leroy Crummer, M.D., Emeritus Professor of Medicine, University of Nebraska. Introduction by Emanuel Libman, M.D., Professor of Clinical Medicine, Columbia University. Second Edition. 415 pages. Cloth $4.00. New York: Paul B. Hoeber, Inc.

ALLERGIC DISEASES—Their Diagnosis and Treatment. Ray M. Balyeat, M.A., M.D., F.A.C.P. Lecturer on Allergic Diseases in the University of Oklahoma Medical School; Consulting Physician to St. Anthony's Hospital and to State University Hospital, etc. 395 pages. Illus. Cloth, $5.00. Philadelphia: F. A. Davis Company, 1930.

MERCK'S INDEX. An encyclopedia for the chemist, pharmacist and physician. Fourth Edition. 585 pages. Rahway, N. J.: Merck & Co., Inc.

UTERINE TUMORS. Charles C. Norris, M.D., Professor of Gynecology and Obstetrics, University of Pennsylvania. Limp leather. Price, $3.00. 251 pages with 14 illustrations. New York: Harper & Brothers, 1930.

This small volume is one of a series of medical monographs published, and in preparation by Harpers.

The author stresses the importance of the uterus as a site for neoplasms whose course and share in the increasing cancer mortality may be definitely effected for the better by early diagnosis and careful treatment. The work is largely based upon material from the laboratory of the Hospital of the University of Pennsylvania, and this, coordinated with treatment and follow-up records, is the basis for the author's recommendations.

The Clark test for carcinoma of the fundus is stressed as a simple means for early diagnosis of that condition. "It is of great practical value, and although it lacks the accuracy obtained by curettage, it possesses the following advantages: it may be employed in the physician's office; it requires no special skill or histologic knowledge, or extensive armamentarium; it involves no loss of time." In this test a sound is inserted into the fundus; if a friable, vascular growth is encountered, withdrawal of the sound will be followed by a trickle of bright blood from the cervix.

There is a careful evaluation of results obtained by the use of surgery, radium, and x-ray treatments.

The book has seven chapters as follows: Cervical Polyps, Carcinoma and Other Malignant Tumors of the Cervix, Carcinoma of the Body of the Uterus, Myoma Uteri, Sarcoma and Allied Tumors of the Body of the Uterus, and Tumors of the Chorion.

E. C. HARTLEY, M.D.

INFANT NUTRITION. William McKim Marriott, B.S., M.D., Professor of Pediatrics, Washington University School of Medicine; Physician in Chief, St. Louis Children's Hospital, St. Louis. 375 pages. Illus. Cloth, $5.50. St. Louis: C. V. Mosby Company, 1930.

Very few outstanding pediatricians are able to resist the urge to write a book on advice to mothers, or a volume on infant feeding. Thus it was to be expected that W. McKim Marriott of St. Louis would produce a text of this type. His extensive training in physiochemistry has manifested itself in the very excellent chapter on anhydremia, acidosis and alkalosis. Otherwise it resembles closely the stereotyped book of its kind. It does, however, include many of the newer ideas in infant feeding, and omits repetition of obsolete theories and methods. The author's ambition to simplify the subject of infant feeding does not seem entirely realized, although in this respect he has achieved no less than his predecessors.

The writer demonstrates the tendency in pediatrics toward ample feeding, as opposed to the underfeeding so commonly practiced in the past. Thus, he advocates giving infants both breasts every four hours, instead of one breast at a feeding, as is so commonly advised; also, that infants require 2.5 to 3 ounces of breast milk per pound of body weight daily—a more generous allotment than formerly. He states similarly

that the caloric requirement of a normal infant is 115 calories per kilo. He stresses the necessity for feeding an undernourished infant on a basis of what it should weigh rather than on its actual weight. His suggestion that pasteurized milk is usually as satisfactory as certified milk, but that all milk for infant feeding should be boiled regardless, is in harmony with present day thought. Marriott's preference for codliver oil over viosterol in the prevention and treatment of rickets is soundly founded. Caution against the use of cathartics in treatment of diarrhea is justly emphasized.

The author's belief that hidden otitis media and symptomless mastoiditis are commonly responsible for alimentary intoxication, and the advocacy of mastoidectomy in such cases, is still a subject for loud controversy among pediatricians, as well as otologists. One hesitates in accepting such radical advice.

The author's original suggestion of using insulin in anorexia of infancy and childhood is not mentioned in this volume; in fact the entire subject of anorexia is disregarded. The medical student and general practitioner, for whom this book was intended, will find it lacking in explicit information regarding the feeding of normal infants with milk mixtures, as well as in detailed advice concerning the administration of solid foods during the first year of life. In these respects it resembles many similar texts on infant feeding. The man who does not possess such a book will, however, find this volume generally very satisfactory.

THOMAS MYERS, M.D.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

INTERNE WANTED

An interneship will be available in the Abbott Hospital and Janney Children's Hospital, Minneapolis, beginning July 1.

This is an excellent opportunity for anyone who wishes to specialize in pediatrics. All Staff members are connected with the University of Minnesota. (See Staff list in our display advertisement on page viii.) If you have completed your interneship and wish special pediatrics training you should look into this service. Only graduates of Class A schools need apply. Physicians in practice who wish to avail themselves of this opportunity will be considered.

Apply Abbott Hospital and Janney Children's Hospital, 17th to 18th Streets, on First Avenue South, Minneapolis.

FOR SALE—One Victor Snook X-ray Machine, latest type, with Victor X-ray table and complete equipment. Exactly like new. Will sacrifice for cash. Terms to responsible party. Address D-84, care MINNESOTA MEDICINE.

FOR RENT—One room with laboratory and lamp room in suite with other doctors in Medical Arts Building. Rent and office girl total $50 per month. Address D-83 care MINNESOTA MEDICINE.

POSITION WANTED—Young lady, 23, fifteen months' laboratory and x-ray training in Minneapolis hospital. One year college preparatory. Address D-87, care MINNESOTA MEDICINE.

FOR SALE—At a bargain if quick action is obtained, established 23 year old business of Minneapolis practitioner of eye, ear, nose and throat. Records and good will, furniture, equipment and instruments. Retiring. Address D-86, care MINNESOTA MEDICINE.

WANTED—An assistant in general practice, one whose inclination is decidedly toward internal medicine, in town located near Twin Cities, good hospital and office facilities. Address D-85, care MINNESOTA MEDICINE.

WANTED—Physician for locum tenens for about two months. General practice in city of 20,000. Minnesota license necessary. Open now. Address D-80, care MINNESOTA MEDICINE.

POSITION WANTED—Experienced laboratory technician wishes position in doctor's office or hospital. Can also do stenographic work. Address D-81, care MINNESOTA MEDICINE.

FOR SALE—General practice in thriving German town in central North Dakota. Price very reasonable. Population of town 750. Address D-82, care MINNESOTA MEDICINE.

LOCUM TENENS WANTED—Physician, age 28, available for summer or any part of it. Grade A medical school. General internship, Ancker Hospital, Saint Paul. Address D-88, care MINNESOTA MEDICINE

POSITION WANTED—Experienced married clinical pathologist wants connection in Minnesota. B.S. degree. Ten years' experience. Address D-89, care MINNESOTA MEDICINE.

WANTED—Locum Tenens or assistantship by experienced physician, licensed in Minnesota. Address D-90, care MINNESOTA MEDICINE.

VOL. XIII AUGUST, 1930 No. 8

THREE CASES OF BRAIN SURGERY*

ARNOLD SCHWYZER, M.D.
Saint Paul

IF A GENERAL surgeon operates nowadays on a brain tumor there ought to be some particular reason for his doing so, because this work has become a specialty and, in our country, there are a number of the foremost masters in this field. In the last two years we have operated upon five such cases of brain lesion. In one the tumor gave no clue as to its localization. The bedridden patient was in a most pitiable condition and a subtentorial decompression was done to relieve the pain and to save the little vestige of eye sight remaining. The headaches were relieved, but the patient died soon. In a second patient already in a stuporous condition, the roentgenologist and the ophthalmologist had both made a definite diagnosis of tumor of the hypophysis. The posterior clinoid processes of the sella turcica were absent. The whole sella was greatly flattened and drawn out backward as seen in suprasellar tumors; but there was no tumor. At postmortem an infiltrating tumor of the left frontal brain was found.

The other three patients I can show you here tonight. The first two of these patients had refused to go to more specialistic surgeons after our limited experience had been freely stated, nor was there much time to lose. The third patient seemed to be less of a difficult surgical problem than the other two.

The first case, a woman thirty-three years old, was kindly referred to me on November 3, 1927, by Drs. Binger and Kamman. The salient points of the history are as follows: She had always been well up to the present illness. Three years ago she noticed a beginning deafness of the left ear, steadily increasing. Seventeen months ago, about a month before her youngest child was born, the vision became poor and she began to see double. At the same time weakness in the legs started, especially in the left. There was no pain in the legs. As time progressed she became worse, finding that she could not think as well as formerly. She would easily forget things. She had never vomited except a few times in August 1927 when she had influenza. Only once was the vomiting projectile. The patient had never had headaches or pain in the neck. There had been no preceding injury.

Upon examination, the chest and abdominal organs were normal. X-ray plates of the head showed nothing abnormal. The sella turcica in particular was normal in appearance.

Neurological Examination (mostly from notes by Drs. Kamman and Binger):

Cranial nerves:

I—Olfactory, normal.

II—Eye sight reduced to counting of fingers. Bilateral papilloedema, more marked on left, where the swelling of the nerve head amounts to four diopters; on the right side two to three diopters. Small retinal hemorrhage below in left eye.

III, IV, VI—Bilateral nystagmus, fine on looking toward right, coarse towards left. On right conjugate deviation the left eye turns somewhat down. Proptosis in left eye, 2. Lid space on left side 3 mm. larger than on right.

V—Left corneal reflex absent. Delayed contraction of left masseter and temporal muscles. Deviation of jaw toward left (Pterygoids).

VII—Weakness of central type in left facial.

VIII—Left nerve, complete deafness. Weber lateralized toward right. Hearing on the right side normal. Dr. Binger had made equilibratory tests which showed destruction of the left vestibular nerve and lack of response from the vertical semicircular canal of the right ear. All other cranial nerves normal. (No dysphagia.)

Motor system:

Arms—Left arm shows hypotonia, adiadokokinesis and intention tremor. No ataxia. Muscle strength normal. Right arm normal throughout.

Trunk—No deviation of umbilicus.

Legs—Some hypotonia and slight ataxia of left leg. Muscle strength normal on both sides.

Gait—Patient walks slowly and with a wide base.

Station—Slight Romberg, but not lateralized to either side.

Sensation—Normal throughout for touch, pain, heat and cold. Passive motion, position and vibration sense,

*Read before the Ramsey County Medical Society December 30, 1929.

stereognosis, topognosis and two-point discrimination preserved in all areas of the body.

Reflexes—On left arm slightly diminished. Left knee jerk pendular. No Babinsky or ankle clonus.

Mental—Negative. Slight slurring and stumbling over test words.

Fig. 1. Case 1. Sketch made by the operator directly after the operation to show the extent of the bone flap, the opening of the large mastoid cells, the dural flap to cover them, the exposure of the lateral sinuses and torcular Herophili, the puncture of the left lateral ventricle, the division of the falx cerebelli and the broken off posterior rim of the foramen magnum.

Fig. 2. Case 1. Tumor as it presented itself. We did not succeed in giving the proper impression of the depth of the tumor, which reached the midline in front of the pons. The mobilization of the cerebellum may be noticed and the covering of the mastoid cells by the dural flap.

Diagnostic impression (Dr. Kamman): History of progressive deafness of three years, together with choked discs, without headache but positive cerebellar signs and absence of left corneal reflex are strongly suggestive of a tumor in the left cerebello-pontile angle, probably neurofibroma of left eighth nerve.

To this may be added the data furnished by Dr. Binger, who found a complete destruction of the left cochlear and vestibular nerves and also of the fibres from the right vertical semicircular canals. They are the first ones to be damaged by pressure from the other side as they run more medially in the medulla. I. H. Jones of Philadelphia found this to be a regular and characteristic symptom in tumors of the acoustic nerve.

Most of this examination was made on October 28, 1927. The patient was then rapidly getting worse. She seemed forgetful and the stream of thought became delayed. On November sixth, I dictated: Patient is less responsive than two days ago. When asked to get up she stares and after my questioning says, after some delay, that she is thinking. When questioned what she is thinking, she answers "seriously." She declares on inquiry that it is hard for her to think. In these few days a distinct degree of stupor had developed.

Operation November 7, 1927. The operation was done entirely under local anesthesia, which was apparently perfect even during the intra-cranial maneuvers. The incision was made, with a moderate convexity upward, from behind one mastoid process to a corresponding point on the other side. From the ends of this cut the incision was carried straight down on the neck for a sufficient distance on each side. The bone was divided in a similar line as the skin incision as we had decided to retain the bone. The line of division reached a little above the occipital protuberance and ran horizontally above both lateral sinuses till near their downward bend. Bleeding from emissary veins was controlled by bone wax and compression. From the two lateral drill holes we divided the bone downward toward the foramen magnum with Dahlgren's forceps. Apparently through pressure the bone had become thin and brittle in the lower area. A Doyen chisel with a protecting projection on the under side of the bit was then inserted on each side at the lower end of the lateral bone incisions and with a stroke or two the bone was split for some distance toward the midline. It is well known that in these cases of markedly increased intracranial pressure the cerebellum is commonly wedged into the foramen magnum and that the slightest additional pressure on the medulla oblongata will cause apnea and perhaps prompt disaster. We therefore carefully pried the bone loose by using leverage low down in order to avoid an inward tilting of the lower rim of the bone flap. The bone did not break where we had used the chisels, but the posterior rim of the foramen magnum broke off in one piece with the occipital flap. In two other cases of ours with similar procedure the break occured at the desired level, but in this patient we had gone farther down and the intracranial pressure had greatly thinned out the bone, leaving intact only the strong median vertical ridge. A shearing off of the medulla was averted by the prying and steadying action of two elevators near the base of the flap, while this latter was gently and slowly raised. That no untoward symptoms followed was perhaps due to two reasons: first, that the lateral incisions of the soft parts were liberal and that therefore the occipital bone did not swivel on firm muscular masses; and sec-

ond, that as soon as the flap was somewhat raised we forcibly pulled on it straight backward with only gradual tilting, relying at the same time on the two elevators with their gentle but energetic lifting action.

The circular part of the occipital sinus (marginal sinus) which runs along the edge of the foramen magnum, was not injured. The two lateral sinuses were now freely visible in their course and all of the torcular. Enough bone had been removed so that we could tap the left lateral ventricle above the lateral sinus, in the hope of reducing the great tension. However, only a few drops of clear fluid escaped. In order to get sufficient access, the bone had to be removed to the edge of the sigmoid sinus on the left side. The *x*-ray picture had shown that the mastoid cells reached unusually far back. They had to be opened widely. Two of the cells were quite large, one of them eight millimeters long by a width of four or five. Here, Lane's forceps were most useful. The dura was then opened and the occipital sinus with the falx cerebelli divided between clamps and tied off with fine catgut. This allowed better displacement of the cerebellum. The dural incision ran about one centimeter below the lateral sinus, but on the left side a large triangular flap with a lateral base was formed in order to cover the mastoid cells. The base of this flap was at the very edge of the sigmoid sinus.

Gently lifting the left half of the cerebellum with a spatula and following the posterior aspect of the petrous bone along its lower border we reached the tumor in the depth. It was markedly deeper than I was able to indicate in the sketch. It looked bluish and cystic on account of the distended arachnoid, which covered it. Some fluid escaped when this covering was opened. The tumor itself was irregularly nodular and rather friable. No distinct capsule could be made out. The part which could be seen was, however, sharply outlined. We then gradually removed in pieces what seemed to be the bulk of it. The weight of the removed portion was nine grams. Feeling with the finger we were sure that there was some remnant left. However, we had reached forward in the midline to the clinoid area, which had not shown any signs of absorption in the roentgenogram. Toward the brain stem we could not make out a clean outline, but further advance would have greatly endangered the most vital structures. With Cushing's experience in attempts at complete removal in our mind, as related in his classic book on "Tumors of the Nervus Acusticus," it was decided to do no more, though W. E. Dandy in his publication in 1925 in "Surgery, Gynecology and Obstetrics" had demonstrated that a complete removal of these tumors may be possible. A good number of years of relief with an undamaged facial nerve was on one side of the scales, and on the other was possible complete removal of the tumor but certain sacrifice of the facial nerve with marked danger of keratitis and with great risk of prompt death. This risk appeared prohibitive because of the inability to find a line of cleavage toward the pons. On the other hand the thought of an energetic postoperative radium treatment gave us some comfort in our decision.

The dura was sutured back into place by the finest silk sutures. The bone flap was turned up under forcible pulling backward to avoid any damage at the foramen magnum. Strong forty day chromic catgut was used for muscles and fascia, which did not, however, prevent a gradually developing backward tilting of the flap. We did not remove the bone, as is usually done,

Fig. 3. Case 1. Fragments of the tumor as they were removed (natural size).

because with a wide opening to above the torcular with free exposure of both lateral sinuses the replacing of the protective shell seemed very desirable. On the other hand a more limited exposure, we felt, would have rendered the intracranial manipulations more dangerous and less gentle—at least in our hands.

At the end of the operation the patient was in good condition. Though no general anesthetic was given at any time and only 0.5 per cent novocain had been used for the soft extracranial parts (assisted by 1/6 grain of morphine and 1/150 of atropin, given before the operation), the patient moaned only once. This was when the bone flap was turned down. At no time was there interference with the respiration. During the work on the tumor the patient was motionless and breathing quietly, though conscious.

Of the postoperative course a few notes may be of interest. One hour after returning from the operating room the patient was asked by one of the doctors: "Who is speaking?" and the answer was correct. The face was not paralyzed. At 7 p. m. (six hours after the operation) she talked quite rationally and surprisingly much; in fact, this was in striking contrast to her behavior on the last day before the operation when a stupor had become apparent and she had not talked except when asked questions, and even then only slowly with a much blurred conscionsness. Now she wanted to know what was going to happen and on being ques-

tioned said she had pain, at times even a great deal, during the operation, but said "I did my best. I wanted to see this thing through." Her vision seems not damaged, she counts fingers correctly. She swallows freely without coughing afterward. She can close the eyes and whistle. Her pulse is one hundred and twenty-six.

distal end of a heavy lead tube to avoid lateral rays. The filtering consisted of one millimeter of brass (the radium containing capsule), one millimeter of lead and one and a half centimeters of wood. Fields all around the head allowed us to give 7050 milligram-hours of hard rays at one session without damage to the hair

Fig. 4. Case 1. Low power; showing palisade spindle cell strands and reticular areas; also cysts.

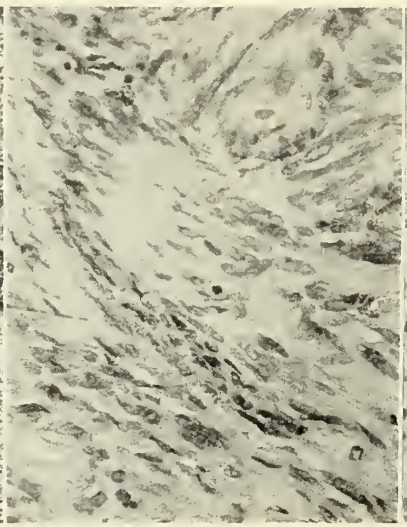

Fig. 5. Case 1. High power. Strands of spindle cells.

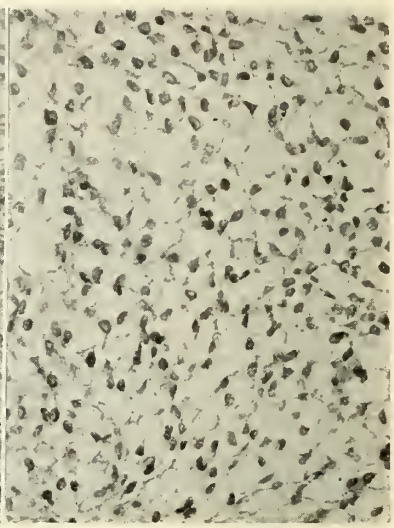

Fig. 6. Case 1. High power. Reticular area.

On the day after the operation she said she could not complain. In the evening she appeared very normal in her behavior, smiled and did not talk too much. She has a little pain where she was operated upon. Asked to multiple five times seventeen she very promptly answered: "Eighty-five." Nevertheless after a while she appeared tired out and was not sure that she had been operated upon. "Something has happened; something was done to the back of the head, but I do not know if that was the operation."

On the next day (forty-eight hours after the operation) she declared she felt better. The trigeminus, which is most frequently affected in these tumors of the acoustic nerve, due to its proximity, and whose motor root had been found paretic in our case before operation, proved not to be any further damaged, as the sharp and blunt end of a lead pencil was differentiated exactly all over the face.

On the fifth postoperative day oozing of cerebrospinal fluid required dressing. On the following day the corneal reflex, which had been absent before the operation, was found to have returned, though it was still weak and retarded. On November 14, one week after the operation, the nystagmus was much improved. Cushing considers the nystagmus in acusticus tumors to be due to cerebellar rather than vestibular disturbance. The more the cerebellum was manipulated at operation the more the nystagmus was noticed to be increased. On December 5, the patient was discharged.

A month later she returned for radium treatment. From a distance of six centimeters from the skin 75 milligrams of radium were applied. It was put at the follicles. When she came for this treatment her mental condition was not as good as it had been. This dated back to a ride over a rough road four days previously.

Dr. Kamman made a neurological examination on January 7, 1928, with the following report: "Marked subsidence of all pathologic reflexes. The corneal reflexes are now equal. The proptosis has receded and the facial palsy is clearing up. The extra-ocular palsies are about the same as at the preoperative examination. The palate rises in the midline and there is no pharyngeal anesthesia. The patient's mental condition is much clearer than on previous examination. She is well oriented in all spheres, responds fairly promptly and accurately, and expresses no hallucinations or delusions. There is some small amount of mental confusion, but not nearly reaching its former degree of intensity."

When seen again in May, 1928, a considerable further improvement was noticed. She could talk freely, the voice was stronger. She looked well, could walk alone, had gained twenty-five pounds, and had no trace of headache. Her husband stated that she was reading a great deal, books and newspapers.

On September 30, 1929, she came again for examination. Since the operation she had gained from 85 pounds to 135 pounds. She read small print very fluently. She was feeling "fairly well." There was a sensation of pressure in the head, though she had no headache. The left eye was still turned down a trifle which caused double vision in some positions.

Radium treatment will be continued for a long time at intervals, in the hope of delaying signs of recurrence.

Time does not permit us to go into a more general discussion of this subject. Prompt action was needed in our case when a distinct stupor made its appearance, and when the greatly damaged eye sight and the choked discs with a retinal hemorrhage warned us of the rapidly approaching irreparable blindness. In subtentorial tumors the papilloedema with great distension of the retinal vessels is a very regular and early danger signal. It occurs earlier and reaches a higher degree than in most other brain tumors. Nevertheless, as I might mention in parenthesis, I found it once completely absent in a cerebellar tumor of large size. This patient had free flowing of cerebro-spinal fluid from the right nostril, so-called cerebro-spinal rhinorrhea, which of course relieved the tension.*

As to the microscopic study of the case, let me say that without the help of Cushing's book the diagnosis would have been uncertain. However, Cushing has cleared up the character of these acusticus tumors and has shown that they belong in one group, are not infiltrating and are well encapsulated. They originate from the supporting structure of the nerve, which in the portion near the cerebellum is glia, while after a course of from seven to ten millimeters away from the cerebellum a transition into connective tissue endoneurium occurs. The tumor arises apparently from the incompletely differentiated supporting structure of the acusticus, and glia-like reticular areas alternate with cellular strands of long connective tissue cells which are arranged in interlacing bands and whorls. The staining qualities being somewhat different from adult tissue, whether glia or fibrous, leads Cushing to the opinion that the tumor arises from embryonal remnants. Ganglion cells may be normally found in the nerve (the cochlear and the vestibular roots have each a ganglion at their distal end) and ganglion cells are at times found in varying numbers in the acoustic tumors. These growths are always surrounded by the pia-arachnoid, because the arachnoid enters for several millimeters into the internal auditory canal, enclosing the nerve. In our sections, the picture corresponded pretty well with Cushing's description. The bulk was composed of long cells in palisade arrangement, forming interlacing strands and whorls. These alternated with areas of neuroglia-like reticular structure with fewer nuclei of a round shape and a fibrillar network between the cells. At the periphery of the tumor there were numerous cystic spaces, many of them quite large. The walls and interspaces between the cysts are of orderly design and have again palisade arrangement of densely arranged cells. They are, therefore, part of the tumor. The blood vessels showed marked hyalin degeneration, which Cushing declares to be one of the characteristics of these neuro-fibromata of the nervus acusticus.

*The case was published in the St. Paul Medical Journal in 1902.

The history of the second case is the following:

Mrs. J. G., forty-eight years old, was referred to me on May 1, 1928, by Dr. Binger because of a suprasellar tumor. Two years previously, in May 1926, the patient had had a fainting spell. She lost consciousness and had foam showing from the mouth. This occurred at night and the following morning she could not see out of the left eye. In fact, she had been able to see hardly anything with either eye for two weeks, after which the right eye improved gradually. A numbness in the left hand had been felt and she had headaches and pressure in the left frontal area, which necessitated morphin. The vision remained blurred; she could not recognize, for instance, the features of her nurse. After rest in bed for five weeks the visual acuity had improved to the point that she could recognize flowers in the room and their colors. The condition was considered by her physician to have been a stroke of apoplexy. On the second of November 1926, Dr. Binger of St. Paul was consulted on account of the very poor vision.

The left eye was amaurotic with the exception of a very limited area of perception temporally and upward near the periphery of the field of vision. The right eye had a concentric narrowing of the field of vision with a vision of six-tenths. Colors were seen centrally only.

On February 9, 1927, the field of vision had changed in a manner which became significant and led to an *x*-ray study of the case. In the left eye there was no change; there was only the mentioned small area of perception laterally, no perception in the nasal field. In the right eye, however, the vision in the temporal field was greatly reduced as compared with the findings three months before.

Roentgen pictures then demonstrated a tumor above the sella turcica. The location of the tumor made it of doubtful operability and *x*-ray treatment was tried. Four series of ten to twelve treatments each were given between May and December 1927. The headaches were considerably relieved, but the ocular findings remained very much the same. In May 1928, when I first saw the patient, she stated that for the last five weeks there had been almost a constant pain in the right side of her face shooting into the left eye, the worst pain being located in the right upper jaw area.

There were no urinary symptoms, no motor difficulties. For a while she had complained of a noise in her head, but this had disappeared somewhat.

Previous history: Eighteen years ago appendectomy and tonsillectomy.

Family history: One brother living and well; one sister living and well; one sister died from an accident.

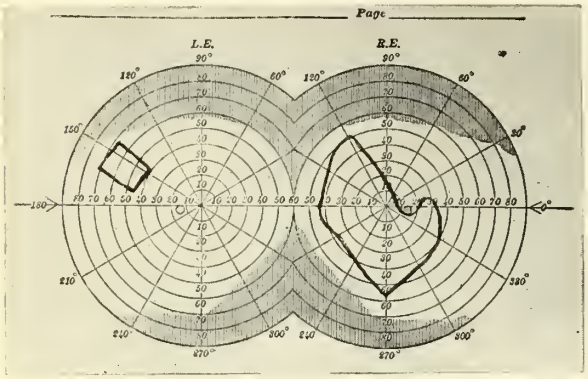

Fig. 7. Case 2. Field of vision. Moderate reduction in nasal field of right eye. Marked reduction in lateral field of right eye. Only small peripheral remnant in lateral field of left eye and complete amaurosis in left nasal field. Therefore, complete damage to left lateral nerve bundles, almost complete damage to left inner (nasal) bundles, marked damage to right inner bundles and least involvement of the lateral portions of the optic fibers of the right eye.

Marital history: Husband living and well; no pregnancies.

Physical examination: Well developed and nourished. Besides some enlargement of the heart to the left all the findings were normal apart from the eyes.

The left eye sees a hand only when it is moved, and only in the temporal field, but does not recognize it as such. The right eye is better, but the large one-inch headlines of a newspaper cannot be read: she counts fingers at two feet. The optic papillæ in both eyes are white, showing very marked optic atrophy.

X-ray of the right upper jaw, where she had most pain, showed some sclerotic thickening, but nothing further.

X-ray of the skull demonstrated a round tumor with considerable calcification above the anterior part of the sella turcica. It measured about two centimeters in height and nearly the same in width. On stereoscopic examination it was seen to be located somewhat to the left of the midline, directly above the left anterior clinoid process. A faint semicircular shadow was seen by the roentgenologist, Dr. Schons, in the antero-posterior films, about one to two centimeters peripheral to the shadow of the calcified mass, which was considered by him as suggestive of a more recent extension of the growth (as compared with previous pictures). There was no evidence of any erosion at the base of the tumor.

The olfactory sense was not affected; roses and carnations were promptly recognized through either nostril.

Gustatory sense was good; salt and vinegar were promptly recognized.

Weight, 142.5 pounds. Hemoglobin, 76 per cent. Blood pressure, 120–98. Wassermann negative.

The unusual feature, which we came to analyze properly, however, only after the operative findings, was that we did not have a bitemporal hemianopsia as we see it in pituitary tumors where the patient sees as though he is wearing blinkers; furthermore, that the left eye was much more affected than the right one

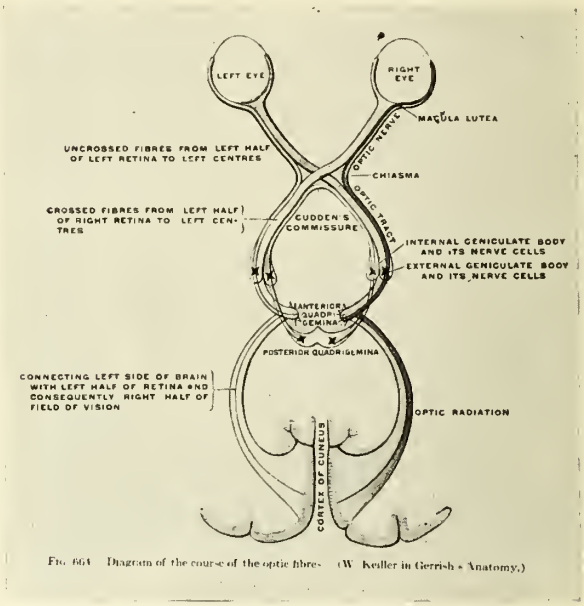

Fig. 8. Arrangement of optic nerve fibres (from Gray's Anatomy).

and that the left nasal field was completely amaurotic while a trace of vision remained in the temporal field. This would indicate that the left optic nerve was compressed from the outer side and not from the median side as occurs in pituitary tumors. The right optic nerve acted as though it was injured from the inner, *i.e.,* left side. In the lateral field the hand approaching from far laterally was seen only when it nearly reached the midline. What vision was left was mainly in the nasal field of the right eye; in other words, in the outer portion of the right optic nerve. The very marked damage to the inner optic fibres (corresponding to the lateral field of vision) of the right eye makes one think that not only the left optic nerve and chiasma, but even the left optic *tract* were affected, where besides the temporal optic fibres coming from the left eye we find the inner fibres from the right eye. By a pressure from the outer side acting on the left optic nerve at the chiasma all this would be explained.

An exploration was decided upon, and was done on May 9, 1928, entirely under local anesthesia. A large craniotomy was done on the *right* side, though the tumor was above the *left* anterior clinoid process, in order to keep away as far as possible from the center of speech. Three centimeters behind the outer angle of the orbit was the start of a somewhat mushroom shaped incision which followed the hair line to near the midline. Then about two centimeters from the midline we ran far back and turned around the parietal protuberance downward to a point about three or four centimeters back of the root of the helix of the ear.

Before doing this, the pedicle of this flap, directly over the ear, was tied off in three portions with deep reaching catgut sutures. Drill holes were then made. Between two posterior holes and again between two anterior ones we cut through with a Gigli saw to insure exact opposition on closing, while the rest of the bone

Fig. 9. Case 2. Skiagram showing calcified suprasellar area.

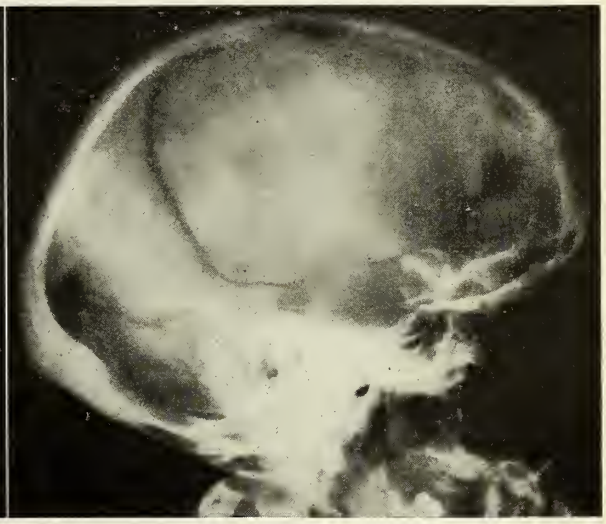

Fig. 10. Case 2. Skiagram showing extent of craniotomy.

incision was made with Dahlgren's bone shears. The pedicle was about six or seven centimeters wide. The widest diameter of the bone flap anteroposteriorly was twelve centimeters. We had difficulty inasmuch as the bit of the Dahlgren forceps broke, but as we were using de Quervain's modification of the forceps, which consists of a guard for this bit, it saved us from disaster. The head end of the table was then raised to about 40 degrees. The dura was cut about one centimeter from the bone surface with the pedicle posteriorly. Covering the brain with pads of moist cotton we gradually insert rubber strips over the frontal brain so as to protect it. The brain gradually had to be brought backward and outward. The orbital roof was laid bare, and gradually we created room. Then we came toward the clinoid process. This was a very slow process as we wanted the brain to change its form very gradually to avoid even fine lacerations. Now we could palpate in the midline or rather somewhat to the left a hard mass which was strongly pulsating. In size it corresponded to the tumor seen in the *x*-ray plate; it seemed even somewhat larger. Felt from the left lateral side, the pulsation was again directly under the finger and it was now clear that we were dealing with an aneurism of the internal carotid artery at the point of its division into several branches at the level of the circle of Willis. The dura was sewed back into place with fine linens and the bone flap replaced. A few linens in front and behind re-united the galea aponeurotica and the temporal muscle. The skin was closed by interrupted linens, closely and exactly applied. The catgut sutures (Heidenhain) at the base of the flap were left untouched. The patient was in good shape all through the operation, even during the time the frontal lobe was displaced. She was perfectly conscious. She only complained at the beginning of the skin infiltration and towards the end when we sutured the skin, because the operation had taken so long that the novocain anesthesia had worn off. At the end of the operation the patient appeared really in excellent general condition. Once during the operation when the brain was displaced she tried to vomit, but this lasted only a moment. Right after the operation she counted fingers with the right eye at three and a half feet while formerly only at two feet. This was undoubtedly due to the better light in the operating room. Her speech and sensorium seemed to be perfect. One hour after the operation the patient was reexamined; she differentiated between the smell of a rose and that of sweet peas in a very positive way. During the first twenty-four hours after the operation our patient vomited four times. She had vomited readily all her life. The menses, for instance, were always or almost always accompanied by vomiting.

We knew now what the pathology was and immediately had decided to ligate the left common carotid as soon as it could be done. The temperature remained normal, reaching only once 100° after some stitches were removed one week after the operation. On May 19th, ten days after the operation, the accompanying photograph was taken.

On May 21st, twelve days after the craniotomy, we ligated the left common carotid artery, again under local anesthesia through an incision parallel to the natural skin folds of the neck. The carotid was ligated with a forty-day chromic catgut and a few millimeters above this a silk ligature was put in to make the obstruction more permanent.

Practically immediately after the ligature of the carotid artery the patient felt better, though already since the craniotomy the pressure in the head had lessened. While she had had daily headaches for two years which had required constant use of bromides and luminal, the pressure in the head was so much better after the liga-

tion of the carotid that no such medication was any longer needed. Her head was clearer. The pain in the eyes and in the right side of the face and the right maxilla had already practically disappeared after the craniotomy and before the ligation was made.

After the ligation she vomited once, a few hours after the operation, perhaps from the novocain. In the night after the ligation she slept "fairly well." The next day she was allowed to go to the bathroom. Our patient appeared normal and clear and well oriented. Seven times eighteen, which she had not been able to figure out four days previously, was now promptly worked out as equaling 126—as promptly as only a healthy and somewhat trained person could figure. On being asked, how much was 13 times 14, she answered again surprisingly soon, 182. When we uttered our surprise at the rapidity of the answer she said she had been doing much of this kind of arithmetic in her daily work as a cashier.

Fig. 11. Case 2. Ten days after craniotomy.

An interesting surprise awaited us at this junction when we discovered, as soon as we took her away from this abstract arithmetic and asked her a most simple question of subtraction in applied arithmetic, that she was unable to answer correctly. She was unable to figure out what year she came to this country, though she knew that the year was 1928 and that she had been for twenty-seven years in the United States. She answered 1921, then 1919, then 1909 and then had to give it up. This may have been due, at least partly, to a rapid tiring.

On June 2nd the eyes were tested; and yielded about the same findings as on pre-operative examination. But on the nasal side of her right eye the patient, saw (as she thought) much better: she counted fingers at six feet. The outer optic fibres seemed therefore to have improved somewhat even in this short time. The eyes tired very rapidly and the patient declared she had seen "wonderfully well" early that morning. On that day, June 2nd, twelve days after her second operation, she was able to leave the hospital "feeling fine" as the nurse recorded.

On June 20th when the patient was brought to our office the bony apposition was perfect; no ridge could be made out.

On October 9th the patient came to our office with her sister. The record reads that she counted fingers at six feet. The patient was doing all her house work and tending to the furnace alone. It is noteworthy that the eyes had improved somewhat in the first twelve days after the ligation, but had almost remained at that level. This is, of course, what one expects in case of optic atrophy. She can read the headlines on newspapers.

Fig. 12. Internal carotid seen in its passage through the cavernous sinus and emerging upward into the cranial cavity to the side of the optic chiasm (from Testut, Anatomie Humaine).

I have seen two other patients with aneurysm of the internal carotid artery. These were cases of exophthalmus pulsans due to formation of an aneurysm of the internal carotid into the cavernous sinus. The eye was protruding severely, pulsated, was engorged, and a loud swishing pulsatory noise could be heard when the stethoscope was put to the skull. In this latter location, aneurysms are not so very rare, but of the location above the cavernous sinus, where the artery divides into its several branches, I had never seen an instance. Nevertheless, even here aneurysms have been observed.

Sitting next to my countryman and friend from student days, Dr. Adolph Meyer, Professor of Psychiatry at Johns Hopkins University, at a banquet given in his honor about six weeks after this operation, I started to speak of the case,

mentioning the *x*-ray findings, laying stress on the extramedian position over the clinoid. Dr. Meyer quietly asked, "Could it have been an aneurysm?" When I asked him in surprise how he happened to think first shot of the right thing, he answered smilingly, "Well, I have seen two such cases."

The roentgenologist had been misled by a shadow which made him suspect an extension of the "growth" since the previous examination.

Fig. 13. Case 3. Calcified tumor in parieto-temporal area.

Fig. 14. Case 3. Calcified tumor in left parieto-temporal area.

The third case was kindly referred to me by Dr. Rizer of Minneapolis. The patient, a girl of fifteen years, was first seen by me on September 17, 1929. She came with Dr. Rizer's diagnosis of a tumor in the left temporal area. *X*-ray films showed the tumor beautifully. The history was as follows: In May 1927 she began to have convulsive attacks. Even the first attack was severe with convulsions and unconsciousness. Since then many of the attacks had been milder. They appeared practically every day since May 1927, changing in severity. The attacks have always been preceded by a peculiar sensation in her tongue, which warns her to lie down. She has never bitten her tongue. Occasionally she foams at the mouth. She is never incontinent. The patient had been under the care of many doctors. Medication and diet relieved her somewhat. For the last two months she had had no medication and since then the attacks had come on at least once a day, often two and quite frequently three times daily, never more than four. The right side was always involved in the convulsions.

The general examination revealed nothing further. The patient was well developed and nourished. The pupils, eye movements and the fundi of both eyes were normal. Reflexes and position sense were normal. The blood pressure was 124—80, the pulse 70.

On close inquiry into the character of the attacks the members of the family stated that the left side of the body was never involved in the convulsions. In the mild attacks the right leg and arm were stretched out rigidly. When the attack was severe there also occurred much jerking. The light attacks were over in a few seconds, while the severer ones were declared to last four or five minutes (?). During the lighter spells the patient heard what was going on, but not in the severer attacks.

The *x*-ray plates showed a central area of mottled appearance, apparently calcified, about the size of a silver dollar, though not circular but rather boggy in outline. Around this dense area one could recognize a less distinct zone of from a half to one and a half centimeters in thickness. The mass was located slightly below the middle between the base and dome of the skull and its center a trifle in front of a vertical line drawn through the meatus of the ear. On the plates made antero-posteriorly it reached from the bone, which is intact, to a depth of five and a quarter centimeters, reaching to within about two centimeters of the midline. The inner pole was three centimeters above the orbital roof, as seen in the frontal roentgenogram.

Operation, September 28, 1929, was performed entirely under local anesthesia. The patient had 1/6 gr. of morphin and 1/50 gr. of atropin beforehand. Towels were sewed to the area previously injected with 0.5 per cent novocain, outlining the field of operation. This suturing of the towels to the skin freed us from embarrassing flapping clamps. The patient was lying on the right side with the head supported beyond the table on an outrigger head rest. Heidenhain's interrupted stitches (catgut) were used for hemostasis on the outer side of the field and at the base of the flap, forming a complete circle.

The skin was incised inside the constricting hemo-

static sutures. The flap was a little larger than the palm of a man's hand. There was scarcely any bleeding; only three or four artery forceps were applied. The periosteum was freed inward and outward along the line of incision. With De Martel's cranial drill five holes are made and with the fraise (also of De Martel) the openings were united by cutting a channel about three millimeters wide. This apparatus worked admirably and saved much time. The flap was then broken out after a cut by a Doyen chisel on each side of the base. After raising the flap there was considerable bleeding from the very tense dura. This was checked by compression with an adrenalin-saline-soaked gauze sponge. Hardly any pulsation was felt.

Fig. 15. Case 3. Calcified psammoma.

Fig. 16. Case 3. Psammoma; section through middle. Note areas of necrosis and liquefaction in central portions.

Another hypodermic of 1/6 gr. of morphin and 1/150 gr. of atropin was now given, as the patient was afraid of an epileptic attack coming on. However, it did not develop and seemed to be warded off by the hypodermic and by patiently waiting. The dura was then cut, leaving a rather broad base for this flap postero-inferiorly. In the lower part of the wound a dark grayish area was noticed and the ordinary brain formation was not seen. There was some edema of the pia-arachnoid. On palpating the index finger entered between this tumor and the rounded stretched-out adjoining convolutions. Very gradually, in order not to damage the adjoining brain, we freed the tumor, which was much harder than the brain and was well outlined. The circumference of the tumor was greatest about one or one and a half centimeters inside the surface of the brain. Gradually the finger reached to a depth of about three or four centimeters. The tumor was smaller further in and it was possible to loosen it with the finger. Finally the tumor was rather readily lifted out. Only anteriorly did it seem that the adjoining parts were somewhat shreddy; they looked like bulky suffused pia-arachnoid. Bleeding was moderate and was controlled by a wet gauze pad held gently over the brain surface. The large size of the opening in the skull and dura undoubtedly helped in preventing damage to the brain.

The patient was again threatened with a convulsion. She screamed that she very distinctly felt its coming on. She then received a third hypodermic of 1/6 gr. of morphin and 1/150 gr. of atropin. Again the attack was warded off. After a short pause the dura could be stitched back into place, though the tension seemed too great to protect more than the posterior two-thirds of the exposed brain. Healthy brain was presenting in the antero-superior part of the bone flap; however, it was protected by the uninjured lepto-meninges. The bone flap was fixed by three finest periosteum silk sutures. Linen suture of galea and skin was used. The operation lasted one hour and forty-five minutes.

Fig. 17. Case 3. Appearance of wound on day of discharge from hospital, sixteen days after operation.

Before sewing up, the patient declared she had not had any pain during the operation. The last skin stitches were, however, felt.

The general condition of the patient at the end was remarkably good. Loss of blood amounted to between three and five ounces. Blood pressure at the end of operation was 111—82.

The weight of the tumor was 66 grams.

At the end of the operation the pulse was 140, but an hour later it had come down to 116 and was regular and strong. On the following morning it was 99. Before putting on the dressings, two of the Heidenhain stitches were removed to assure sufficient circulation. The others were left to be absorbed or cut later on.

Fig. 18. Case 3. Low power. The black areas are the calcified psammomatous kernels.

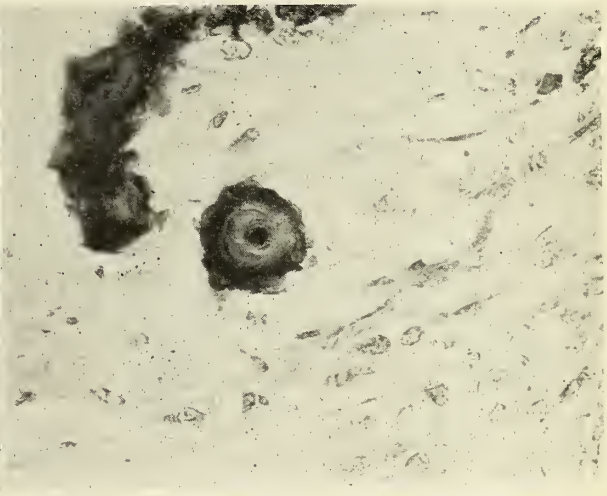

Fig. 19. Case 3. High power. Calcified amyloid body.

The first few days the patient vomited a number of times and complained now and then of pain in the head. On several occasions she had a numbness in the right hand and arm. On the day after the operation she stated the right arm and hand and the right cheek had twice felt as if they were falling asleep. This was similar to her previous prodromal symptoms. It lasted two minutes and then was gone. These sensations of numbness had disappeared after three days. On September 29th (the day following the operation) we made the note that the patient was very bright. Her right grip was a little less powerful than her left, while the sensation was equal in both hands. The facial muscles acted normally; she could whistle; she had no headache when we visited her. Both feet moved normally. She was wide awake generally and when we were leaving she wanted us to have some of the fine fruit that had been brought her.*

On September 30th, forty-eight hours after the operation, the right hand could hardly be closed and opened. There was no pain in it, while the day before it had hurt. The tongue felt numb and was sluggish. The patient was mentally much more dull than on the day before and seemed half dozing. The speech was indistinct and thick. On October 1st (three days after the operation) after a good night she seemed a little better. The right hand moved voluntarily but slowly and weakly. When asked if she had headache she answered, "Just a little, less than yesterday." She was still dull and sleepy, though she asked for a magazine and looked at the pictures.

On October 2nd, the patient smiled, looked and felt much better. Power in closing left hand was 21 kilograms by dynamometer; in right hand 12.5 kilos (patient is right handed). Pupils were equal and reacted normally. She differentiated the sharp and dull end of a nail file very promptly on both hands; also heat and cold.

Four days later I find the note: "Olfactory, gustatory senses and hearing normal. Patient out of bed." At times the right, but mostly the left hand showed the more powerful grip.

While the patient had had four convulsions on the day preceding the operation, she has not had a single one since the operation (three months). A few hours after the operation the temperature had shot up to 103.2° and stayed rather high (ranging between 100° and 103°) for ten days till the sutures were all removed. The general condition was disproportionately good and the leukocyte count reached only once as high as 10,300, to recede two days later (October 9th) to 8,950, though even at this latter date the temperature reached 101.4°. The wound looked good, but there was oozing of cerebro-spinal fluid along some stitches. This may account for the apparently aseptic fever. Sixteen days after the operation the patient left the hospital in excellent spirits and the wound was healed as the photograph, taken on that day, shows. The right hand and fingers still felt a little numb on October 18th, but the patient was perfectly normal otherwise according to the members of the family.

Microscopically the tumor was a psammoma. Topographically the tumor apparently developed from the

*This is mentioned as Hughlings Jackson (see Marion Hines "On Cerebral Localization" in "Physiological Reviews," edited by the American Physiological Society, July 1929) differentiates forms of speech: (1) voluntary or intellectual or propositional speech, which suffers most in cortical lesions; (2) emotional speech—ejaculations, swearing, which is more primitive and is unaffected by cortical lesions (the same words cannot be repeated after the emotion has passed); (3) what he calls "common speech," little sentences where (1) and (2) are interwoven. Pierre Marie considers the "center" of speech spread over a very large part of the lateral surface of the left hemisphere.

leptomeninges of the first temporal sulcus or possibly from the sylvian fissure.

SUMMARY

The three patients represent three very different lesions. The first one had a tumor of the cerebello-pontile angle. The second had an intracranial aneurysm of the left carotid artery directly above the optic chiasm and the third patient had a large psammoma in the left temporal region.

The improvement in the first case consisted of saving her vision, of mental restitution, of relief from nystagmus, ataxic gait, and of the paresis of the motor and sensory portions of her fifth nerve. This improvement had steadily progressed till now, two years after the operation.

In the second patient the remnant of eye sight, which had not yet been destroyed by the optic atrophy, was preserved and the vision has even somewhat improved, enough so that she is again a useful member of her family. The pain in her face and head is relieved and the improvement is apparently permanent.

The third patient who suffered from daily epileptic attacks for two years and four months, is, so far, completely relieved and the outlook for the future is good.*

All three cases were operated upon entirely under local anesthesia.

The reason for presenting these patients is to counteract the nihilism of despair which is found quite frequently among us and which has its disastrous effect in leading to procrastination.

*Patient has not had an attack up to the time of proofreading of this paper, ten months following operation.

THE DEVELOPMENT OF PUBLIC HEALTH NURSING

At the invitation of the United States Public Health Service, Miss Ada Newman, of the Wisconsin State Board of Health, recently prepared a statement concerning the public health nursing movement. The following is a résumé of some of the outstanding points.

Growth of the public health nursing movement in the United States was at first very slow. With the development of preventive medicine, however, the demand arose for teachers who could spread the fundamental principles of disease prevention to parents, school children, teachers and employers. After 1905, growth became more rapid and at the beginning of the World War the pioneer stage drew to a close. Well-established organizations were to be found throughout the country and a growing consciousness of state and municipal responsibility was becoming manifest. It was then that the public health nurse came into the field as an active promoter of health measures.

It is obvious that hospital training alone does not qualify a nurse to meet the obligations of public service. To meet this need for more adequate preparation many of the leading universities are offering postgraduate courses to registered nurses who have sufficient academic background to enable them to matriculate.

Public health nurses are found in large numbers in the original task of caring for the sick in their own homes. These nurses are graduates of three-year hospital training courses and were either taught visiting nursing by the staff school or took a postgraduate course.

The next largest service of the public health nurse is that of school nurse. She assists the health officer in communicable disease control, aids the school physician in examination of school children and makes home visits to interpret the findings and advice of the physicians to the parents.

Public health nursing is recognized not only from a humanitarian point of view and as an educational force but also on the basis of commercial value. This is demonstrated by the fact that business concerns employ nurses in large numbers, believing that, in order to have their plants operate on a more efficient basis, the health of the employes and of their families should be protected. Insurance companies also employ many nurses to work among their policy holders. When we consider that the only motive back of industrial nursing is a financial saving for the employing body, it speaks very highly for the economic value of such service.

The latest nursing activity to be developed in the United States is rural community nursing. These rural programs are planned to cover in part health educational work for the adult and for the school child, infant welfare, and the prevention of communicable diseases; in short, all phases of nursing service.

The demand for public health nurses greatly exceeds the supply. There are approximately 12,000 graduate nurses employed as full-time public health nurses in the United States at the present time. Many of them are doing pioneer work in rural communities and small cities and are carrying work sufficient for two or more nurses.—*Health News,* July 7, 1930.

PERICARDITIS*

T. A. Peppard, M.D.
Minneapolis

IN attempting to discuss a subject so familiar as inflammation of the pericardium, I do not desire to attempt a consideration of all of its various aspects. I do desire to emphasize certain diagnostic points, which seem to be of most value, and to call attention to certain errors and fallacies which, although they have been pointed out from time to time, still seem to persist.

For my purpose I shall cite personal experiences, and make reference to an unselected group of cases, compiled from the records of the Minneapolis General Hospital, during the past five years.

Sibson[1] presents an encyclopedic clinical discussion of pericarditis, as it occurred in his practice in St. Mary's Hospital, in London. Out of a total of 326 cases of acute rheumatic fever, sixty-three cases were affected with pericardial inflammation, fifty-four of which had endocarditis. Carefully analyzing the sex, age, and occupational factors, his tables show the two sexes affected in equal proportions below the age of twenty-one, while above the age of twenty-five males were affected three times more frequently than women.

In a group of 150 cases collected by Locke,[2] from 3,600 necropsy records at the Boston City Hospital, and in a series of seventy-eight cases, reported by Robey,[3] acute rheumatic fever was not an important etiological factor. This experience is in conflict with that of Sibson in whose series pericarditis occurred in approximately one-fifth of the reported cases. In seventeen of thirty-nine cases of acute fibrinous pericarditis, observed by Christian,[4] the pericardial inflammation accompanied or occurred just subsequent to the attack of acute rheumatic fever. Of Preble's[5] 244 cases of acute pericarditis, sixty-five occurred in relation to acute rheumatic infection. In addition to acute rheumatic fever, acute pericarditis is most commonly associated with pneumonia, local or general sepsis, and nephritis. Acute infections, such as diphtheria, scarlet fever, cerebro-spinal meningitis, erysipelas, are well known causes. Tuberculosis, occurring in 10 per cent of Preble's cases, occupied a more important place as a causative factor than in most other series. Then too it is observed as a terminal or coincidental event in cases of arteriosclerosis, hypertension, aneurysm of the aorta, mediastinal and lung tumors. Occasionally trauma is responsible for its occurrence.

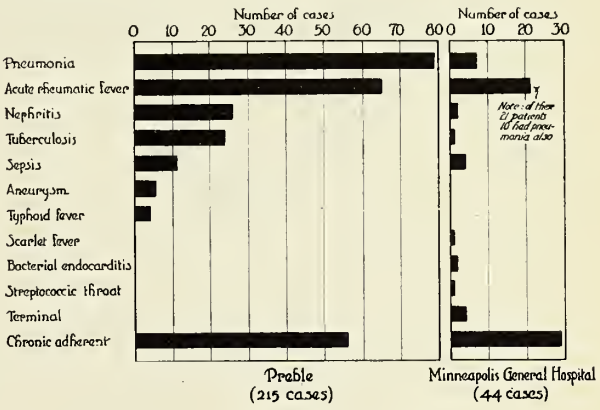

Chart 1.

From the records of the Minneapolis General Hospital during the past five years, there were found to be forty-four cases classed as acute pericarditis, most of which were seen by myself either on the medical service, or in consultation on some other service. In this group twenty-one occurred in relation to, or complicating acute rheumatic fever, or in a few instances rheumatic infection, such as acute tonsillitis, without the presence of swollen or enlarged joints. Seventeen of the patients had pneumonia, either bronchial or lobar, ten in association with their rheumatic infection, and in seven the pericarditis occurred as a complication of the pneumonia. In four cases the patients suffered from subacute bacterial endocarditis (one of these being a general septicemia associated with septic abortion). One case occurred as a complication of scarlet fever. One case was proven to be due to tuberculosis, and two complicated uremia. One case followed an acute streptococcic infection of the throat. Of the twenty-one rheumatic cases, twelve had a history of previous rheumatic infection, and also of these twenty-one cases, nineteen had evidence of mitral valve disease, either alone, or in association in 9 cases with aortic

*Thesis presented before the Minnesota Academy of Medicine, March 12, 1930.

valve disease. One case of carcinoma of the lung had a large hemorrhagic effusion into the pericardial sac, although in this case the carcinoma had not invaded the pericardium, and the source of the hemorrhagic fluid was not apparent from the autopsy report. In three cases of hypertension with cardiac decompensation, as well as in one case of severe purulent bronchitis, the pericarditis developed as a terminal event. The diagnosis of pericardial infection was made clinically in all but five cases, either by the finding of definite pericardial friction rub, or the discovery of pericardial effusion, either by physical signs, or by the roentgen examination, or both. There were no cases caused by the gonococcus. Pericarditis following occlusion of the coronary arteries, strangely enough, was found to occur only once in this group.

It is perhaps surprising that subacute bacterial endocarditis does not appear more prominently in a pathological relationship to pericarditis, for in the pathological studies made by Clausen and Bell,[6] pericarditis occurred practically as frequenty in those diagnosed as subacute bacterial endocarditis, as in rheumatic fever.

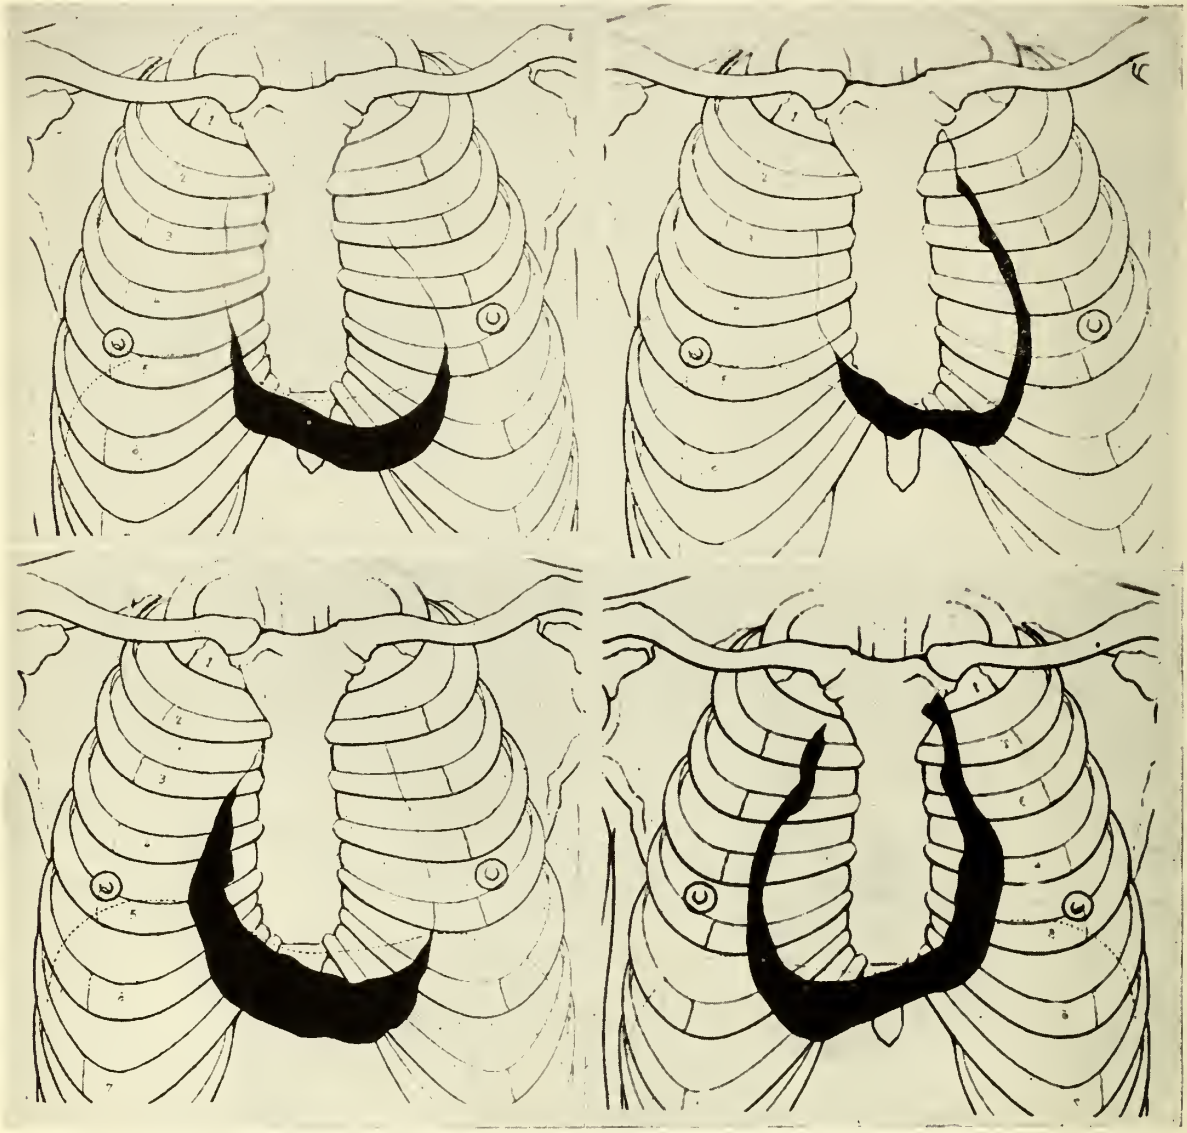

Fig. 1. Locations of accumulations of pericardial effusions. (Williamson.)

The relation of acute fibrinous pericarditis, with or without effusion, to acute rheumatic fever, and to pneumonia and pleural infection, is so well known, and so well established, that it hardly seems necessary to discuss it at length.

The use of the term idiopathic to describe types of unknown etiology seems to be of no particular assistance in classification. Perhaps it would be better to classify this group bacteriologically and

absent, or may be of a very sharp, stabbing character. Usually it is felt over the heart, but it may radiate into the abdomen, to the left side of the neck and shoulder." MacKenzie[8] states "dry

recognize that the path of invasion in these infrequent cases is not known. From a pathological standpoint subdivision may be made on the basis of the character of the exudate: fibrinous, sero-fibrinous, serous, fibrinopurulent, and purulent.

Necropsies were performed in nineteen instances. In the majority of these the exudate was characterized pathologically as fibrinous, serofibrinous, or fibrinopurulent. This exudate consisted of fresh, loose, strands of fibrin covering the pericardium in part or entirely. In eleven instances the amount of fluid was so small that the quantity was not estimated, and in two cases the loose fibrin was obviously purulent. In five other cases in association with fibrin there were amounts of fluid varying from 25 to 200 c.c., and in three the fluid was obviously purulent. In eight cases the accummulation of fluid only is mentioned, this being a clear, yellowish color, varying in amounts from 25 to 200 c.c. The 1000 c.c. accummulation of bloody fluid occurred in the case of primary lung carcinoma. The cases with the frank purulent exudate occurred in the cases of general septicemia, pneumonia, and in three instances, where the pericardial inflammation was a terminal event. In a few cases there were found old adhesions side by side with acute inflammation.

Nearly all authors comment on pain as a symptom of pericarditis, although their statements indicate that this is a variable factor. Norris and Landis[7] assert "Pain may be entirely pericarditis is essentially a painless complaint. This curious painlessness has long puzzled me. When pains are associated with pericarditis it will invariably be found that there is evidence of myocardial affection." McPhedran[9] says that pain is generally present. Sibson[1] found it in 70 per cent of his cases. Schroetter[10] states that the greater number of cases occur without pain. Poynton[11] says that it may occur with little discomfort, and no pain. Babcock[12] found pain in the majority of his cases, or at least a sense of distress. Blumer[13] states that pericarditis is often almost without pain. Billings[14] does not mention pain in his text, and in only one case history. In seventy-eight cases in Robey's[3] series pain was not a striking feature, and was observed twenty-six times. In seventeen of the twenty-six cases there was either acute pneumonia or disease of the pleura, in two others chronic disease of the myocardium, and in one aneurysm of the arch of the aorta, leaving but six cases out of the twenty-six with pain directly over the precordium. In the two cases of purulent pericarditis pain was not observed at any time. Robey observes that a good many patients with acute disease of the heart, while they do not have actual pain in the heart, generally say that local applications of ice make them feel more comfortable. Albutt states that there are cases in which the pain is like that of angina pectoris.

From a clinical and experimental study Capps[15] concluded that stimulation of the lateral walls of

the pericardium did not produce pain. Puncture of the pericardium at the level of the fifth and sixth interspaces produced phrenic nerve pain. Puncture at the level of the fourth interspace

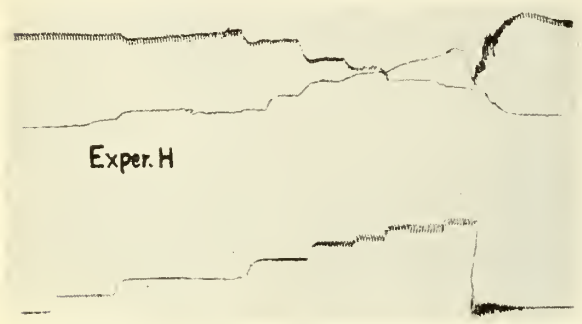

Fig. 5. Tracing showing the effect of increasing intra-pericardial pressure upon arterial and venous pressures. (Williamson-Ets.)

did not cause pain. He infers that the phrenic nerve supplies the central diaphragm and at least the lower portion of the fibrous pericardium. He believes the presence of pain in pericarditis usually indicates involvement of the tissues outside of the pericardium, especially the pleura.

In six of the present group of cases, no pain was complained of; in seven the patients complained of abdominal pain; and in three of these it was localized to the epigastrium. In the others it was spoken of as diffuse, more often of a dull rather than severe character. In the remaining cases chest pain was complained of, in eight of these characterized as precordial, in a number of others being mentioned only as left sided pain. In two instances it was complained of as being substernal. In one instance it occurred in the region of the left scapula. This varied from severe, sharp, lancinating pain to a dull sense of pressure or only a soreness. It is often increased by movement, deep breathing or coughing. Not infrequently patients were observed leaning far forward in bed, a posture which has been described as characteristic. In some instances pressure over the precordium aggravated the symptom, and tenderness was elicited. A finding mentioned in only two of the records, but which, from my experience, I am inclined to believe occurs more often than it is looked for, is hyperesthesia over the precordium.

My own experience leads me to believe that pain of some type is met with as a symptom in patients who have pericarditis. I believe that sharp and severe pains, stabbing in character, are more often associated with pleurisy, rather than its being due to the involvement of the pericardium itself. Certainly in the majority of the rheumatic cases where pleurisy is not a factor, as well as those cases occurring as a late complication of pneumonia (in these the manifestation of the acute pleuritis having subsided), the complication is either attended by no pain whatever, or else a sense of precordial discomfort or oppression. In certain instances the pain, if present, or the discomfort may be aggravated by pressure or definite tenderness may be elicited over the precordium.

Dyspnea is not infrequent although it may not appear until in an advanced stage of the disease, and more often than not is the circumstance one of increased rapidity of breathing rather than any marked subjective discomfort.

Dysphagia was not observed in any of the present series of cases. Sibson[1] mentioned difficulty in swallowing in thirteen cases. In none of the present series was loss of voice observed, although in a few the voice was husky and this may have been due to affection of the left recurrent laryngeal nerve.

Coma and delirium, commented upon at length by Sibson, only occurred in the present series of cases when they could be readily accounted for by the toxemia and hyperpyrexia.

The outstanding physical sign and the one which is most diagnostic is the pericardial friction rub. As a rule this was identified with the greatest of ease, being characteristically to and fro, being heard toward the base of the heart, the apex, or over the entire precordium. The quality of the sound varied very greatly from a fine rather high pitched, not necessarily intense, and of a grating character, to the very loud, harsh, leathery rub which occasionally may be detected on palpation, as friction fremitus. In one case of infarction, due to coronary thrombosis, the rub easily distinguishable as such, varied markedly from time to time, occasionally being very definite, and at other times hardly audible. After several days, in this particular instance, the sound became very soft and distant, and could easily have been mistaken for a soft blowing murmur. Although many authors have repeatedly commented upon the error, it still seems to be a prevalent idea that the accummulation of fluid within the pericardial sac necessarily causes

a disappearance of the friction sound. I have repeatedly carefully examined, day by day, patients showing a pericardial friction rub, the friction rub persisting at each examination while at the same time noting the widening of the percussion borders, and by roentgen examination have shown that fluid was accummulating within the sac. Williamson[16] states that the friction rub not only may, but does persist with large effusions in two-thirds of the cases. He believes that this is due to a large heart. Conner[17] comments upon the persistence of the pericardial friction murmur during an effusion.

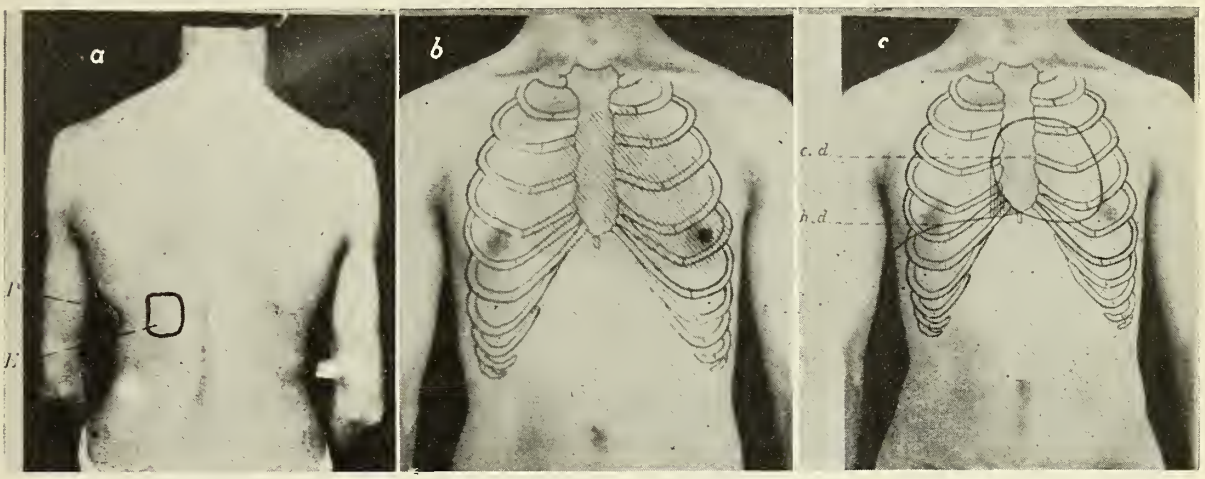

Fig. 6. Physical signs of pericardial effusion. (Babcock.) a. Location of pulmonary changes in Pins' (P) and Ewart's (E) signs of pericardial effusion. b. Apex beat and area of cardiac dullness in case of pericarditis with effusion. c. Rotch's sign of beginning pericardial effusion—dullness in shaded area or cardio-hepatic angle: *c. d.*, cardiac dullness; *h. d.*, hepatic dullness.

Evart[18] and later Christian[19] have called attention to the frequency of the so-called pulmonary compression signs, occurring over the left chest posteriorly. Evart mentions the area of dullness with tubular breathing and egophony occurring near the angle of the scapula. The area may be small or large. Christian calls attention to the fact that these signs may be demonstrated even when there is little or no demonstrable fluid present in the pericardium. Christian attributed this sign to atelectasis. He mentioned, however, the possibility of the presence of a pleural effusion as well as pulmonary infection, which often occurs, and which might confuse one in this interpretation. Inasmuch as these posterior signs are present with quite small, as well as larger effusion, I believe that the percussion findings may be accounted for in the same way as Skodas tympany is accounted for in other situations. I believe, however, that with very large effusions, atelectasis is brought about, and in such a condition signs may be accounted for in quite the usual manner. It might be of interest to comment here upon Connor's belief that the compressed lung in large pericardial effusions lies not against the vertebral column, but against the ribs, in the region corresponding to the posterior part of the axilla. He says that it is difficult for him to see how the compressed lung can ever lie against the vertebræ, for as the pericardial pouch enlarges and begins, below the root of the lung, to extend backward along the side of the bodies of the vertebræ, it must, it would seem, work its way between the vertebræ and the inner surface of the lung. With effusions of considerable size, prominence of the precordium may be observed in children, though rarely in adults. Various percussion signs have been described; some of them obviously are of great diagnostic importance. Morris and Bader[20] state that 250 c.c. of fluid in the pericardial sac is often sufficient to be demonstrated by percussion. Widening of the area of dullness, and widening of the roentgen shadow in the first and second interspaces occurs relatively early, and is best determined with the patient in the recumbent posture. Narrowing of this dull area, with a corresponding decrease of the shadow over the great vessels, when the patient is changed from the recumbent to the erect posture, is considered a most reliable sign of fluid in the pericardium. Rotch's[21] name attaches to a percussion sign which he considered diagnostic of pericardial affusion. This was the absence of resonance in the fifth right intercostal space. Hess[22] advo-

cated auscultatory percussion as a means of diagnosis in pericardial effusion. Dullness over Traube's space may be obtained.

Williamson[23] injected the pericardium with glycerin and agar and made casts. He shows that the fluid accummulates first in the lower portion of the pericardium, and that moderate amounts (500 c.c.) of effusions will serve to push down the left lobe of the liver. Evart[24] in his twelve diagnostic points mentions depression of the liver, as one of the signs of pericardial effusion. Williamson, by his injection method with small and medium amounts of fluid (350-600 c.c.) was unable to satisfactorily demonstrate Rotch's[21] sign, nor the sign described by Ebstein,[25] that is, a rounding of the cardial hepatic angle. Williamson stated that the behavior of the fluid was independent of the position of the patient, and from his experiments concluded that the best location to reach a small amount of fluid with the exploring needle was either just outside the apex or in the chondroziphoid angle (Marfan's point). Various authors have different choices as to the most desirable point of inserting a needle, or doing a paracentesis. Pendlebury[26] states that this is best done in the fifth left intercostal space, one inch from the margin of the sternum. Connor states[17] that the needle should be inserted either at a point well to the left and below the position of the apex beat, or over the area of flatness posteriorly. He prefers the posterior tap, as being the simplest and safest. I have aspirated at this site, and also in the fourth and fifth interspaces, just to the right of the sternum. Williamson and Ets[27] make a plea for not delaying aspiration too long. They state that a not inconsiderable number of patients, with uncomplicated pericarditis with effusion die as a result of pressure from the exudate mechanically shutting off the great veins. This danger is not necessarily proportionate to the size of the exudate, but rather to the rapidity with which the effusion develops. A steady fall in the arterial pressure, and particularly a sudden increase in the rate of fall is a direct indication for therapeutic puncture. In supporting their contention they performed the following interesting experiment. To determine the relation between arterial, venous, and intra-pericardial pressures —with cannulas inserted into the carotid artery and jugular vein, to record the arterial and venous pressures, they inserted a cannula into the pericardium and injected physiological salt solution. The pressure within the pericardium was gradually raised until the heart stopped beating. The increase in pericardial pressure caused a steady rise in the venous and a steady fall in the arterial pressure. In my experience, it has seldom been necessary to do paracentesis in rheumatic pericardial effusions.

In 1873 Kussmaul[28] described as a characteristic symptom of the obliteration of the pericardium, change in the arterial pulse, it becoming smaller or disappearing entirely on inspiration, and returning to normal on expiration, so-called pulsus paradoxus. Gauchat and Katz[29] described a case of pericardial effusion, which brought about this change in the pulse, and noted that the abnormality disappeared after pericardial paracentesis.

Following the suggestion of Wenckebach,[30] injections of air into the pericardium following aspiration has been done with the idea of preventing formation of adhesions. Troisier, Jacquelin, Gayet[31] and Castex[32] report cases treated in this manner. One case of tuberculous pericarditis, with a large effusion, has come under my observation, which had pneumopericardium performed. The procedure, no doubt, will not have widespread application.

There has been much discussion and comment as to whether the heart is displaced in event of the accummulation of pericardial effusions. Calvert[33] states that the position of the heart in pericarditis depends upon the size of the heart, and that the size in turn is dependent upon the degree of distention or amount of blood within the heart. While compensation is maintained the heart contains a relatively normal amount of blood, and is in a relatively normal position. When compensation fails the amount of blood delivered to the heart is diminished. The heart becomes smaller and smaller until collapsed, the size of the heart varying inversely as the pericardial pressure. The apex is in the normal position, or displaced slightly backward or to the right.

Nephritic and uremic states frequently have associated pericarditis. Bright[34] reported an incidence of 8 per cent, Sibson the same, Preble and Barach[35] each 11 per cent in 300 and 162 cases respectively. At autopsy little fluid is found as a rule, but usually there is a thick bread-and-butter-like exudate, covering the entire precordial

surface. In only four of Barach's cases did the culture show pyogenic organisms, and in these cases the inflammatory reaction was of the polymorphonuclear type. In the cases in which no

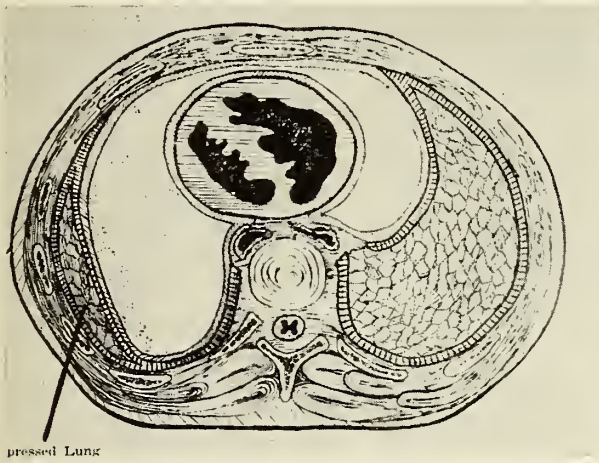

Fig. 7. Semidiagrammatic section illustrating author's view as to the usual position of the compressed left lung in the presence of a large pericardial effusion.

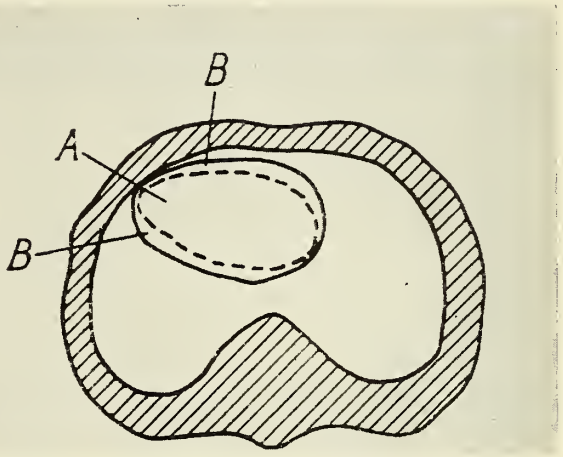

Fig. 8. Cross section of thoracic wall and of heart. Dotted line = size during systole. (Connor.)

growths were obtained the reaction was of the mononuclear type. In 90 per cent of Barach's reported cases the diagnosis was made by the presence of a friction rub. The average length of life after the appearance of the rub was twenty-nine days, although one patient lived as long as one year. In one case, under my observation, the friction rub was observed in September, and the patient did not succumb until the following March. The immediate cause of death in this case was pneumonia.

Attempts have been made to identify conduction changes which might be considered as an aid in the diagnosis of pericardial effusion. Oppenheimer and Mann[36] found electrocardiographs of low voltage associated with large effusions. These were not necessarily associated with change in shape, although it is conceivable that the effusion may alter the electrical axis in some cases, or cause other changes in the propogation of the electrical impulse. Large effusions may fail to effect the voltage appreciably in certain cases. Gauger[37] pointed out the effects of increasing intra-pericardial pressure on systemic blood pressure, as shown by Lewis[38] and refers to investigations by Kuno[39] who showed that the circulation ceased when the intra-pericardial pressure equalled the venous pressure. He reports a case of auriculo-ventricular block accompanying a large pericardial effusion, and shows tracings after paracentesis which were normal. He believes that this is due to compressive effect of the pericardial effusion upon the coronary circulation. The contention that low wave amplitude might be considered evidence of pericardial effusion was certainly not indicated by the electrocardiographic tracings in the present series, the signs observed in these being only those which could be explained by the cardiac pathology, or, as was the case, quite normal appearing tracings.

ADHERENT PERICARDIUM

Discovery of adherent pericardium during life is in many cases impossible, and in some doubtful or difficult. When the adhesions are partial, when the heart is small or when the relation between the heart and lungs is undisturbed, the diagnosis at best is doubtful, and if made rests upon speculation only. Vaquez[40] states that where layers of pericardium are simply adherent the condition is often unrecognized and is relatively benign. When, however, in association with the adhesion of the two layers of the pericardium, one to the other, adhesions are also present to the neighboring structures, the heart becomes immobilized in the chest and will have its function materially interfered with, decompensation eventually resulting. Just as acute pericarditis has many and varied causes, so the result, adherent pericardium, has the same causative factors, namely, the infectious diseases, pneumonia, scarlet fever, rheumatic infections, tuberculosis, nephritis, malignant disease, and occurs in association with, and as a result of such conditions as aneurysm and mediastinal tumors. The adhesions may be partial or com-

plete, varying greatly in extent and consistency. Partial adhesions take place most frequently near the apex and along the line of the ventricular septum, and the outer side of the right auricle, also about the base of the heart in the region of the great vessels; in short, where the extent of the movement of the heart is least. Adherent pericardium is one of the frequent causes of enlargement of the heart. Sibson compared a group of cases of valvular disease, in which the pericardium was adherent, with the same type of cases in which the pericardium was not adherent. The weight of the heart in cases of valvular disease with adherent pericardium (13 cases) averaged 120 grams, larger than those hearts with valvular disease, but without adherent pericardium (63 cases). Head[41] studied fifty-five cases of chronic adherent pericarditis, all of which were verified by post-mortem examination. He subdivides his cases into three groups: first the silent group (five cases), there being no subjective or objective symptoms, and the true nature of the disease being discovered only at autopsy. In his second group (67 per cent) the symptoms and physical signs pointed to a disturbance of the circulation, and congestive failure was the outstanding feature. His third group (eleven cases) were those commonly known as Pick's disease, the symptoms and signs of this group suggesting cirrhosis of the liver. Pick[42] sums up the results of his observations as follows: "There is a symptom complex which is deceptively similar to the mixed forms of cirrhosis (with swollen liver, marked ascites, but without icterus) and which is due to the fact that the circulatory disturbances caused by a latent pericarditis lead to proliferation in the connective tissue in the liver, and having, as a result, through stoppage of circulation in the portal vein, very highgrade ascites. This condition occurs generally in young individuals, but it is also observed in later years. The following points are guides in the differential diagnosis; the failure of the etiological factor for cirrhosis of the liver; the anamnestic report of previous pericarditis and previous edema of the legs. Systematic examination of the heart can alone lead to a trustworthy result."

Discussion of Cases. Twenty-eight cases were classed as adherent pericarditis. In reviewing the records, it was believed that from the recorded data in eight cases there was insufficient evidence at hand to properly make such a diagnosis. Of the twenty cases, thirteen had definite history of previous rheumatic infection. In most of these, this was a true rheumatic fever, although in the case of two or three, repeated attacks of tonsillitis or attacks of chorea were included. Of the remaining seven cases one was associated with syphilitic aneurysm of the aorta, one was associated with chronic pulmonary tuberculosis, and a third had had an occlusion of the coronary artery. One of the patients who had a history of previous rheumatic infection, but had no evidence of endocarditis, suffered from congestive failure, which was the result of an essential hypertension. This patient's history included a previous hospital admission, when he had suffered from an acute pericarditis. Sixteen were considered to have definite evidence of valvular disease, either mitral or aortic involvement, or both. Eleven cases had rather definite congestive heart failure of varying degrees.

Enlargement of the heart is an almost invariable accompaniment of adherent pericarditis, and is of such frequency as to make difficult the drawing of hard and fixed lines of differentiation. The latter lesion undoubtedly produces cardiac hypertrophy, and subsequently dilatation. Some of the largest hearts, met with at the necropsy table, can be accounted for in this way.

In cases of adherent pericardium retraction of the lower ribs opposite the attachment of the diaphragm on the lateral or posterior aspect of the thorax may sometimes be seen. This sign, to which Broadbent's name is attached, was considered by him, and is probably still to be considered a most important finding, when present. This phenomenon is best seen when the patient is sitting in a good light, the thorax being inspected tangentially from behind, and is more often seen on the left side. It may also be observed on the right, and when so observed is of even greater importance. It is more marked when deep inspiration is made. Broadbent[43] says: "Here, it is not possible that the heart can be directly fixed to the chest wall, at the points of retraction by pericardial adhesions, as the lung tissue intervenes; but the explanation seems to be the following: The heart is, by means of the pericardium, adherent not only to the central tendon of the diaphragm but probably also to a large area of the fleshy or muscular portion of the diaphragm, and it may be, to the anterior thoracic

wall as well. As it contracts it drags upwards and inwards the less resistant fleshy part of the diaphragm towards the central tendon or anterior chest wall; hence the points of attachment of the digitations of the diaphragm to the lower ribs and costal cartilages are dragged inwards and downwards."

While commenting on the important significance of this sign, I need to specify that it is not pathognomonic. In five autopsies on patients with adherent pericardium, in the present series, Broadbent's sign was observed and recorded in only one. Also I might mention a patient with tremendous cardiac hypertrophy, the result of a long standing hypertension, in which systolic retraction was seen during life on both the left and right sides posteriorly. The necropsy did not show any involvement of the pericardium or surrounding structures.

The pulsus paradoxus of Kussmaul[27] previously referred to, may be considered one of the important signs, which may occur as a result of an adherent pericardium. Kussmaul explained his conception in the following way: "Pericardium thickened, partly by callous membrane and fibrinous growth, inside as well as out, partly through increased thickening of its fibrinous layers, causing a definite inclination to obliterate the cavity. In the mediastinum it produces a callous skein and compact threads, which extend upward from the pericardium to the arch of the aorta, innominate vein, surrounding the stem of these vessels, drawing, kinking, and twisting them, binding the arch against the pericardium, and joining the vessels directly to the upper part of the breast bone. The pulse in all of the arteries will be small or disappear entirely during inspiration, and return to normal during expiration. The veins in the neck, especially the bulb of the jugular vein, will be swollen during inspiration." Kussmaul further cautions that a paradoxical pulse can occur in other conditions found in the mediastinum, and that a careful consideration of the symptoms and physical signs, as well as history, must be considered before making a diagnosis of mediastino-pericarditis.

Gauchat and Katz, already referred to, considered in two papers the causes of pulsus paradoxus. They considered the occurrence of this phenomenon and abnormality of the respiratory tract, and believe it to be produced by modifications of the intrapleural pressure. They experimentally showed that adhesions need not be attached to any particular vessel, but may be fastened anywhere between cardiac structures, and thoracic parietes, and still be capable of producing pulses paradoxus. Mechanical compression of the aorta produces an immediate effect upon the amplitude of the pulse. Compression of the pulmonary veins caused a decrease in pulse amplitude after one or two beats, and compression of the vena cava had the same effect after three or four beats.

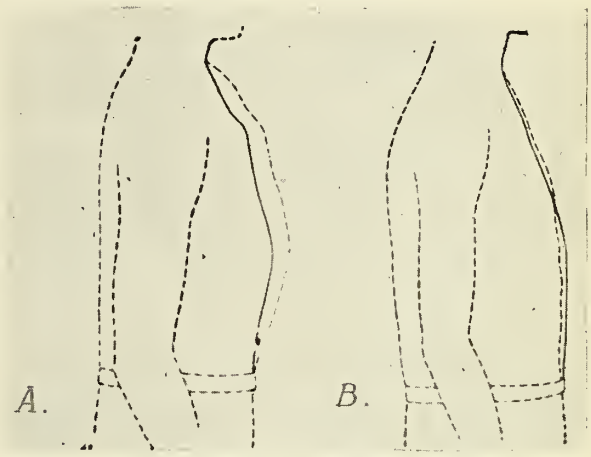

Fig. 9. a. Normal respiratory profile. Solid line, deep expiration; dotted line, deep inspiration. b. Wenckebach's crossed profile.

All of the signs advanced as indications of adherent pericardium, Skoda's[44] "dimpling," retractions of the chest anteriorly and posteriorly, retraction of the epigastrium, percussion changes obtained with the patient in various postures and during various stages of respiration, the extent of the absolute dullness and its relation to the superficial dullness, Wenkebach's crossed respiratory profile, are not pathognomonic. The character of the apex beat, and the diastolic shock are of doubtful significance. Abnormal filling of the neck veins, and their diastolic collapse, and dilated veins over the anterior thorax may be significant in indicating some interference with venous return.

A means of investigation which may prove to be of considerable help is the electrocardiograph. Dieuade[45] studied a small series of patients in this way. Normally there is a change in the form and amplitude of the electrocardiographic waves on shifting the subject from the right side to the left side. This change is due to a rotation of the heart, and consequently there is a change

in the electrical axis. It is marked in most patients with heart disease, and cardiac enlargement does not prevent the usual change. A small series of patients were shown to have no significant change in their electrocardiographic record with a shift in position. All of these who came to necropsy were found to have important lesions involving both the pericardium and mediastinum. Of a larger series of patients with clinical signs of adherent pericardium, whose records all showed a marked change, none were found to have lesions both of the pericardium and of the mediastinum. It is suggested that fixation of the electrical axis determined by this means may serve as objective evidence of a lesion involving both the pericardial cavity and the mediastinum.

Surgical attempts at freeing the heart so handicapped by adhesions have become more frequent since the advice and communications of DeLorme in 1898 and Brauer in 1902. The procedure advocated by Brauer is the one more frequently employed, rather than the more formidable manipulation of DeLorme, which involved forcible breaking up of adhesions present. In brief the operative procedure consists in removing portions of those ribs to which the pericardium is adherent. As a rule portions of the third, fourth and fifth costal cartilages are removed, with their anterior periosteum, in such a way as to make the chest wall more mobile. Bourne[46] reports twenty-five cases of cardiolysis, and from a consideration of the case histories and results obtained his enthusiasm seems justified. He states that its efficacy in severe heart failure is apparent, and the operation logically should be performed in failure of lesser degree, due to adherent pericardium. The chief indication for the operation is heart failure of whatever degree accompanied by adherent pericardium. The chief contraindication to the operation is the presence of some severe, progressive rheumatic lesion, such as advanced mitral stenosis.

One patient of the present series was subjected to this operation, and the results obtained surely justified the procedure. This patient, a young man of twenty-five, had been under observation over a period of two years, and during several hospital admissions. Acquiescence to the advice for surgical interference was postponed for many months, and the operation was performed only after the patient had been confined to bed with congestive failure for a period of three months, without improvement. Subsequent to the operation the patient was relieved from the substernal distress, dyspnea, and palpitation from which he suffered, and he was then able to be up and about for a period of six months prior to his death from heart failure. We have always regretted that this patient did not submit to operation when he was first advised of its desirability.

CONCLUSIONS

Acute fibrinous pericarditis is not difficult of diagnosis, pericardial friction being its most significant symptom.

Pericardial effusion is not difficult of diagnosis, provided that the patient is followed from day to day with careful physical examination.

The presence of a pericardial effusion does not preclude the hearing of a pericardial friction rub.

Most pericardial effusions caused by rheumatic infection do not require paracentesis.

Adherent pericardium presents greater difficulties of diagnosis and there are no signs which can be considered pathognomonic.

Of the valuable signs, that described by Broadbent is most suggestive, especially when its occurrence is noted on the right side.

As a palliative measure the operation of cardiolysis is of considerable value, and should be recommended more frequently.

ACCEPTED AND NONACCEPTED VIOSTEROL PREPARATIONS

When the question of accepting preparations of irradiated ergosterol arose, the Council on Pharmacy and Chemistry adopted a common name, viosterol, for this product. This name is not protected by trademark or copyright. It appears to have been generally adopted and is used by all manufacturers whose products have been accepted by the Council, with modifications to indicate composition and strength in vitamin D, as viosterol in oil 100 D and cod liver oil with viosterol 5 D. These products are all required to be physiologically standardized according to the method given in New and Non-official Remedies and may be relied on to have the composition and antirachitic strength claimed on the label. Therapeutic claims other than those permitted by the Council are not made for them. While it is desirable that the short, concise descriptive name viosterol be generally adopted to designate irradiated (activated) ergosterol, there is a danger that it may be used in connection with some preparations in such a way as to give the impression that a product that has not been considered or accepted is one of those accepted for inclusion in New and Non-official Remedies. In order not to waste his time and his patient's money (or worse) by using a product of unknown strength or composition, the physician should make certain that it has been accepted by the Council on Pharmacy and Chemistry. This can be determined by a statement to that effect on the label of the product, by the occurrence on the label or package of the seal which the Council permits manufacturers of accepted products to use, or by direct inquiry to the American Medical Association. (Jour. A. M. A., June 14, 1930, p. 1923.)

TOBACCCO ADVERTISING GONE MAD

The modern tendency for advertisers of all kinds of merchandise to drag the health angle into their advertisements is one of the most disturbing features in the modern advertising field. The medal for the most horrible example would seem to go to the American Tobacco Company in the exploitation of Lucky Strike Cigarets and Cremo Cigars. The exploiters of Lucky Strike Cigarets have claimed that 18,000 physicians have testified that "the heat treatment, or toasting process, applied to tobacco previously aged and cured" is likely to free the cigaret "from irritation to the throat." There was also started a campaign, "Reach for a Lucky instead of a Sweet," in which—either directly or by implication—young women were urged to smoke Lucky Strike Cigarets when they had a desire to cat candy, or pastry. Another branch of the American Tobacco Company's business has been carrying on an advertising campaign for "Cremo" cigars in which the public is led to believe that most cigars are handmade and have their tips finished off with the saliva of the individual workman. Physicians will readily admit that many young women eat more candy than is good for them, but they will certainly not agree that the substitution of cigarets in such cases is in the interest of public health. Physicians may also admit that, theoretically, it is possible for disease to be transmitted by means of cigars. But when one considers the millions of cigars that are consumed annually and that it is extremely difficult to find in medical literature any real evidence of the transmission of pathologic bacteria by means of cigars, the campaign of the Cremo concern stands condemned. (Jour. A. M. A., March 15, 1930, p. 810.)

FIRST INFECTION BY THE TUBERCLE BACILLUS*

Arnold S. Anderson, M.D.
Executive Secretary, Tuberculosis Division, State Board of Control
Saint Paul

IN THIS discussion, first infection with tuberculosis is considered the entrance of tubercle bacilli into the body in sufficient numbers to produce a positive tuberculin test. *X*-ray evidence may or may not be present. Recovery may ensue or death may follow. Reinfection is considered the entrance of tubercle bacilli into a body that has developed the response shown by a positive tuberculin test.

My purpose is to bring forth the latest opinions as to whether first infection leaves an asset or a liability to the body in our present civilization; whether it protects against progressive tuberculosis or whether susceptibility is increased. In dealing with this question, certain premises must be assumed.

1. For purposes of our study, it must be accepted that the immunity phenomenon in rabbits or guinea pigs is fundamentally the same as in humans. Injection of tubercle bacilli into these experimental animals produces tubercles as in humans and as far as we know the body's method of resisting is comparatively the same. The immune mechanism in the two is the same, but the capacity or power to respond may vary.

2. We must agree that dosage is one of the most important factors in establishing the presence of lesions both in the infected and non-infected body. In comparing, therefore, the difference in resistance of the non-infected and infected organism, we must assume that equal doses of tubercle bacilli are being given.

3. It must be accepted that many first infections as well as reinfections occur without any noticeable symptoms.

In our work with the human family, we are handicapped in this study by the following factors:

1. Our inability to measure the dose of tubercle bacilli entering the body.

2. Lack of knowledge as to the number of inoculations received and their time intervals.

3. Insufficient control over those being observed. Some will observe with great care and diligence the rules of life laid down as to rest, diet and freedom from strain, while others will carry heedlessly on as before, their chief cooperation being to return for further examinations. The tuberculous process will surely behave differently in these two types.

The behavior of first infection and reinfection has been a study ever since the days of Dr. Robert Koch who first reported on the variation in response of animals inoculated with tubercle bacilli the first time and succeeding times. He showed that a given inoculation of virulent tubercle bacilli into a non-infected animal would leave an apparently healed wound until the tenth or fifteenth day when deep ulceration would occur and the wound would discharge until death followed in a few weeks. A similar inoculation into an animal that had recovered four to six weeks before from a sublethal dose, produced within the next two days an indurated area resulting in a superficial ulceration which in turn rapidly healed. The neighboring lymph glands did not become involved in the latter instance. The bacilli were kept localized and were prevented from wide dissemination throughout the body. The body, in other words, resisted the invasion. This peculiar response of a previously infected animal to reinfection was called the Phenomenon of Koch. Later investigators hastened to repeat this experiment, but failed to produce the same phenomenon. Further work showed that their failure was due to too severe initial infections and not giving ample time for the body to develop sufficient immune reactions. It was found that in a too severely infected animal even a small second dose of bacilli would produce a fatal tuberculin intoxication. When this fact became recognized, however, and when proper initial doses were given followed, in the case of the guinea pig, by at least a fifteen day interval before subsequent inoculations, the phenomenon of Koch was then observed. Proper doses and proper time intervals between inoculations, therefore, were found to be necessary for the establishment of a relative state of immunity.

*Presented before the Trudeau Medical Society at Pokegama Sanatorium, June 7, 1930.

This work on the laboratory animal stood without question to be equally true of the human family until recently when the results of tuberculin tests supported by *x*-rays in children attracted such widespread attention. The work of Opie,[1] McPhedren,[1] Myers,[2] Chadwick,[3] Rathbun[4] and many others impressed us with the great prevalence of tuberculous infection in children and showed that first infections, which look so forbidding on the *x*-ray film, in most cases lead to an uneventful recovery. The large pneumonic areas as well as the greatly enlarged lymph glands of the hilum were shown on subsequent examinations to become smaller and smaller and ultimately to clear up leaving nothing but a calcification to attest for past events. The work on childhood tuberculosis during the past few years has proved quite conclusively that the prognosis in first infection by the tubercle bacillus is favorable. The fact also was brought out that of the adult tuberculosis, 50 to 75 per cent had evidence of previous childhood lesions as shown by calcifications. Undoubtedly, still more had evidence that was not found. In fact, 100 per cent must have had a previous first infection, otherwise they would not have developed the adult form of tuberculosis. Now the fact that so many people have been found to have been at one time or another during their early life victims of first infection, the added fact that childhood tuberculosis was shown to be very curable and again that the most frequent cause of death was adult tuberculosis rather than first infection made some people wonder as to the accuracy of our past observations. And may it hurriedly be said that there was sufficient reason for wondering. The facts produced leave no doubt but that the body quite readily overcomes first invasion by the tubercle bacilli. The question that remains, however, is whether the body in its non-infected state is a greater barrier to the development of progressive and fatal tuberculosis than is the already infected body with its allergy. Lack of conclusive evidence in this matter is due to an absence of human experimental animals upon whom equal doses of tubercle bacilli could be given to infected and non-infected persons. This would give us definite first hand information. As it is, we are forced to resort to conclusions based on ordinary laboratory animal experimentation and assume that the same immunity phenomenon is also present in man. There are a number of things which point to the fact that these are fundamentally the same.

1. Initial infection in both man and animal leads to an involvement of neighboring and distant lymph glands. In other words, the tubercle bacilli spread freely through the lymph channels without much apparent resistance.

2. Reinfection in both man and animal is characterized by a lack of lymph gland involvement and a tendency toward localizing the tuberculous process. In chronic pulmonary tuberculosis in the human, this is shown by the frequently observed apical process which tends both to remain localized and to heal with no appreciable enlargement of the hilus lymph nodes. In the animal, it is noted by the observation that a subcutaneous inoculation of tubercle bacilli in an infected animal results in a localized superficial ulceration within a few days time which tends to heal leaving no lymph gland involvement as seen in the first infection case.

3. In both man and animals, a positive tuberculin test is obtainable after first infection.

From what has been said, it appears quite safe to assume that infection phenomena observed in the animal also take place in man. It is most likely that fundamentally they both react the same to the invasion of tubercle bacilli.

Much work has been done since the days of Koch on the results of animal infection by the tubercle bacillus. The contributions of Krause,[5] Baldwin,[6] Gardner,[6] Calmette,[7] and many others have more than confirmed the original observation of Koch that initial infection in animals gives a relative immunity. The recent work of Soper and Dworski[8] in this respect is also very convincing. They studied tuberculous meningitis in the infected and non-infected rabbit. The series consisted of three groups: (1) Animals that had been infected a few weeks previous by virulent tubercle bacilli and recovered; (2) animals inoculated with heat-killed bacilli a few weeks previous; (3) non-infected animals.

After inoculating these three groups with an equal dose of virulent tubercle bacilli into the meninges, he found that the previously non-infected rabbits succumbed to extensive and massive tuberculosis; those vaccinated with heat-killed bacilli lived much longer, but finally died of progressive disease; the rabbits vaccinated with virulent bacilli mostly recovered leaving evidence of healed tuberculosis. His conclusion was

that a previous infection lent a protective influence to the organism.

The work of Rich and McCordock[9] on infection by the tubercle bacillus is most interesting. As opposed to the school which maintains that allergy is a manifestation of immunity, they assert that allergy is a separate and distinct entity and rather than being an aid to immunity is perhaps a detriment to it. Allergy will at times produce severe necrosis which surely is very destructive to tissue and can hardly be considered a benefit to the organism. In support of this view, they cited as examples previously infected animals that have practically lost their allergic response to tuberculin, but whose ability to localize and kill tubercle bacilli at the site of injection is very much in evidence. The immunity mechanism appears to be unimpaired even though the allergic phenomena have practically disappeared. They favor the idea of desensitizing patients with small doses of tuberculin which will lessen allergy, but retain immunity. The work of Rich and McCordock sounds very convincing and it is quite possible that tuberculin therapy may again return for more general usage particularly if this new indication means anything and also when we consider the new tuberculin perfected by Long and Seibert of Chicago.

In an attempt to obtain the latest opinions on this important subject, a personal letter was sent to a number of our outstanding tuberculosis workers asking for their present views on first infection.[10]

Dr. Lawrason Brown answered as follows:

"It seems to me without any question that the first infection renders one less susceptible to active and progressive tuberculosis. Of course, this susceptibility may die out. It is also possible that the first infection may help to localize succeeding infections in the lung rather than permit them to pass through into the glands.

"Have you seen the recent work of Rich in the Johns Hopkins Bulletin? It is most interesting."

Dr. Eugene Opie gave this reply:

"A healed or healing tuberculous infection, I believe, confers immunity but the first infection if sufficiently severe may be a grave danger.

"I am sending a reprint discussing this question."

Dr. Leroy Gardner replied:

"In reply to your letter of April 23rd, I may state that the opinion prevails today that a first infection with the tubercle bacillus confers a condition of hypersensitiveness and of relative immunity upon the tissues of the rest of the body, and that these states persist as long as the primary infection maintains any degree of pathological activity. Therefore, I would say without hesitation that the child who has been infected with a minimal number of tubercle bacilli is in a much better position to cope with subsequent infections than if he had never come into contact with the tubercle bacillus. If you care to go further into the subject, I would suggest that you refer to Colonel Bushnell's book, A Study on the Epidemiology of Tuberculosis, published by William Wood and Company, 1920. Colonel Bushnell went very thoroughly into the subject of tuberculosis developing in the aboriginal races which had never had previous contacts with the tubercle bacillus. In this work you will find references to the literature which should prove helpful to you."

Dr. Edward Baldwin answered:

"I was out of town soon after your letter came so simply sent you one of our 1921 reports as the best answer I could make to your question. Possibly you had read the article of Dr. Gardner and mine before.

"Personally, I never could accept the idea that one infection if it is mild would cause an increased susceptibility to later infection or to an active disease from a later infection. The difficulty is in separating the cases who are latent and active from those that are healed. If the first infection becomes latent but never quite healed, of course we never should confuse those with the kind that leave no after effects. No doubt infections occurring in adolescent ages are more serious because they hang on and develop into progressive disease during early manhood and womanhood. Experimentally we know that mild infections do change the character of subsequent ones, even overwhelmingly bad ones. That is, a secondary infection which may be called super-infection is made a chronic progressive disease rather than acute."

Dr. H. J. Corper replied with this interesting letter:

"I am not surprised that there is considerable discussion regarding the results of first infection by the tubercle bacillus. I might say also that my opinion on this is probably worth as much as every one else's. The reason for this discrepancy of opinion is easily understood when one realizes that probably all of our tests available today are more or less tests of allergy and not of immunity. I think this was very well brought out in Drs. Rich and McCordock's recent article in the Johns Hopkins Bulletin. Of course, we have been text-book bred in the conception of allergy and we are hardly to be blamed for thinking allergy and immunity run parallel. If beliefs, however, are permissible, I should like to dissent with this opinion and point to the fact that allergy is a double-wedged weapon balanced by that unfortunate condition, anergy.

"I believe that there is still much work to be done in the study of immunity in tuberculosis and especially in a segregation of immunity from allergy and this cannot be done unless we enter fully into an understanding of whether the mere inflammatory reaction of allergy is destructive to the tubercle bacilli or merely acts as a diluent and under favorable conditions may not be a good focus for the development of the bacillus unhampered. The solution of these problems must

come eventually when we have a fuller appreciation of the tubercle bacillus as the real disease producer and strike at the problem on a quantitative basis as body cell to tubercle bacilli.

"I am frank to confess my ignorance in elucidating these studies at the present time because they resolve themselves into the use of almost inconceivable numbers of animals and a big organization. I am sure you realize what a big eye-opener Dr. Opie's studies have been concerning that so-called first infection which doesn't exist but is really repeated small infections.

"I might call your attention again to the stumbling block met by Koch in the original use of tuberculin. If this first infection and its expression in allergy were as significant as we thought, would Koch have fallen into the pitfall in his original studies when he advocated tuberculin as a therapeutic agent? Do not think me too critical of this entire consideration when I call your attention to the fact, that at the present time we are almost restricted to the use of mechanical procedures in our treatment of tuberculosis and the Calmette BCG vaccination is still hanging fire, yet what more ideal conditions could there be for demonstrating the significance of first infection than in the newborn infant?

"I am sure you could ramble on just as well as I in pointing out explanations and I can only close by saying that the future holds in store for us some striking surprises in so far as immunity in tuberculosis is concerned."

Dr. Allen K. Krause answered:

"It can easily and definitely be shown by experimentation that a first or preliminary infection of tubercle bacilli materially protects the recipient, that is, any type of animal susceptible to tuberculosis, against successive or secondary infection from without.

"There is every reason to believe that, everything else being equal (which of course it never is), a person exposed to tuberculous infection and receiving enough infection to be sensitized yet not showing active and progressive infection, is better able to cope with our present civilization, so far as tuberculous infection is concerned, than a person who has never been exposed to tuberculous infection."

Dr. Calmette of the Pasteur Institute replied as follows:

"Here is my answer to the question you have asked me. It is certain that a light primary infection not followed in a short time by a reinfection gives immunity. But if the primary infection is severe and followed by repeated reinfections, the primary infection becomes sensitive rather than protective.

"The necessity of a light infection (and moreover it must be as guarded as possible in case of the young child) is so evident in permitting the organism to resist outside infections that we definitely consider that in BCG vaccination with a living but avirulent bacillus and sufficiently attenuated to constitute an effective vaccine.

"The phenomenon of Koch concerns resistance of the organism relating to first infections and it is observed only in subjects whose primary infection is recent or when the primary infection has indicated a developing tuberculosis.

"I have explained all that in my book on the preventive vaccination of tuberculosis published by the Messon Publishing House, 120 Boulevard Street, Germain, Paris, VI, in 1928."

The determining factors involved in producing progressive and fatal disease or recovery appear to be the number of tubercle bacilli to the dose and the resistance of the host. The greater the dose, the more unfavorable the outcome. The resistance desired, if we are to accept the opinion of Rich and McCordock, is to have much immunity with little allergy: in other words, we want the immune forces to destroy the bacilli or localize their activities with as little local or general disturbance as possible. From the experimental work so far done it seems that this is best accomplished by a light primary infection and allowing a number of weeks time interval before being subjected to a reinfection. We realize of course that the perfect state would be eternal freedom from the tubercle bacillus, a non-infected body with no possibility of infection, but in our present civilization when at most any time we may be precipitated into a hot-bed of tuberculosis it does seem that a body fortified by a light infection stands the best chances of survival.

This opinion is further strengthened by the work of Dr. Lurie, at the Henry Phipps Institute,[11] which showed the fate of the tubercle bacillus in various organs of the body in both the infected and non-infected animal. The organs considered were the spleen, liver, lung, bone marrow and kidney. Dr. Lurie demonstrated that tubercle bacilli injected intravenously into non-infected rabbits were deposited in greatest number in the spleen, then in the liver, lungs, bone marrow and kidneys in the order given. They multiplied until the second to the fourth week when destruction of the tubercle bacilli by the body manifested itself. Destruction of the bacilli occurred in the spleen, liver and bone marrow, but they multiplied in the lungs and kidney until death. If and when recovery was the result, destruction of the bacilli also then took place in the lungs and kidney as well as the other organs beginning the second to fourth week. In the previously infected animal, the bacilli inoculated began to be destroyed immediately without preliminary multiplication.

The question naturally arises whether vaccination by attenuated tubercle bacilli such as Calmette recommends is a wise procedure. It is not well to dismiss this idea without careful thought. Workers such as doctors and nurses in particular who expose themselves to the hazards of tuberculous infection at some time or other in their lives involuntarily become vaccinated by the patients they serve. The tuberculin test becomes positive. Tubercle bacilli have gained entrance to the body in what numbers they know not. It might well be discussed whether the doctor or nurse who enters into a known source of infection should be vaccinated by the Calmette method or by the patient to doctor or nurse method. Whatever method is used it seems imperative that the possibility of a reinfection for a number of weeks should be guarded against. And so the doctor or nurse who in the course of treating the tuberculous patient develops a positive tuberculin test would perhaps be best safeguarded by a change of environment for a few weeks or months with plenty of rest, proper food and stimulating air and sunshine. As a substitute for the old adage, "Physician, know thyself," it might be well to say, "Physician, know thy vaccination."

ETHYLHYDROCUPREINE

Clinicians of large experience have grown skeptical about the use of ethylhydrocupreine (optochin) in the treatment of pneumonia, whereas they were once enthusiastic, and hopeful about its possibilities. In a review of this subject, Cahn-Bronner cites an extensive literature and concludes from his own experience and a review of numerous authors that ethylhydrocupreine is not superior to quinine and that neither drug is a specific in the treatment of pneumococcus pneumonia. The following with reference to ethylhydrocupreine appears in New and Non-official Remedies: "Clinical investigation indicates that the drug may be of value in the treatment of lobar pneumonia, if a sufficient amount can be administered sufficiently early without untoward effect. To avoid such effect it is proposed to secure low absorption through the administration of the free base by mouth. The hydrochloride may be administered intramuscularly, but is liable to be irritant. Intravenous administration seems to be contraindicated. The drug has a definite value in the treatment of pneumococcic infections of the eye (ulcus corneal serpens)." (Jour. A. M. A., March 22, 1930, p. 888.)

NO INTESTINAL ANTISEPTIC

There is really no such thing as an intestinal antiseptic, if that term is defined as equivalent to disinfectant, there being no known influence capable of killing the micro-organisms in the living intestine. If the term is defined to include inhibition of the growth and diminution in the number of intestinal microbes, then diet (milk diet in most adults) constitute perhaps the most important influence of that kind. Mild mercurous chloride might qualify as an efficient drug with a tendency in this direction. Phenolsulphonates (sulphocarbolates) are worthless. (Jour. A. M. A., June 14, 1930, p. 1939.)

POSSIBLE DEATH FROM DRINKING ETHYLENE CLYCOL ("PRESTONE")

A death is ascribed to drinking Prestone. Prestone is ethylene glycol. It is an excellent antifreeze agent for automobile radiators but a questionable beverage. Ethylene glycol has been introduced as a nontoxic substitute for benzene in lacquers and paints. There is no record of untoward effects from its proper use. Taken as a beverage, intoxication and death are reasonable expectations. (Jour. A. M. A., June 14, 1930, p. 1940.)

EVULSION OF THE PHRENIC NERVE FOR PULMONARY TUBERCULOSIS*

Everett K. Geer, M.D.
St. Paul

THE *sine qua non* in the treatment of pulmonary tuberculosis is, and until a specific remedy is found, will be, rest. It is so fundamental and withal so simple, so much so that not infrequently it becomes difficult to apply, that it seems pertinent from time to time to refresh our minds regarding its basic importance. And likewise it appears wise to accept and apply any measure or combination of measures which will insure more complete cessation of lung activity and to report and discuss concerning their virtues and deficiencies.

Artificial pneumothorax has found without question its rightful premier place in the accepted present day armamentarium for treating progressive unilateral tuberculosis of the lungs and in recurrent or ungovernable hemorrhage cases. Extrapleural thoracoplasty is as firmly established, particularly in handling the chronic excavated one-sided lesion, where pneumothorax has failed. These two measures have been used so univerally and over such a length of time that their therapeutic value is quite fixed and at a very high level.

Interruption of the function of the phrenic nerve is the third procedure which definitely affords pulmonary relaxation and compression and therefore more complete rest.

Simple section of the phrenic nerve, so-called phrenicotomy, was first suggested and used by Stuertz[1] in 1911. He recommended it chiefly for predominantly unilateral basal tuberculosis where pneumothorax was prevented by adhesions. Sauerbruch[2] in 1913 working quite independently of Stuertz reported five cases where phrenicotomy had been beneficial, noting particularly that no disturbance of heart action or respiration ensued. He also felt in combination with penumothorax that the possibility of effusion was diminished. Schepelmann[3] in 1913 suggested phrenicotomy for early lung tuberculosis. Some years elapsed with very little being done with phrenic nerve operations until 1921 when Goetze[4] and Felix[5] found that about 25 per cent of diaphragms were not immobile following simple sectioning of the nerve and attributed this failure to the presence of accessory fibers entering the main trunk line below the point of section. Each of them proposed a radical phrenicotomy to insure complete and permanent diaphragmatic paresis. Felix called his operation "phrenico-exairesis" and claimed that it resulted in a "marked curtailment of the respiratory activity of hemi-thorax and a diminution of the capacity of that side of the chest, causing a relaxation of the lung." Felix's operation is the one commonly used in this country today and consists practically of a complete evulsion of the nerve.

Since 1921 a rather voluminous literature on phrenicectomy has been produced with markedly varying opinions. H. Alexander[6] in 1922 felt that the chief benefit from radical phrenicectomy was on basal lesions though he noted that upper lobes were benefited also; he thought that the operation was indicated before every thoracoplasty and in testing the contralateral lung. O. Goetze[7] in 1922 felt that "every pneumothorax except that which gives extremely satisfactory results from the very beginning should be combined with a radical phrenicotomy." Frisch[8] in 1922 thought that phrenicectomy was useful in pneumothorax cases with adhesions and cited instances where hemoptysis was controlled by the combination where pneumothorax alone failed. Sauerbruch[9] in 1923 injected a more pessimistic note and warned that the hope which many expressed for phrenicectomy for healing progressive tuberculosis had not been realized. He noted that many were improved but none healed by the procedure and felt that it was of value primarily as an adjunct. Other continental workers agreed with this view such as Rolland, Maurer and Volter[10] (1924), who concluded that immediate results were good but final not so good. Lehmann[11] in 1924 felt that the value of phrenicectomy depended on its combination with pneumothorax or thoracoplasty and held the opinion that exudative lesions do not respond well. Hauke[12] in 1924

*Presented before the Minnesota Academy of Medicine, Saint Paul, October 9, 1929.

noted that the part played by the diaphragm in respiratory widening of the thorax is not significant and that artificial paralysis of the diaphragm did not cause disturbance of respiration or circulation and that it did favor expectoration rather than inhibit in. He reported two failures in twenty-four cases. Laudgrof[13] in 1924 thought that phrenicectomy was indicated in: (1) severe pulmonary tuberculosis where one side was so advanced that pneumothorax or thoracoplasty was not permissible; (2) in bilateral disease not too extensive; and (3) in apical lesions when progressive but not pneumonic. He had had two persons with lower lobe tuberculosis who lost their sputum and bacilli following phrenicectomy. J. Alexander[14] in 1924 made a plea for radical phrenicotomy in the treatment of early pulmonary tuberculosis arguing that "the decidedly favorable influence of the pulmonary rest and relaxation caused by complete paralysis of a hemidiaphragm in advanced tuberculosis strongly supports the suggestion that radical phrenicotomy in conjunction with the usual careful hygienic regime, would offer patients with predominantly unilateral early tuberculosis, who are not making satisfactory progress under the hygienic regime alone, a greater chance of early and permanent clinical cure than any other known method of treatment." As far as I can determine, this suggestion of Alexander has never had a thorough trial though it has distinct merit. Gravesen[15] in 1925 in his monograph on the surgical treatment of pulmonary tuberculosis devoted but little space to phrenicectomy and said it should as a rule be used in conjunction with pneumothorax and thoracoplasty; that more rarely it alone may be of benefit. Lilienthal[16] in 1925 stated that phrenicectomy is often of great therapeutic value in pulmonary tuberculosis and other disorders. At that time he apparently had had a very small experience with the procedure. He mentioned its use for diaphragmatic pleuritic pain. Alexander[17] in his "Surgery of Pulmonary Tuberculosis" (1925) devoted a very satisfactory chapter to phrenicectomy. His indications for its use were when used independently: (1) In acute tuberculosis where the pleura is adherent and thoracoplasty contraindicated; (2) in chronic disease with adherent pleura and with poor general condition and other lung not good; (3) in moderately or far advanced cases where pneumothorax or thoracoplasty are not contraindicated

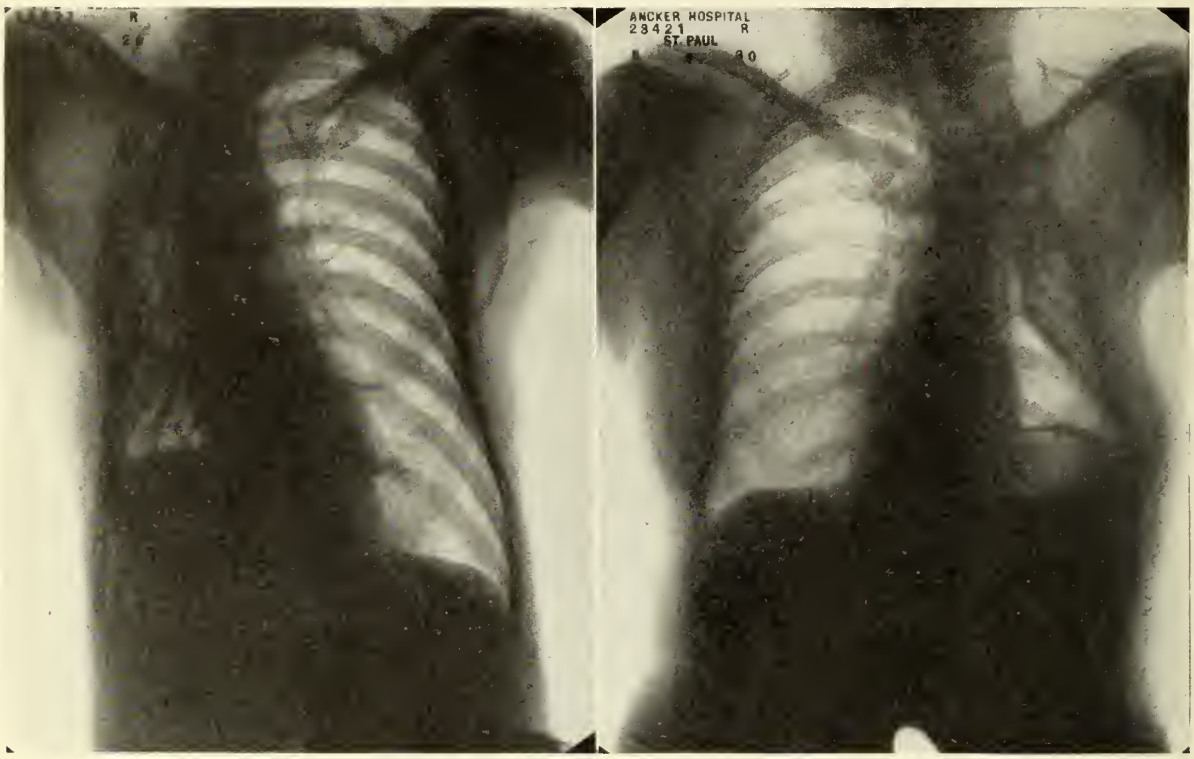

Fig. 1. Phrenic nerve evulsion with complete and upper rib thoracoplasty.

and where it might get away from pneumothorax refills or the hazards of thoracoplasty; (4) for early cases which do not show sufficient improvement with the usual sanatorium regime. As an adjunct to pneumothorax he recommended its use: (1) when partial or total pneumothorax was not producing satisfactory results; (2) supplementary to satisfactory pneumothorax in order to cut down the frequency of refills, to help reduce the incidence of effusions and to reduce the degree of expansion. He further stated that it is rapidly gaining favor as an operation to be performed before every thoracoplasty. Alexander did not mention its use for unilateral basal lesions and stressed the virtue of phrenicectomy as an adjunct remedy rather than use alone and urged no waiting period after but more surgery such as thoracoplasty at once. Bacmeister[18] in 1926 reported eighty cases in which phrenicectomy was used and concluded it was suitable and valuable as an adjunct. Moreau and Olbrecht[19] in 1926 held the opinion that the ideal theoretical indication was in a lesion limited to one base and thought in this instance phrenicectomy was preferable to pneumothorax. Berard, Guilleminet and Desjacques[20] in 1927, after reviewing results in fifty-one cases, concluded that pneumothorax and thoracoplasty remain the great means of pulmonary collapse and that phrenicectomy is a supplementary resource not to be underestimated or neglected. Wolf and Lossen[21] in 1927 noted obliteration of a cavity after phrenicectomy. Geer[22] in 1927 advocated its use preliminary to thoracoplasty and cited four cases of basal lesions which had been improved markedly following phrenicectomy. Matson[23] in 1927 noted improvement in upper lobe cavities following phrenicectomy and urged its routine use preliminary to every thoracoplasty. He also felt it was of value in conjunction with partial pneumothoraces, and because of its simplicity and great value thought that phrenicectomy must be considered next after pneumothorax and before other radical procedures. He stated "as a simple procedure in selected cases and as a supporting operation we are convinced of the value of phrenicectomy." Davies[24] in 1928 said that phrenicectomy was a great help in handling basal lesions and that it always should be done in long standing pneumothorax cases before expansion. Lord[25] in 1928 stated that phrenicectomy "still holds a place among measures designed to assist in putting a tuberculous lung at rest, but that it is of relatively little value as an independent procedure but

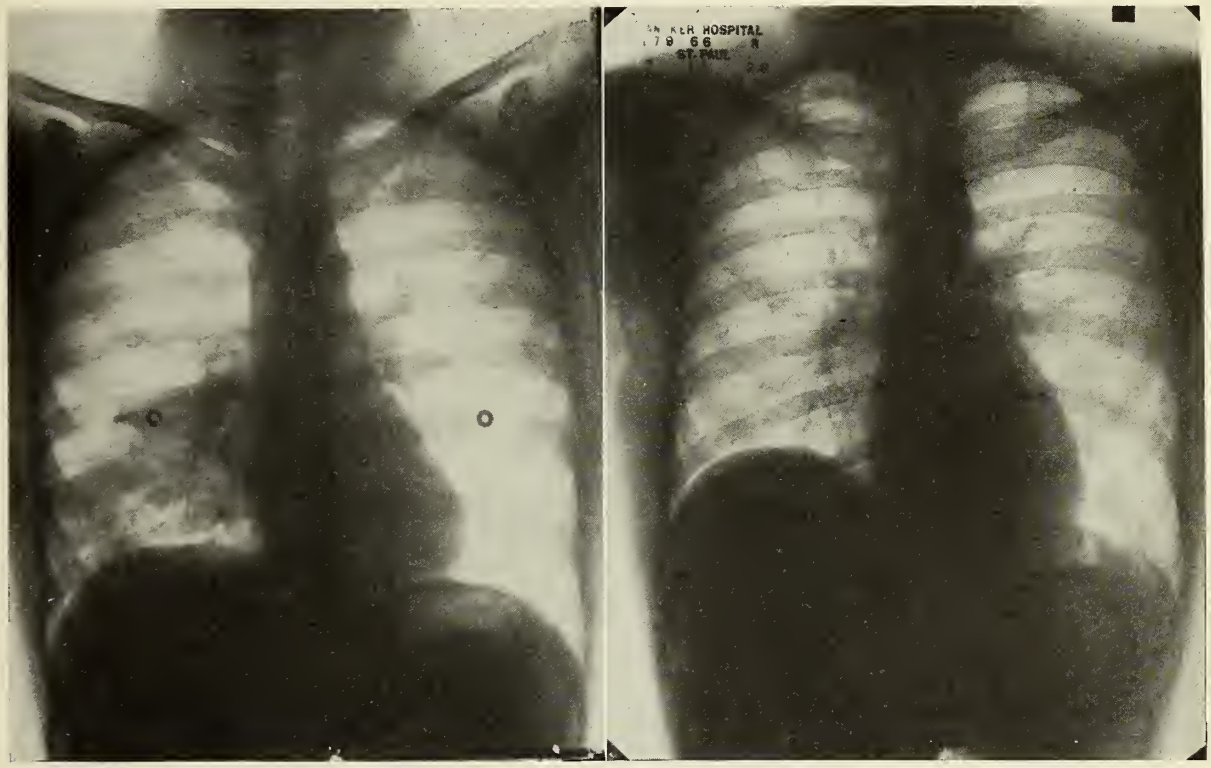

Fig. 2. Phrenic nerve evulsion for lower lobe tuberculosis. Note resolution of right lower lobe lesion after phrenicectomy.

it may serve to estimate the capacity of the opposite lung when that is uncertain or as a preliminary to a more radical operation and that it is to be regarded as of limited therapeutic and fect upon upper as upon lower lobe lesions and that it was of no help as an adjunct to pneumothorax.

The anatomy of the phrenic nerve is worthy of

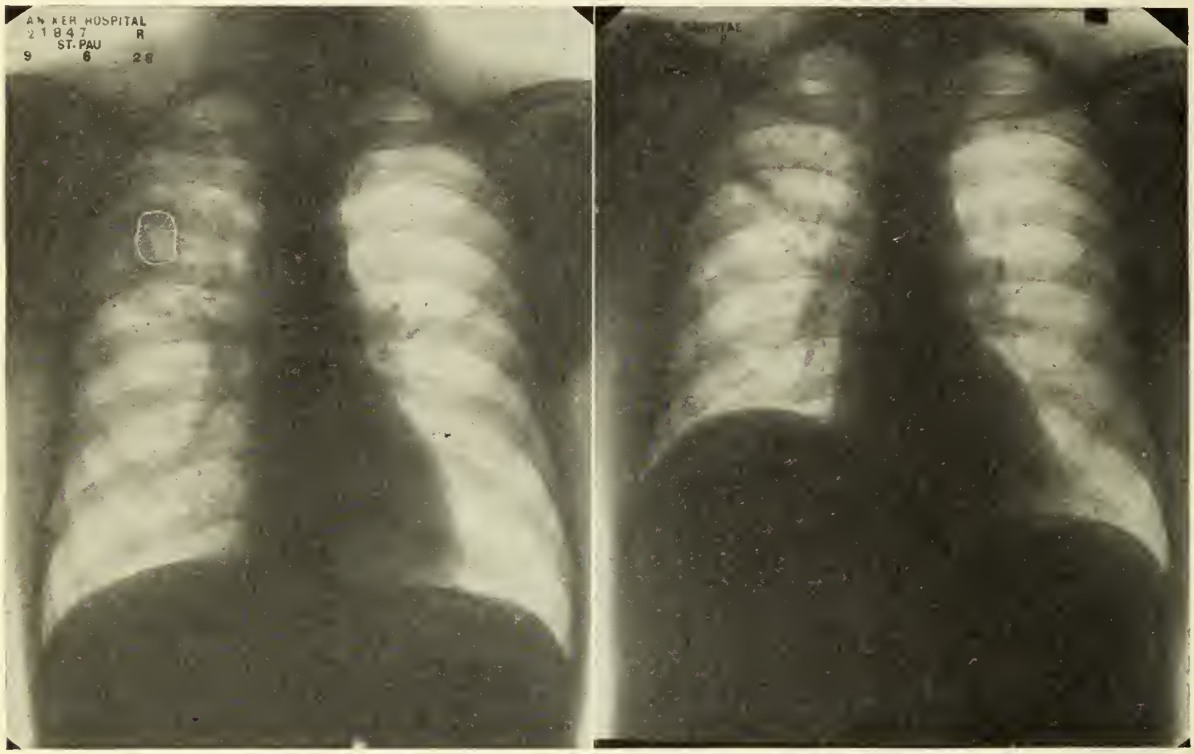

Fig. 3. Phrenic nerve evulsion for upper lobe cavity. Note obliteration of right upper lobe cavity after phrenicectomy.

diagnostic value when used alone." Mayer and Leitch[26] in 1929 report cases in which upper lobe cavities of over three centimeters in diameter closed following phrenicectomy. They noted that at times a diaphragm apparently adherent fluoroscopically will rise after phrenicectomy. Loewenthal[27] in 1929 reported five cases in which pneumonia developed after phrenicectomy and thought this was due to lack of proper aeration due to immobility of the lung. Holmboe[28] in 1929 on the other hand thought phrenicectomy should be given a trial because it is free from danger and in many cases undoubtedly gives good results. Matson[33] contended in 1929 that evulsion of the phrenic nerve was indicated as an independent procedure in those cases wherein a thoracoplasty is impossible and as a preliminary to every thoracoplasty. Wells[34] in discussing the results of three hundred phrenicectomies in 1929 felt that it is valuable in a wide variety of pulmonary tuberculosis cases. He found it had as much ef-

brief review. It takes origin from the third, fourth and fifth cervical roots, with occasional fibers from the seventh and eighth cervical and first thoracic. Its main trunk is in association with a small ascending cervical artery for a short distance and runs beneath the sternocleidomastoid muscle downward and inward across the anterior surface of the scalenus anticus muscle, thence beneath the subclavian vein into the thorax along the external surface of the pericardium to the diaphragm. Goetze could demonstrate no anastomosis between the right and left phrenic nerves. Felix could not show any connection between the vagus and phrenic nerves. In about 25 per cent of people there is an accessory phrenic nerve arising from the fifth cervical, sometimes according to Felix from the third, fourth or sixth. The phrenic nerve according to Felix supplies the entire motor innervation of the diaphragm except for a few fibers that arise from the twelfth intercostal nerves. Lemon[29] concluded that if the dia-

phragm receives any innervation from the intercostal nerves their usefulness is so small that it is inadequate to prevent atrophy or to permit of contraction when the nerve is stimulated. Matson[30] in dissecting out one hundred and twelve phrenic nerves on cadavers found only 72 per cent typically situated. He found double phrenics with associated fibers on the face of the scalenus anticus eight times. In four instances associate phrenics came from the subclavian nerve. Once he found a bilateral and once a unilateral absence of the typical phrenic nerve, there being no main trunk on the anterior surface of the scalenus anticus, but two large trunks coming mostly from the fifth cervical close to the point of origin of the subclavian nerve. All three of these passed down in front of the subclavian vein and came off so far lateralwards that they could not be located by the customary incision. In twenty-three instances the accessory phrenic fibers came in common with the subclavian nerve from the fifth cervical root. Six times the accessory nerve was apart from the subclavian nerve as a separate branch. In five other instances it formed a loop around the vein. Once two associate phrenic trunks passed in front of the subclavian vein, then looped around behind the internal mammary artery. In one instance he found the associate phrenic passing through the wall of the subclavian vein. Because of these anatomical variations, Matson felt that the Felix type of radical phrenicotomy is not without danger.

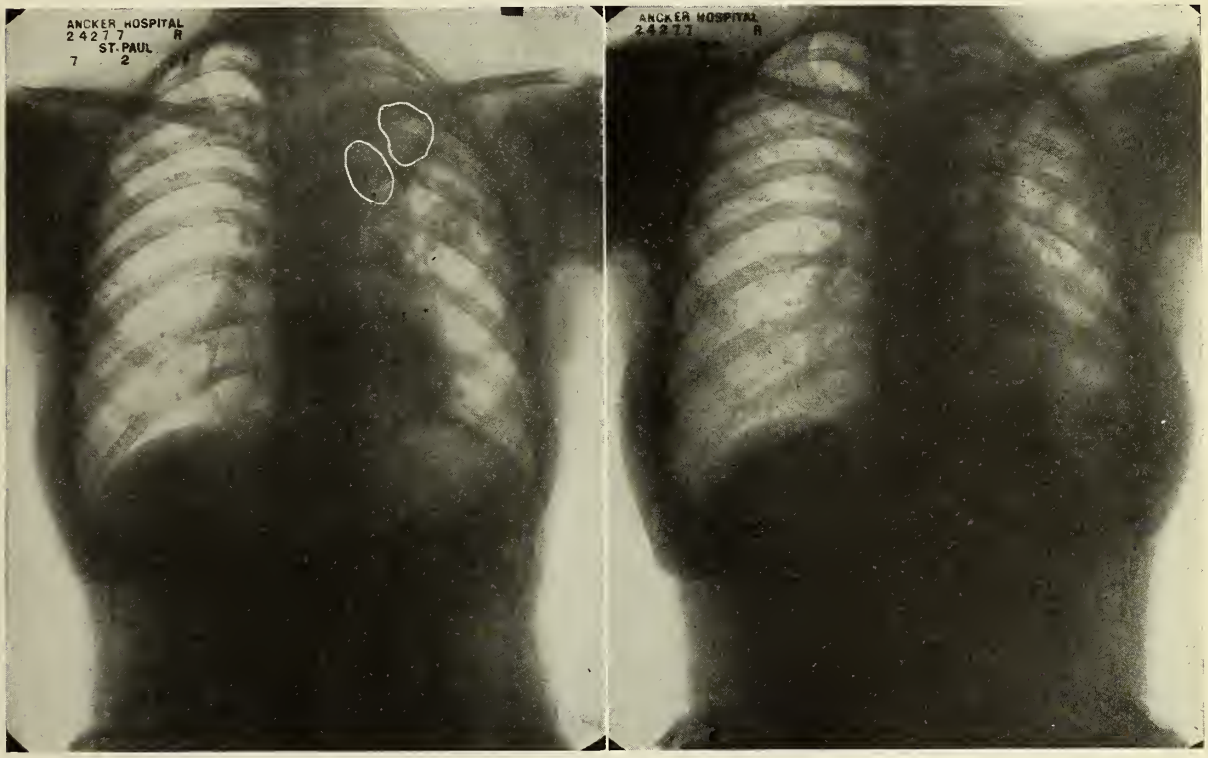

Fig. 4. Phrenic nerve evulsion for upper lobe cavitation. Note closure of two cavities in left upper lobe after phrenicectomy.

The effect of a unilateral phrenicectomy in a person with a non-adherent diaphragm is a complete paralysis and a passive rise of the hemidiaphragm into the chest to a full expiratory position. Several months may elapse before it attains its ultimate position. It may not be completely immobile due to tugging of the central tendon by the normally active side or to the so-called paradoxical movement effected by intra-abdominal pressure. The reduction of lung volume by phrenicectomy varies between 25 and 35 per cent. The pulmonary relaxation subsequent to phrenicectomy and the reduction in lung volume affords a certain amount of rest though the elimination of the pumping or piston-like action of the diaphragm is the most important single factor resulting from the operation. This affects chiefly the lower but also the upper lobes. Brunner[31] found a right lung of 2400 c.c. volume reduced 600 to 900 c.c. by thoracoplasty and that it was

reduced 400 to 800 c.c. by phrenicectomy. He further noted that cough and expectoration were easier after phrenicectomy. In other words, the anatomical and physiological effects of phrenic nerve interruption are similar to thoracoplasty though less marked.

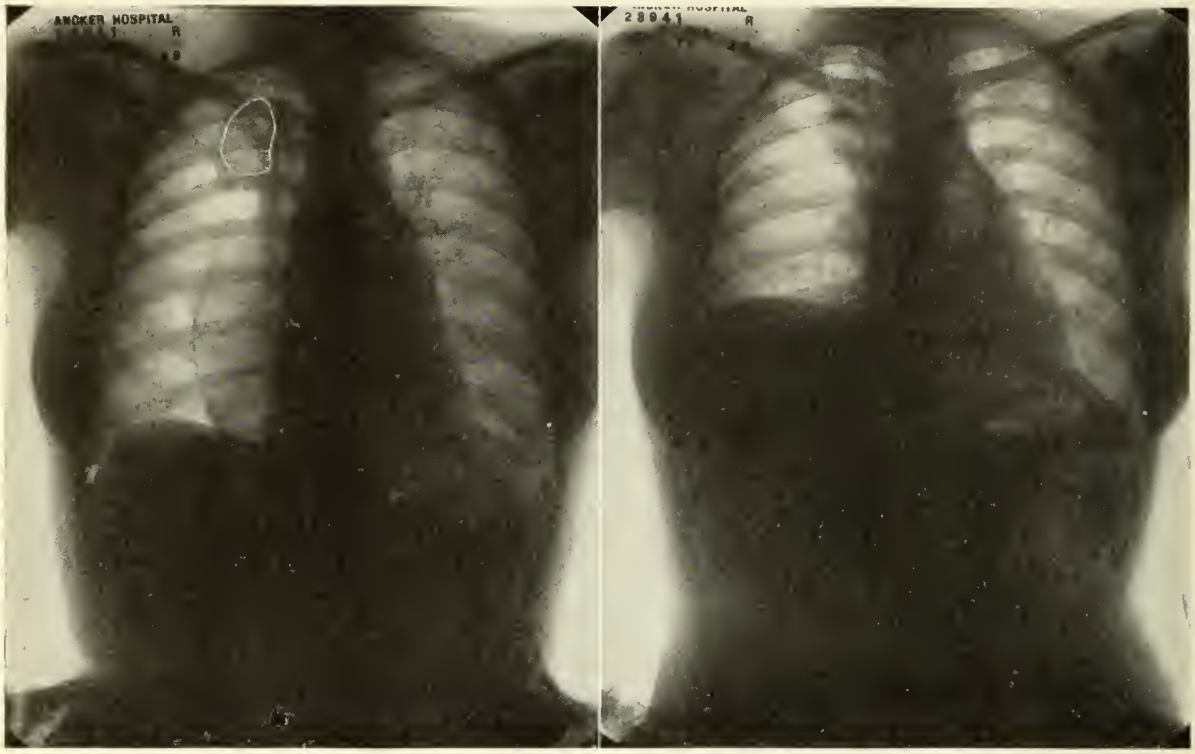

Fig. 5. Phrenic nerve evulsion adjunct to pneumothorax. Cavity held open by adhesions which closed after phrenicectomy.

Lemon[29] observed experimentally that section of one phrenic nerve caused paralysis and atrophy of the entire hemi-diaphragm on the same side and that after five months there was no evidence of cross innervation or regeneration. He further felt after observing the effects of both unilateral and bilateral phrenic neurectomy in dogs that perhaps the functional importance of the diaphragm had been overestimated.

It is obvious that the height to which the diaphragm rises after phrenicectomy and the beneficial results obtained are closely related. This factor is one which cannot be foretold and one which will be fully known only after several months have elapsed. Alexander found the average elevation of the paralyzed diaphragm in twenty cases, including right and left, to be 7 cm. at the end of inspiration and 3 cm. at the end of expiration. Most authors have found that the right diaphragm rises higher than the left but my experience has been the reverse.

I know of no case where bilateral phrenic nerve evulsion has been done for pulmonary tuberculosis. Sauerbruch has performed the operation for persistent singultus on both sides with only temporary dyspnea; Wells has done the same thing. Lemon has done it experimentally on dogs with no apparent ill effect. In one of my cases, that of a woman with a basal lesion, the diaphragm on the opposite side was completely immobile because of adhesions. Following phrenicectomy she was quite comfortable with two fixed diaphragms and now, three years after, is alive and well.

My experience in using phrenic nerve evulsion in the treatment of pulmonary tuberculosis is limited to ninety-three cases from the Pokegama Sanatorium and the Ancker Hospital Tuberculosis Pavilion. Twenty-eight were in combination with extrapleural thoracoplasty, fifteen of these with the complete thoracoplasty operation, and thirteen in combination with resection of the upper five to eight ribs. It is difficult to correctly evaluate the value of phrenicectomy

used in this manner. To me it seems the logical procedure and I unhesitatingly urge the operation preliminary to every thoracoplasty for the reason that the capacity of the lung to be operated upon is reduced thereby from 400 to 800 c.c. This, of course, gives more lung relaxation and therefore more effective compression and more rest. Furthermore our experience[32] in studying unsuccessful thoracoplasty cases with the aid of iodized oil has shown that a certain percentage of chronic fibroid lungs have varying degrees of bronchiectasis which calls for the most complete collapse possible in order to check cough and sputum.

Forty-five of my series were done on persons with upper lobe cavities in whom there was such a definite tendency for the cavities to close after phrenic neurectomy that thoracoplasty was withheld to see what would happen eventually. Twelve of these achieved complete obliteration of their cavities with resultant loss of bacillary sputum. Two others apparently did the same thing within two months, only to have symptoms later with reopening of the cavities. Fifteen have been done too recently to judge results but at this time do not look encouraging. One with an unusually large cavity was allowed to go eight months because of the extraordinary reduction in the size of the cavity but finally was submitted to an upper lobe thoracoplasty with success.

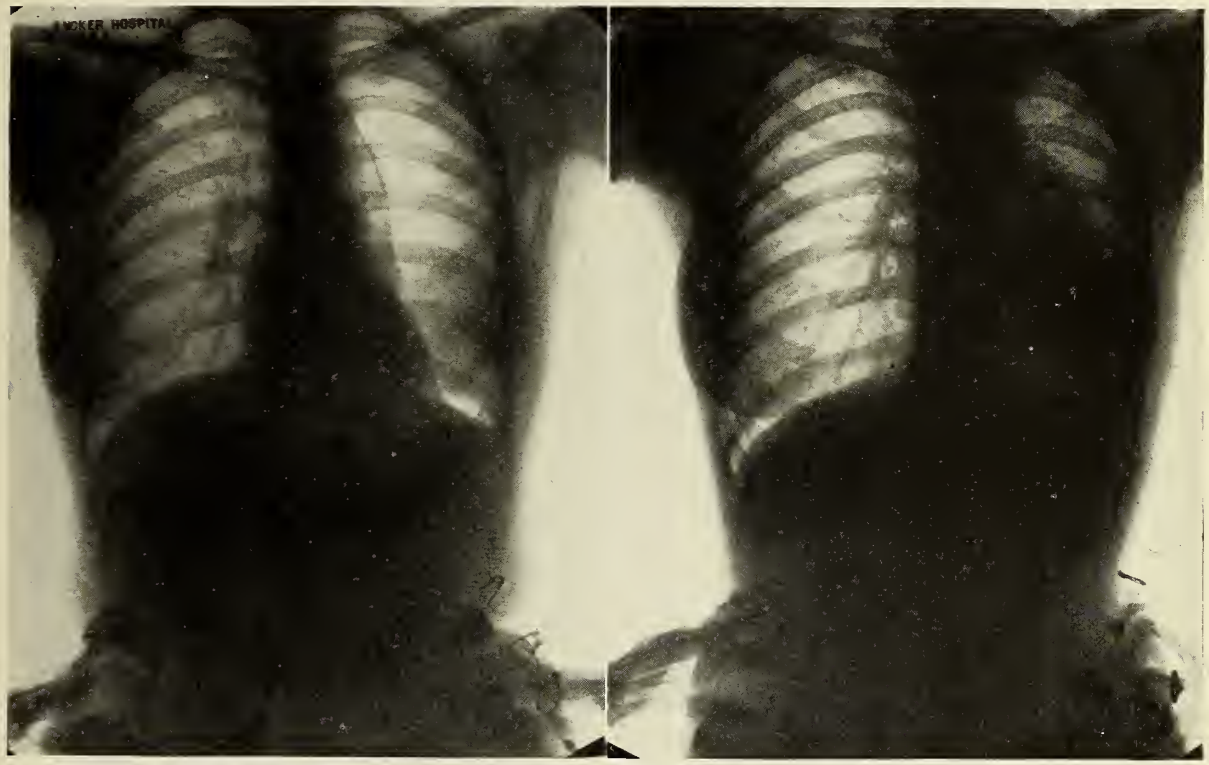

Fig. 6.—Phrenic nerve evulsion with expansion after pneumothorax for five years. Note reduction capacity of left hemithorax rendering complete expansion impossible.

Ten patients with unilateral basal lesions have submitted to phrenic nerve evulsion. Five are clinically well. One died of generalized tuberculosis. Another has been done so recently as to be uncertain as to its outcome. One other had a normally moving diaphragm following the operation but did well with eighteen months' bed rest. Thoracoplasty and pneumothorax were necessary in the other two cases.

Thirteen phrenicectomies have been done in conjunction with pneumothorax. One of these had an upper lobe cavity held open by adhesions; with phrenicectomy sufficient additional relaxation was afforded so as to obliterate the cavity. Three have been done preparatory to permitting the lung to expand. One of these was an original upper lobe lesion with a bronchogenic spread into the lower lobe on the same side. A perfect result was obtained with pneumothorax and on allowing the lung to partially expand it was noted that the upper lobe was quite clear and expansile, but that the lower lobe was ap-

parently non-expansile. After phrenicectomy the upper lobe expanded completely, filling the thoracic space but leaving the lower lobe collapsed. The fifth pneumothorax case was one of lower lobe cavitation incompletely closed by air and which did close following phrenicectomy. The sixth was done because of premature expansion caused by an obliterating pleuritis subsequent to an effusion. In this case phrenicectomy was not successful in preventing reopening of upper lobe cavities and the patient has undergone an extrapleural thoracoplasty. Seven others had upper lobe cavities held open by adhesions and were uninfluenced by phrenicectomy.

One case was that done in a patient with a five centimeter cavity close to the left root and in whom a dense shadow behind the heart suggested bronchiectasis. An intratracheal iodized oil injection proved a lower lobe bronchiectasis and phrenicectomy was done hoping the bronchiectasis would be benefited. Her cavity and bronchiectasis continued on their way unaffected. In one instance phrenic nerve evulsion was done for a fulminating lesion where pneumothorax could not be induced because of adhesions and thoracoplasty was contraindicated; death ensued despite the phrenicectomy.

Six patients in this series of ninety-three continued to have normal diaphragmatic movement following the operation. In two of these no nerve could be found which, when stimulated, caused diaphragmatic contraction. Two probably had deep accessory fibers. Second operations in the other two were successful in finding and evulsing the nerve.

To summarize: I feel that phrenic nerve evulsion should precede every thoracoplasty operation for pulmonary tuberculosis, as it does afford increased pulmonary relaxation. Some workers feel that aspiration episodes are more likely to follow if phrenicectomy is done first but I have yet to see it happen. And, furthermore, it certainly is true that the nerve can be found more readily before thoracoplasty than after because apparently the dropping of the first rib alters the cervical anatomy. I am convinced that phrenicectomy alone in a high percentage of one-sided basal lesions holds out opportunity for an excellent clinical result and believe that it warrants primary trial here unless the lesion is a fulminating one, in which case pneumothorax is the treatment of choice. It is also quite apparent that a certain number of upper lobe cavities will close with phrenicectomy and I, therefore, disagree with Alexander, Sauerbruch, and others who feel that all phrenicectomies should be immediately followed by thoracoplasty. A few months' waiting period unquestionably will save from 20 to 30 per cent of these people further operative interference. Its use in conjunction with pneumothorax is rational, especially when used preliminary to re-expansion. Furthermore, it seems wise to employ it in those pneumothorax cases where adhesions are preventing a satisfactory collapse before resorting to more radical measures such as pneumolysis, opened or closed, or thoracoplasty, although in this field it apparently is the least helpful.

In conclusion I would state that:

1. Phrenic nerve evulsion is the third most valuable means we have for effecting more complete lung rest than bed rest alone affords.
2. It should be employed preliminary to every extrapleural thoracoplasty done for pulmonary tuberculosis irrespective of diaphragmatic adhesions.
3. It is particularly efficacious alone when used for unilateral lower lobe tuberculosis.
4. It will succeed in obliterating a certain number of upper lobe cavities.
5. It can be used to advantage in combination with pneumothorax especially in cases with adhesions and prior to re-expansion.
6. It is well to emphasize that phrenic nerve evulsion is no overnight cure for pulmonary tuberculosis, nor anything remotely approaching it. A carefully supervised sanatorium regimen is just as important with as without the operation and this point cannot be overstressed.

NOTE: My grateful appreciation is due Drs. A. R. Colvin, L. E. Daugherty, D. G. Gardiner and E. M. Jones, who have done the operating on the above cited cases and who at all times exhibited an indispensable spirit of coöperation.

THE CUTANEOUS ABSORPTION OF MERCURY

It requires little imagination to appreciate the uncertainties that must attend the problem of dosage when such a relatively insoluble substance as mercury is applied to the skin. The size of the particles, the nature of the adjuvant, the place of application and its conditions, and the vigor with which inunction is practiced are some of the complicating features. The assumption that only the mercury globules rubbed into the follicles are gradually absorbed had led to the clean inunction method proposed by Cole and his collaborators. Some indication of the efficacy of inunction procedures can be secured by estimation of the substance that is eliminated. This has been done and it was found that the amount of mercury which is absorbed and excreted after inunction is dependent directly on the concentration of the metal in the base—that is, 5, 25 and 50 per cent preparations show that the excretion is about in proportion to the concentration in the ointment used. Again, contrary to what many have assumed, colloidal mercury ointments showed no greater excretion of mercury than official old fashioned mercury ointments of equal concentration in benzoinated lard. Furthermore, massive or intensive weekly inunctions of a 30 per cent mercurial ointment may lead to an equal or higher mercury excretion than the simple daily use of 50 per cent ointment or even certain types of intramuscular injection. (Jour. A. M. A., April 26, 1930, p. 1322.)

PRESIDENT HOOVER SIGNS BILL CREATING NATIONAL INSTITUTE OF HEALTH

Recently President Hoover signed a bill sponsored by Senator Ransdell of Louisiana, which provides that the Hygienic Laboratory of the United States Public Health Service shall become the national institute of health.

In a recent radio broadcast, an authorized summary of which was published in the *United States Daily*, Senator Ransdell stated:

"The most important feature of the bill is the provision for fellowships, which would be in the nature of chairs, as those chairs are founded in institutions. The most valuable asset of the people of the country is brains. There are young men who, by reason of lack of finances and lack of encouragement, and the inaccessibility of a scientific environment in which to develop, have fallen by the wayside.

"The purpose of a measure of this kind is to have potentially available a provision whereby a young man could be aided, not for a few days or a few weeks to finish his education, but to aid him after he has graduated, providing he is an extraordinary student. I contemplate that nobody but outstanding students will receive consideration under this act, and their first duties would be to come to the national institute of health and receive their training and stimulus, and then be subject to detail wherever health problems might be desired to be taken up."

—*Health News*, June 30, 1930.

THE TREATMENT OF BOILS AND CARBUNCLES BY ROENTGEN RAYS*

EUGENE T. LEDDY, M.D., and S. ARCHIBALD MORTON, M.D.
Rochester, Minnesota

A CARBUNCLE may be regarded as an aggregation of boils and may be a much more serious condition than a boil. The same methods of treatment are used for both.

The usual methods of treatment are hot poultices, incision, local application of ointments and lotions, administration of drugs internally, and vaccines. Those methods of which the purpose is abortion of the process are often not effective; the abscess continues to form, and later breaks down or is incised, leaving a discharging wound that takes a varying length of time to heal. The infective discharges are likely to cause similar lesions nearby.

Hot poultices are to be condemned because of their aptitude for spreading the infection to adjacent hair follicles. Although they frequently relieve the pain, the patient must curtail his activities more or less while they are being used. Incision is often necessary, but it is to be avoided whenever possible as it makes a discharging sore which may heal slowly, leaving an ugly scar. Ointments and lotions are messy and seldom of much value in aborting the disease. Drugs given by mouth, particularly the preparations of sulphur and tin, are recommended by some, but opinions as to their value vary. The vaccines used are either of the stock or autogenous variety. They are useful only in cases of recurring boils, and the autogenous variety has the further disadvantage that it takes some days to prepare it. The vaccine treatment, to be of value, must be given over a period of several weeks or months and, in addition, is expensive.

In spite of the fact that roentgen rays have been used successfully in the treatment of boils and carbuncles for more than twenty years, the value of the method apparently is not appreciated by most physicians. We believe that the treatment of these lesions by roentgen rays, although not always efficacious, is superior to the methods generally used.

When the process is in the indurated state, before it has "come to a head" and before it is discharging, treatment by roentgen rays causes rapid regression in about half of the cases and considerable relief in the remainder. When a core has formed, or when the sore is discharging, not as much can be expected from treatment. However, in most cases, besides shortening of the duration of the disease, definite analgesia is brought about, which is much appreciated by the patient. If the patient is having successive boils in a given region, roentgen rays will prevent infection of other follicles. We have never seen a new boil develop inside the field irradiated.

TABLE 1

COMPARISON OF RESULTS IN EARLY AND LATE TREATMENT OF BOILS AND CARBUNCLES BY ROENTGEN RAYS

Result	Treated in less than three days from onset, 44 cases	Treated in more than three days from onset, 56 cases
Analgesia	43	50
Abortion	28	....
Prompt improvement	10	8
Slow improvement	2	42
Failure	4	6

In order to evaluate the treatment, we reviewed the histories of 100 cases in which we knew the outcome of the disease. These comprised seventy-four cases of boils and twenty-six cases of carbuncles. For the roentgenologic treatment to be of maximal value, it should be given early in the course of the disease (Table 1). We considered that we had aborted the lesion when it disappeared in two days or less, and that the treatment was a failure if the extent and duration of the process were not appreciably shortened, even though considerable analgesia might have been obtained.

When the lesions were treated early, they were in the stage of induration. Comparison of the results on the basis of whether induration or

*From the Section on Therapeutic Radiology, The Mayo Clinic, Rochester, Minnesota. Submitted for publication June 3, 1930.

actual suppuration was present is shown in Table 2.

As would be expected, boils respond more favorably to treatment than carbuncles (Table 3).

TABLE 2

RESULTS OF TREATMENT OF BOILS AND CARBUNCLES BY ROENTGEN RAYS WHEN INDURATION WAS PRESENT COMPARED WITH RESULTS WHEN SUPPURATION WAS PRESENT

Result	Induration present, 58 cases	Suppuration present, 42 cases
Analgesia	54	39
Abortion	28	....
Prompt improvement	15	3
Slow improvement	11	33
Failure	4	6

The technic used in these cases varied according to the stage and extent of the disease. Specifications of dosage for a typical boil were as follows: 135 kilovolts; 4 mm. aluminum filter; 16-inch distance; 5 milliamperes; ten minutes. Carbuncles were given a higher dose (same factors for fifteen to eighteen minutes). Care was taken that the field was wide enough to include all of the diseased tissue. If the removal of the surrounding hair was necessary to prevent infection of the other follicles, an epilatory dose was used. Specifications for this dose were as follows: 80 kilovolts; no filter; 16-inch distance; 6 milliamperes; five minutes. This was used also in the treatment of folliculitis. We have not found it necessary to repeat irradiation of a boil.

COMMENT

It is well known that the lymphocytes are the most radiosensitive cells in the body, and that destruction of lymphocytes is one of the first effects noted following exposure to moderate doses of radiation. It is important, in this connection, to emphasize that in treating inflammatory lesions, large doses of roentgen rays are neither necessary nor advisable because of the great sensitivity of these inflammatory cells.

The mechanism of the effect is not perfectly understood. A plausible explanation is this: Since it is known that small round cells act as a defense against pyogenic infection, and that lymphocytes are extremely sensitive to radiation, it is fair to assume that when these cells in an inflammatory lesion are destroyed, the protective substances in them are liberated in larger amounts for immediate defense than is the case when they remain intact. This theory at least is in accord with known clinical facts.

TABLE 3

RESULTS OF TREATMENT OF BOILS BY ROENTGEN RAYS, COMPARED WITH RESULTS OF TREATMENT OF CARBUNCLES

Result	Boils, 74 cases	Carbuncles, 26 cases
Analgesia	58	25
Abortion	26	2
Prompt improvement	14	4
Slow improvement	30	14
Failure	4	6

There are several advantages in the use of roentgen rays in these conditions. The treatment can do no harm. It is painless and inexpensive, does not consume much time of either the patient or the physician, and is almost always effective. Another advantage is that in the early stages in which other methods offer least, roentgen rays are of most value. If a patient comes with an indurated swelling, suggesting an early boil, the physician has nothing that he can use that will abort the disease. If the indurated type of lesion is treated with roentgen rays, not only are all dressings and infected discharges obviated, but rapid, marked benefit should ensue in more than 80 per cent of the cases, and the lesions should heal without scars.

The disadvantage of this form of treatment is that the facilities for giving it are available only in the larger centers. However, a boil, and particularly a carbuncle, is a debilitating enough condition to warrant the sending of the patient to a place where he can be adequately treated by a method that gives him the best chance for prompt relief.

CONCLUSION

We believe that the treatment of boils and carbuncles in the early stage by roentgen rays is the best at the present time and that it should be utilized more frequently.

SOME OBSERVATIONS ON THE ETIOLOGY OF TIC DOULOUREUX WITH THE CLINICAL REPORTS OF A NEW METHOD OF TREATMENT*

Charles R. Ball, B.A., M.D.
Saint Paul

At the time of our first presentation of the treatment of tic douloureux by the method of alcohol injection, some one objected to this plan of treatment on the ground that it was unscientific, for it only stopped the pain but it did not cure the disease.

At the time, this objection seemed rather trivial to us, because with the majority of the patients, when their pain was relieved they instantly declared themselves to feel perfectly well, and proved their assertion by returning at once to their customary activities.

As our experience increased with this form of treatment this objection, which seemed unimportant at the time, began to interest us more and more. One could, of course, make the same objection with reference to any other nervous condition, such as epilepsy, migraine, asthma, hives, etc. As soon as their attacks stop, the patients are to all visible appearances entirely well.

There were, however, always a few, indeed a very few—to use a political expression—who made up a troublesome minority. This minority after an apparently successful injection, and by successful we mean an injection which produced anesthesia in the entire area of the distribution of the branch of the nerve injected, while their severe pain was relieved, still complained of various annoying sensations in this area of anesthesia. These sensations differed greatly in description if not essentially in character, because they could all be classified under the title of paresthesias. In some the complaint was simply of the numbness which the injection had caused. In others the sensations were described as of a burning, creeping, crawling, pulling, drawing, pressing nature. They also varied in intensity of complaint as much as they did in the variety of their description. In some they were merely casually mentioned when the patients were asked about their faces. In others they seemed so distressing that the patients made almost constant complaint of them, and occasionally a patient would say these sensations had caused him even more suffering than his neuralgic pain had done.

All of us know very well the tendency of a patient, no matter what symptoms they have had before taking, so to speak, to date everything after taking, not to some change in the character of their symptoms or any constitutional weakness in themselves, but to the method of therapy, whether of a medicative or surgical nature. And so these patients were only following the general rule of human nature when they attributed as the cause of their subsequent discomfort the effects of the alcohol on the nerve injected, whether rightly or wrongly, since the paresthesias occurred usually in the nerve injected.

Looking at the matter from the patient's angle it was easy to see the justification for their way of thinking. These paresthesias occurred mostly in the area of distribution of the nerve injected.

The area supplied by other branches remained comparatively free. Our first thought was also to accept the patients' reason and consider a perverse or insufficient reaction of the nerve to the alcohol as the most likely cause. But with further consideration and experience with these paresthesias it was quite evident that other probable sources should not be ignored.

We know quite well that oftentimes, especially in a fundamentally functional nervous patient, one clinical syndrome as the result of treatment is transformed into what seems to the patient something else entirely different.

As an illustration, we have frequently observed a quite definite transformation in epileptics as the result of treatment, the epileptic attack either being greatly modified in character, or even taking on a migrainous character. Then the patients, ignoring the fact that their epilepsy had disappeared, would return complaining that our medication had given them headaches which they did not have before. Only the other day we had a patient with narcolepsy in whom the first

*Presented at a meeting of the Ramsey County Medical Society, at St. Paul, Minnesota, April 28, 1930.

reaction to the treatment was a change in the clinical picture from that of the sleeping attack to one of a quite severe nausea. Naturally, this patient as well as his family placed the blame for the nausea on the medication.

If these paresthesias had only occurred in patients who had received injections of alcohol we might still be attributing the cause to alcohol.

It was soon brought to our observation that patients who were surgically treated and never had received an alcoholic injection also were subject to the same distressing paresthesias.

Frazier reported in 1925 ten surgical patients who suffered severely after their operation from similar symptoms. Of this series he at that time says the sensory root operation in five instances had been performed and in all but one of these no doubt there had been an error in diagnosis. The patients did not have trigeminal neuralgia.

Because we feel that such patients aid very materially in broadening our conception of the etiology of this type of neuralgia we will cite his report on one of them. This case was operated on March 23, 1916 (section of the sensory root). Some features of the neuralgia were atypical but others seemed sufficiently characteristic to justify the major operation. Course, March 7, 1917 (almost a year later): Following operation the patient complained bitterly of a burning, throbbing sensation in the upper and lower alveolar processes and in the molar region. These disturbing sensations continued day and night without intervals of relief, and on one occasion it was noted that there was a vasomotor flush on the affected side when the pain was severe. The patient was seen a number of times in the course of the intervening seven years until May 2, 1923, when she was readmitted to the University Hospital. On May 6 the superior sympathetic ganglion was excised and the perisympathetic plexus stripped from the common carotid artery from a point 2.5 cm. below the bifurcation to 2 cm. above the external carotid artery. Result—April 11, 1927, the patient wrote that she was feeling worse rather than better and that she was never without a pulling, burning, throbbing sensation in the cheek.

In commenting on these ten cases Frazier says the records speak for themselves. In only one case did the patient obtain any relief, and in this case there still remains the doubt as to whether the relief was permanent, as the patient cannot be traced.

In conclusion, the author says, "This problem is of some importance because the number of patients afflicted with conditions that have these irregular form pictures is not small and the patients themselves lead a wretched existence. That one of the patients was entirely relieved by Christian Science suggests a functional rather than an organic basis for her pain, and one may have to be content to view the condition as of psychogenic origin and discontinue any effort to modify or relieve it by physical measures."

In a later article under the title "Fourteen Years Experience With Fractional Section of the Sensory Root as the Major Operation," Dr. Frazier has again discussed this subject. This article presents, as its title would indicate, a technic for the partial section of the sensory root in order to preserve intact the normal sensation in as large a part of the face as possible and still successfully relieve the pain. As to the reason for this modified operation the author says, "One may well inquire why so much concern about conserving as much of the root as possible. To appreciate the significance of this discussion it must be understood what the patient's reaction is to the total loss of sensation in the affected region. So agonizing is the pain that the patient before operation welcomes any measure that guarantees relief. After the operation he notices not only that there is no sensation but also that the face and tongue seem swollen. Many patients accept these and other sensory defects, and continue content so long as they can live in the happy assurance that they will never have another paroxysm. To some of the others these wide-spread sensory disturbances continue to be a source of more or less annoyance. There is a smaller group who develop paresthesias after the operation. In a few instances these paresthesias are a source of great annoyance."

We have not infrequently seen this type of case, of which the following is an excellent example.

On January 16, 1925, Mr. H. was referred to us by Dr. Alfred Hoff for the treatment of tic douloureux by alcoholic injection. Patient was 60 years old, occupation railway mail clerk, married, wife living and well, three children living and well, no history of serious illness. Has had pain of a spasmodic nature in the right side of the face for nearly a year, starting ap-

parently with a bad tooth. This was extracted. Then the pain moved to the tooth in front of this, which was likewise extracted. The pain kept moving forward until four teeth in a row in the right lower jaw had been removed. The pain still continued. Touching the right lower lip, the second right lower incisor, eating, spitting, talking, etc., brought on the pain. Pain has been so severe the past week that the patient was scarcely able to eat or talk. The response of this patient to the injection of both the second and third branches, which were successfully injected, was chiefly a change in the nature of symptoms. The severe shooting pain was stopped but in its place the patient complained of a burning, crawling feeling, especially in the right eye, which made him very uncomfortable, but he had no tic pains. You will note the burning, crawling sensations in this instance were located in the right eye, the area of the first branch and entirely outside of the distribution of the two branches which were injected. Further injections made over a period of several months did not seem to lessen the patient's discomfort. Because of this he was advised to go to the Mayo Clinic in Rochester for the radical operation, which he did. The operation seemed to increase rather than diminish the distressing paresthesias. The patient was in the habit of visiting us in the office and calling us on the phone to curse the unlucky day on which he submitted himself to the surgical procedure. The way he expressed it was, "The sensations were bad enough after the alcohol injections but many times aggravated after his operation."

We have devoted so much space to the description of such patients because in our opinion they do not indicate so much a mistaken diagnosis as they do the degree of the constitutional nervous predisposition and its sensitiveness to central reactions in such patients. We have in music Yankee Doodle with variations, and sometimes it is difficult to recognize the well known air because of the variations. So also we have migraine with variations, and likewise tic douloureux with variations, the variations depending upon the degree of burdening of both the vegetative and the cerebro-spinal nervous systems of the patients.

We have a letter from this type of patient, whom we unsuccessfully injected without relieving his severe spasmodic pain, and then afterwards gave him the treatment which we are going to describe later on. We want to read this letter. The date of this letter is March 3, and it is in answer to an inquiry of ours as to the patient's condition.

"It is now six months since you operated in my face, and it is still stiff. There is yet spotts that I don't feel a pin point. I can't open more than three-fourths of an inch. That side have been ever since I was with you. It bothers my hearing and thet ear and I have sting in that eye now and then, specially when I reed. My mouth feels inside as if it was scalld after the pain is over. I never feel anything hot ther inside. When I drink hot coffee it feels like a cold piece of rubber inside, but when I stick my finger in to feel if it is cold I find it just as warm as the other side, but when I drink cold water or milk it feels just like it run a cold stream of water outside. I hundred of times try to wipe it up and was nothing, just dry. I cannot go any place. I am afred I get cold in my chin. I was out once this winter and got cold in it. I was just to the mail box and got so stiff in my jaw so I could not open it in three days. I had to suck milk for food. Yes, there is lots of more things I could tell you. Now, Dr., I am not kiking about anything. I just will tell you how it is working on me. I must say I have had a good winter's sleep every night without thas killing like paen. but Dr. you never told me how it was going to feel in any way or acksion. I was afred ones to get lockjaw or be perliced in my face. it would not have been more than right to post me a little about what was to bee. I sokt bread in coffee and ate in the hospital for two days. I could only drink my coffee but still pey for meals. Well Dr. I will hope for the besst. Must stop, etc."

This letter has all the characteristics of the fundamentally functional nervous patient. It shows plainly that the patient is of a marked introvert type. Every sensation, and especially those affecting his face, he describes in analytic detail. Fear and worry fill his mind constantly, fear of lockjaw, paralysis, cold, apprehension of what the various sensations indicate, just like any neurasthenic. Then there is a touch of the paranoid taint shown in his reproach, "But Doctor, you never told me how it was going to feel in any way or acksion." Also in his expression relating to his stay in the hospital, "I could only drink my coffee but still pay for my meals."

It does not seem to us in the consideration of the etiology of the so-called trigger zone, which is so constant and so important in these cases since it is the spot of spots from which the pain is released, has been given sufficient importance. This trigger zone is the only place in the whole sensory area of the fifth nerve which shows any objective symptoms. Outside of this zone sensory symptoms to objective methods of examination seem perfectly normal. In this zone sensation to touch and pin prick is intensely hyperesthetic. The slightest touch or movement here, even in some cases the threat to touch, releases the spasm of severe pain. One of the peculiar characteristics of this trigger zone is that it may lie in the area which is supplied by the third

branch, as in the tongue or lower lip, while all the pain occurs in the first and second branches around the nose, upper cheek, eye, and forehead.

The successful injection of the two branches where all the pain is experienced does not relieve the pain in the slightest. In order to stop the neuralgia, the trigger zone and the branch supplying this area must be sought out and this branch injected. Another thing worth noting is that the location of the trigger zone may change quite suddenly. Whereas it may have been located the day or the week before, or in the previous attack, in the lower lip supplied by the third branch, it may leave this area and take up its abode somewhere on the side of the tongue; or even abandon the area of the third branch entirely and manifest itself in some spot in the distribution of the first or second branches.

Then again these hypersensitive spots or trigger zones may likewise disappear completely as suddenly as they came, and with their disappearance, presto, like magic the spasmodic pain stops. It is quite plain according to this that it is not the blocking of the nerve with alcohol which is the essential objective in the injection, but the rendering anesthetic the trigger zone or zones which seem to be the sine qua non in the production of the pain. The curious behavior of these trigger zones would of itself suggest the functional nature of the condition and indicate its systemic or central character.

Genuine tic douloureux may not only change its location on the same side of the face but in one attack may present itself on the right side of the face and then later on transfer its field of action completely to the left side of the face, or vice versa, the right side remaining perfectly free from either pain or any disturbance of sensation. We have also seen this phenomenon occur not infrequently in cases of migraine. The pain here may appear for years in the migrainous attack above, say, the right eye, and then without rhyme or reason leave and appear in a similar location above the left eye.

The following case of "tic" is an example of this.

Mrs. C., aged 56, occupation housewife, was referred to us by Dr. George Sherwood, January 7, 1912. At that time the patient complained of pain in the left side of her face in the distribution of the second branch in the region of the upper lip and nose. Successful injection of this branch did not relieve the pain. With the injection of the third branch, the patient obtained complete relief. A year later this patient returned with the tic on the opposite side of her face, the left side having given her no furthr trouble. An injection of the right third branch gave the patient complete relief. This patient has returned at intervals of a year or two for relief of her tic pain, which has sometimes returned on both sides of her face but for the most part the return has occurred on the left side. The last time we injected her was in June, 1927. Then, both the second and third branches on the left were injected, the right being entirely pain-free.

Our experience with tic douloureux has been largely coincident with what may be called the focal infection period and its importance in disease. We, in keeping with medical thought in general, have naturally been greatly instructed and influenced by it, especially since we were confronted with a condition which was situated so close as the face to the great centers of focal infection. The profession, particularly those surgically inclined, in times past have seemed determined to find the etiology of tic in some source of focal infection. We are of the opinion that the number of good teeth alone which have been extracted with the thought in mind that they were the chief etiological factor would run into the millions.

But some one may say that he knows of a case which was completely relieved of his pain after the removal of a bad tooth. Granted this to be true, this does not prove that the tooth was the factor. For every tooth which has been pulled with subsequent relief of pain, ten thousand have been extracted with no benefit whatever.

We have often heard of cases of epilepsy in which the epileptic attack has remained away for months after a circumcision. We would suggest another explanation for this, which is that in both instances a hyperesthetic or trigger zone somewhere has been temporarily dulled by the effect of the local or general anesthetic.

It is interesting to note what the neurological opinion on this subject was just preceding the focal infection era. Space will only permit us to quote one authority. We have selected the one who was considered the most preëminent in our language during our medical school days. This was the great English neurologist, Gowers. We will quote from Gowers' textbook on "Diseases of the Nervous System" published in 1893. Gowers says, "Neuralgia of the fifth is probably more frequent than all the other varieties to-

gether, and it presents in most typical form the characteristic symptoms of the disease. Nor is this surprising when we consider that the fifth is incomparably the most important nerve of common sensibility in the body." Of tic douloureux he says, "The pain is invariably in the region of the fifth nerve, sometimes in the whole nerve, sometimes in a part only, but rarely confined to a single branch. Convulsive spasm in the face may accompany the pain (convulsive epileptiform neuralgia)." We have quoted this last sentence especially for the name which he applies to it, "convulsive epileptiform neuralgia." Gowers also state, "Neuralgic pains are common in hysteria. Every variety of true neuralgia may be met with due to the neuropathic disposition, and they present the characteristic distribution, tender points, etc., of the ordinary forms." He speaks of hysterical neuralgia due to the neurasthenic disposition and then sharply distinguishes other forms with a different etiology as gouty, diabetic, herpetic, malarial, syphilitic, degenerative, etc. About the only difference between Gowers' article on neuralgia and more recent articles is that he makes the neuropathic type of a central and endogenous origin with the fundamental cause as the neuropathic disposition a very important etiological factor while more recent articles, influenced no doubt by the brilliant results in many diseased conditions by the removal of focal infections, tend to minimize the endogenous factor and to place more stress on some exogenous cause. In the light of our experience we would regard Gowers' article in 1893 as the more comprehensive.

We have long felt from an intimate experience with these patients in the course of twenty years of injection treatment that tic douloureux was not only, as Patrick has said, a disease "sui generis," "etwas für sich," but that the most important and essential nature of it was in the neuropathic predisposition of the patient. This conception answers another question which came up in the discussion at the time we read a paper on this subject before the State Society at St. Cloud in October, 1924. Dr. Michaels, we believe it was, asked why, if trigeminal neuralgia was essentially of a functional character, it makes its first appearance in the majority of cases in the later decades of life, while our experience with functional conditions would indicate that they appear during the early decades. The answer to this is that functional nervous conditions have appeared in these patients many years before their tic douloureux, only they presented such an entirely different clinical syndrome with varying localizations that they were never really associated either in the minds of the patients or the physicians whom they consulted as in any way having a relationship with their tic pain. We have observed many patients who substantiate in their histories this statement.

We have much evidence in our own experience as well as excellent medical corroboration to cause us to believe that a true tic douloureux presupposes the neuropathic disposition and is therefore anaphylactic, or, perhaps better, allergic in nature. By the term allergic we mean that some localization in the body is especially conditioned or sensitized because of the neuropathic predisposition through a dysfunction of the vegetative nervous system. This conditioned, sensitized localization does not necessarily need to be in the area of the fifth nerve causing tic douloureux. It may lie in the cervix uteri producing severe menstrual pain, or in a thalmic or subophthalmic area of the brain upon whose function our emotional control depends and thus produce a mania or a melancholia, or in some cortical brain area causing idiopathic epilepsy. In the case of tic douloureux the area of the fifth nerve happens to be the conditioned place.

The following case is a good illustration of what we have just been saying.

Mr. M., aged 45, a farmer, was referred to us on April 14, 1930, by Dr. Max Kern of St. Cloud, Minnesota. His chief complaint was that of a facial spasm on the left side which began four years previous and had persisted intermittently ever since. There was nothing significant in his physical or neurological examination. The significant facts were discovered in his family history. His father was an asthmatic. His mother and one brother had severe sick headaches and another brother was subject to hay fever. Here was undoubtedly a family with a marked allergic tendency in which three members at least manifested their allergic hypersensitivity by exhibiting three different clinical pictures occurring in different localizations. It must be quite evident that local irritations and focal infections in such cases could only be of minor importance. This family history should convince us of the constitutional and inherited nature of the different clinical syndromes in functional nervous conditions.

Believing firmly in this conception of all so-called functional nervous conditions and also

having the feeling that genuine tic douloureux belongs in this category, we selected a form of therapy which has in recent years, according to numerous favorable clinical reports, attained some signal successes in many functional nervous cases. This is the so-called fever therapy. This is not the place here to enter into any general discussion of the fever therapy.

Grete Drecker in an article on Fever Therapy in Schizophrenia says, "It produces an effect on the morbid process itself." Speaking especially with reference to the malaria treatment in general paralysis he says, "Through the infection the circulatory conditions in the entire body are changed and the circulation itself quickened. As a result there takes place a stimulative and tonic influence on all the vital systemic processes. In this way the defense mechanisms of the body are called forth as they are in the natural infections."

There has been much debate as to the rôle which the fever plays in the beneficial effect. What particular part the fever itself plays we do not know. We do know this, however: without a somewhat severe reaction with chill followed by a fever of at least 102° F., better 103, 104, or 105, the therapeutic effect is not so favorable.

We selected in this series of cases milk as the fever producing agent. The milk was boiled and allowed to cool and then injected intramuscularly into the buttocks four days in succession, beginning with 5 c.c. the first day and increasing the dosage on the succeeding days by 5 c.c. or a lesser amount according to the degree of reaction obtained in those cases where milk failed to react vigorously enough we used triple typhoid as the foreign protein.

We gave the milk four days in succession in order to secure a series of quick reactions. The first injection almost invariably increased the pain. Even during the height of the reaction in the fourth injection, rather severe tic pain was present in some of the cases.

In no case was the fever reaction less than 102, and in some cases it reached a height of 104 and even 105. These reactions lasted only a few hours and then quickly subsided. During the treatment and continuing for some time afterwards, we gave a capsule containing from one-half to two-thirds of a grain of phenobarbital with 10 grains of calcium lactate after each meal. In some of the cases during the reaction morphine or some derivative of it was administered either hypodermically or by the mouth, as needed to make the patients comfortable.

We have treated ten cases thus far according to this method. In all of these patients the tic was of long standing. One case was first injected with alcohol by us in 1908. During all this time this patient, whenever her pain came back, which it did at intervals varying from one to several years, returned for another injection. So it may be said of these patients that they knew their tic. They also had very little faith in any other form of therapy other than the alcohol injection. It was not easy to persuade them to accept any other plan of treatment.

The first patient was Mr. S., 80 years of age, salesman, referred to us in 1927 by Dr. T. J. Moynihan of this city. His first alcohol injection was May 19, 1927. His last was two years later on May 25, 1929. On August 16, 1929, this patient came to the office complaining of severe tic which kept him awake during the night and made it very difficult for him to eat or talk. He was given 5 c.c. of milk intramuscularly; also the capsule mentioned before. The patient was directed to return to his home in Minneapolis and go to bed at once. In our experience it is usually an hour or longer after the injection before the reaction occurs. The next day he was unable to come to the office but reported having had a severe chill after going to bed, followed by fever, increased tic pain in his face and a general malaise. When we saw him several days later he had not entirely recovered his strength. As he was free from pain we did not repeat the milk injection but continued his capsules. Since this time we have had two reports from this patient. On November 15, 1929, he wrote us that for two weeks after his operation he was entirely free from pain. After that he was for several nights awakened by severe pain once each night, and during the daytime said that touching either the left side of his nose or the upper lip caused flashes of pain in the face, not of a severe nature. "These little pains," quoting from patient's letter, "kept up right along until three weeks ago when they suddenly ceased troubling me and I have been entirely free from pains of any sort in the nerve ever since." On March 21, 1930, the patient came to office to report on his condition. He said he had had only two attacks of real sharp pain since his report to us in November. These were about two weeks apart, and the last one was three weeks previous. They lasted only a few seconds. There is hardly a day, however, when pressure on his lip will not give him a little sharp twinge, and sometimes he notices it in eating. He still takes his capsule regularly.

The result in this patient cannot be said to have been entirely satisfactory, but he has been much more comfortable than he was before. We

must also remember that he only had one milk injection. His pain has never been troublesome enough since to cause him to feel the need of another injection.

Space will not permit us to report all of these cases. We will report only the ones which were especially difficult, where the trigger zones were not only numerous but also hard to penetrate with alcohol.

The first case of this character was Mr. E., aged 46, referred to us by Dr. Carl Larsen on September 28, 1926. This patient had very severe attacks of tic pain in the second and third branches of the fifth nerve on the left side of the face. His chief trigger zone seemed to be located around the base of the tongue and the pillars of the fauces on the same side, a hard place to reach with the alcohol. He was injected by us successfully at that time and once afterwards in November of the same year. He then remained free from pain until September, 1929. At this time his pain returned in the same locality and to the same agonizing degree. This patient was also a bleeder, which made the alcohol injection still more difficult. We injected the third branch first, successfully, but without relief of pain. In attempting to inject the second branch a severe hemorrhage occurred which caused such a swelling of the entire face that a repetition of the injection before the subsidence of some of the swelling was impossible. Here a difficult situation presented itself. The alcohol injection together with the swelling, only seemed to aggravate the patient's painful attacks. In order to relieve the patient in this dilemma we suggested the milk injection to him. We gave him the first injection and a prescription for the capsules as in the first case and permitted him to return home. Although the patient was a very robust individual all of his reactions were exceedingly severe. The patient's wife telephoned me the morning after the third injection saying that her husband had been restless, feverish, and a times delirious, during the night, and wished us to come and visit him. We found him with a temperature of 103, pulse 100, in a somewhat drowsy and stupid condition. After a good saline catharsis, by the evening of the same day all of these symptoms had disappeared. After the second injection of milk the patient never had another tic pain. A letter from him on the 14th of last month says, "In answer to your letter in regard to the trifacial neuralgia treatments you gave me six months ago, they sure helped me as I have had no pain at all since. Feel fine. Thanking you kindly, etc."

The next patient was Mrs. J., aged 66, referred by Dr. Victor Thompson of Marine, Minn. She was a housewife, lived in Stillwater, Minn., and the working diagnosis was tic douloureux of the right side. The patient had had pain in the right side of the face since November, 1925. The patient consulted us the first time April 5, 1926, because her pain had become unbearable. At this time both the second and third branches of the right fifth nerve were injected. These injections gave her complete relief from pain until in August, 1928, a period of over two years. On August 27, 1928, the right third branch was injected because her pain had returned. The patient was again relieved of the pain until in October, 1929. On October 26, 1929, we again injected the right third branch, securing anesthesia in its whole area except for a small spot on the right side of the tongue at its very tip. This region still remained sensitive to pin prick and the patient's pain continued the same as before the injection. Having in mind our success with the patient just reported we changed our treatment from the alcohol injection to the milk. On October 26, 1929, the patient was given 8 c.c. of milk intramuscularly and on the three following days 10 c.c. The reaction after each injection was quite marked, accompanied by chill and fever. After the second milk injection the pain disappeared completely. A letter dated March 5, 1930, from the patient says she had not had any pain since the last treatment.

The next patient, Mrs. R., was 42 years of age in 1908 when we first injected her. She has been successfully injected at different periods since then, the last time on February 4, 1929. On November 9, 1929, this patient returned for another alcohol injection. Instead of the alcohol injection she was given the four milk injections with fair reactions. Some pain, however, still continued after the fourth milk injection, so my associate, Dr. Engberg, after an unsuccessful alcohol injection repeated the four milk injections on November 19, 1929, just seven days after the first series. During the last injection the patient had a moderately severe anaphylactic reaction which was promptly relieved by a hypodermic of adrenalin. The patient after this series was relieved of her pain. A letter received from this patient dated March 4 said she had some "jumps" from jaw to tongue but no pain. By "jumps," from our previous experience with this patient, she means some muscular twitching in this locality.

The last patient which we will report at this time is Mrs. K., aged 54, referred to us September 16, 1925, by Dr. James Blake of Hopkins, Minn. In the history at that time, the patient stated that she had always been well except for severe migraine in her earlier years, especially at her menstrual time and when she became excited. This patient had trigger zones in all three branches of the right fifth nerve, so all three branches were injected. It was somewhat difficult to stop her pain but this was finally accomplished.

She remained pain-free until last summer, when the pain gradually returned and in September became quite severe. On October 2, the patient came to the hospital and all three branches of the right fifth were reinjected in the course of four or five days. Although the anesthesia produced by the injections seemed good, especially in the second and third branches, the pain still continued, apparently starting from various places in the distribution of the first branch. On October 17, 18, 19, and 20 the patient was given injections of milk: 5 c.c. the first day, 10 c.c., 12 c.c., and 15 c.c. on the the succeeding days, reacting well to each injection. The pain stopped in this patient between the second and third injections. In a telephone conversation last

week with her physician, Dr. Blake, in regard to her present condition, Dr. Blake said the patient was in good health and pain-free.

We have either letters or reports in person from all of the ten patients who have received the milk treatment, and thus far they have all remained pain-free except the first patient reported, who received only one milk injection. Before discharging these patients, we subjected them to all the irritations which had formerly started their pain, asking them to try in every way to bring on their pain by eating, drinking, talking, etc., and then, when they were unable to do so, by rubbing both lightly and vigorously the places where the trigger zones had previously existed.

Whether this method of treatment is going to be an addition to our therapy of tic douloureux, neither the number of cases nor the length of time which has elapsed since they have been treated will of course permit us to say. We do not in our fondest imagination expect it to supplant either the need for the injection of alcohol or the radical operation, as time and voluminous clinical experience from many sources have established the undoubted value of both these procedures. We simply report this treatment as our experience in ten cases. We know in these cases it has helped us greatly to deal successfully with some very difficult situations.

RULES OF THE COMMITTEE ON FOODS

The Committee on Foods of the Council on Pharmacy and Chemistry publishes a revised statement of the information which should be submitted to the Committee by manufacturers who wish their food products included in the book "Accepted Foods." The Committee will consider all food products for which health claims are made as coming within its purview. If the health claims made are satisfactory to the Committee, in view of the composition and process of manufacture, the Committee will accept the product for its book "Accepted Foods," and will grant to the product the use of the seal of the Committee. If the product is found to be outside the scope of the Committee in that no health claims are made for it, and if the product and the advertising are otherwise satisfactory, the product will be exempted. A list of exempted products will be published in the book "Accepted Foods," and such products will be permitted to be advertised in the publications of the American Medical Association. A list of rejected foods will be published in the book "Accepted Foods" together with the reasons for such rejections. Rejected products will not be permitted to advertise in any publication of the American Medical Association. Infant foods, whether health claims are made for them or not, are considered to be within the scope of the Committee's consideration. (Jour. A. M. A., May 3, 1930, p. 1407.)

COLLOSOL KAOLIN NOT ACCEPTABLE FOR N. N. R.

The Council on Pharmacy and Chemistry reports that Collosol Kaolin is the name given by the Crookes Laboratories, Inc., to a product stated to be "a prepared clay, giving a comminuted chemically inert material of high absorptive capacity." The use of the product is recommended in various conditions, including rheumatism, neuritis and asthma. The Council points out that the Germans, who had employed it against dysentery during the war, abandoned its use and substituted charcoal. The Council declared Collosol Kaolin unacceptable for New and Non-official Remedies because of the unwarranted therapeutic claims and because of possible dangers from the therapeutic use of the product. (Jour. A. M. A., May 3, 1930, p. 1406.)

RECRESAL NOT ACCEPTABLE FOR N. N. R.

The Council on Pharmacy and Chemistry reports that Recresal is the product of Chemische Werke vorm. H. & E. Albert, Wiesbaden-Biebrich, Germany, and that, according to the information received from this firm, the product is sodium phosphate monobasic and is therefore nothing more than the well known acid sodium phosphate, which is official in the U. S. Pharmacopeia as sodium biphosphate. (Jour. A. M. A., May 3, 1930, p. 1406.)

MODERN TREATMENT OF VARICOSE VEINS*

James M. Hayes, B.S., M.D., M.S., F.A.C.S.
Instructor in Surgery, University of Minnesota,
Minneapolis

MUCH has been written recently concerning the modern treatment of varicose veins—sufficient, perhaps, to convince the medical profession that surgical removal of varicose veins is almost a procedure of the past. Having made over 10,000 injections on over 1,000 patients during the past eight and one-half years, we are convinced of the efficacy of this treatment.

HISTORY

Since the invention of the hypodermic syringe, attempts have been made to obliterate these veins by the injection of various solutions, but not until 1911 did this become an approved and practical method.

Linser observed that in postoperative and postpartum phlebitis, the thrombosed vein usually became fibrosed and gradually disappeared by absorption. He also observed that in the treatment of syphilis with bichloride of mercury the injected vein frequently became thrombosed, fibrosed, and gradually absorbed. These two observations led him to attempt the obliteration of varicose veins by means of bichloride of mercury injections. From 1911 until 1916 he used this exclusively as a sclerosing solution. He and his followers made many thousands of injections with practically no serious results. His end-results far surpassed any method which had been employed for the treatment of varicose veins up to that time.

In 1917 he substituted a strong sodium chloride solution for the bichloride of mercury solution. He believed this was an advanced step for two reasons: (1) because of the more rapid results obtained, and (2) because of the "entirely unfounded aversion" of many medical men to intravenous injection of bichloride of mercury. The latter prevented the widespread use of this method. Many of our most ardent advocates of this method in this country have acquired this "entirely unfounded aversion" to the injection of bichloride of mercury.

In 1925 Linser first published his results with sodium chloride as a sclerosing solution. About 1916 Sicard of Paris began the same work, using sodium bicarbonate; later he substituted sodium salicylate, which is still used widely for this purpose in France. In 1923 Genevrier published his results using quinine hydrochloride and urethane. This solution still holds an important place among sclerosing solutions. In 1926 Nobl of Vienna published his results with calerose, an invert sugar, as a sclerosing solution.

This work was first introduced into this country by Kretchmeier, who came to this country from Germany about 1920. He did his first work at the clinic at Red Wing, Minnesota. He left no written record of his work but some of his patients presented themselves at the Out-patient Department of the University of Minnesota for a continuation of this treatment. His results convinced us that the work was far in advance of anything we had been doing for these unfortunate patients and deserved investigation.

After reviewing the German and French literature we began this work in December 1922. The two solutions widely used at that time, according to the records in the literature, were bichloride of mercury in Germany and sodium salicylate in France. The medical profession of this country were naturally very skeptical then and almost universally advised the patients against it. We, therefore, selected only the most refractory cases. During the first year we selected only those patients with badly ulcerated conditions (Figs. 1 and 2). Those ordinarily considered surgical were refused treatment.

We tried the two solutions about which we had authentic reports of good results—sodium salicylate and bichloride of mercury. Sodium salicylate when injected into the vein caused a severe cramp. Already advised against this method of treatment by physicians, this cramp was frequently sufficient to frighten the patient away and the treatment was at an end. Bichloride of mercury when injected into the vein usually gave no unpleasant sensation at the time of injection. The patient submitted to this more readily and returned for repeated injections. This led us to

*Read before the meeting of the American College of Physicians, Minneapolis, Feb. 12, 1930.

the almost exclusive use of this solution until 1925, when Linser published his results with sodium chloride solution.

SCLEROSING SOLUTIONS NOW IN USE

Bichloride of Mercury (1 per cent solution). This solution is placed first not because it is the solution of choice for this work but because it was the first solution to fulfil effectively the requirements of a sclerosing solution. We used it almost exclusively from 1922 to 1925. Until Linser published his results with sodium chloride solution, we found no solution more desirable.

We have made in all over 5,000 intravenous injections of bichloride of mercury, and in no case in which we limited the amount to 1 c.c. of a 1 per cent solution at one session did we get any untoward results except an occasional slough.

We have had, in all, four cases of enteritis. In two cases we injected more than 2 c.c. at one session. In one case we injected sodium chloride in one leg and bichloride of mercury in the other leg. This patient had an enteritis for nearly two days, but then cleared up promptly. In one case we injected invertose in one leg and bichloride of mercury in the other leg. In this case we produced vomiting and a bloody diarrhea which lasted for nearly two days. The patient went to work on the third day.

We still use this solution in selected cases. In very sensitive patients we frequently start the patient with this solution. When it is necessary to inject hard, fibrotic, or infected areas, this solution is often the solution of choice. Occasionally we find a case in which we are unable to obtain obliteration with other solutions and do get results with this solution. We rarely inject this solution more often than every second day, although it has been shown that practically all bichloride is eliminated in twenty-four hours. The results with this solution are necessarily slow and we usually use salt or sugar solution for large or extensive varicosities.

Sodium Chloride (20 per cent solution). Sodium chloride solution gives excellent and rapid results; perhaps more rapid than any other solution now in use for this purpose. The two important objections to this solution are, first, the disagreeable cramp accompanying the injection and, second, the extensive slough produced by a perivenous injection or even by a slight seepage of the solution into the perivenous tissue.

Sodium Salicylate (20 per cent solution). This solution gives a fairly consistent thrombosis. The cramp accompanying the injection and the slough caused by escape into perivenous tissue are much

Fig. 1. *(Left)* Type of cases treated during our first year in this work.
Fig. 2. *(Right)* Ulcer open for nine years, now closed for eight years. Operated three times previously.

the same as those produced with sodium chloride solution. It cannot be used in large doses, Occasionally it may produce a thrombosis when other solutions fail.

Quinine Hydrochloride and Urethane (10 per cent solution). This solution produces less slough than the above mentioned solutions if it escapes into the perivenous tissue but cannot be used in large doses without producing unfavorable symptoms. It should not be used in pregnant women.

Invert Sugar (50 to 75 per cent solution). Invert sugar, perhaps, more nearly than any solution so far reported, fulfils the role of a sclerosing solution. It seldom produces cramp. It very rarely causes a slough in the perivenous tissues. However, it does not give as consistent results as any of the afore-mentioned solutions. The density of the solution necessitates a larger needle. This increases the discomfort to the patient and makes entrance to the vein more difficult.

The almost entire absence of slough and cramp makes this the solution of choice in the great majority of cases. We much prefer the stronger solution. The weaker fails to thrombose in many cases. If we do not get results with this solu-

tion we then try others. Nobl says he does not expect greater than 90 per cent of results with invert sugar.

Mixture of Dextrose (50 per cent solution) and Sodium Chloride (30 per cent solution). Recently this mixture has been put on the market.

Fig. 3. Shows destruction of intima at site of beginning thrombus.

The results are excellent so long as none escapes into the perivenous tissue, but otherwise a troublesome slough results. Dextrose (50 per cent solution) gives very good results but not so consistent as when mixed with salt.

As we travel from clinic to clinic in this country as well as in Europe it is interesting to observe the enthusiasm of various men over some favorite solution or particular method of treatment. No doubt one does become more proficient with any particular solution or method he has employed for a long period of time, but any of the above mentioned solutions will give excellent results with faultless technic. Merely getting the solution into the vein and keeping it there will give a high percentage of thromboses, but a more refined technic will give a more consistent thrombosis.

APPARATUS AND AMOUNT OF INJECTION

We use a 2 c.c. Luer syringe for bichloride of mercury, quinine hydrochloride and urethane, and sodium salicylate solutions with a gauge No. 26 needle. We never use more than 1 c.c. of a 1 per cent bichloride of mercury, 2 c.c. of quinine hydrochloride and urethane, or 5 c.c. of sodium salicylate solution, at one session. With sugar and salt solution we use a 5 c.c. or 10 c.c. syringe, making two or three injections of 5 c.c. or 10 c.c. at one session. For invert sugar we use a gauge No. 21 needle.

CONTRAINDICATIONS

The more we have observed the results of this work the more we feel that the contraindications are very limited. Practically every patient who is not disabled by some other pathological condition may have his varicose veins treated by this method if cautiously done. Diabetics are treated if they are sugar free at the time of treatment. Nephritics are treated if their symptoms are not marked. These patients must be treated cautiously.

We have recently treated over forty cases of old thrombo-phlebitis with good results. We usually do not accept them for treatment if they have had an acute thrombophlebitis within a period of six months or unless we are certain of the lack of function of the involved vein. In these cases we always go slowly and cautiously. If the thrombosis is not extensive it is not likely to cause trouble in any of these conditions.

Pregnant women are treated to relieve distressing symptoms. If it is the first pregnancy and the patient is experiencing no marked distress, we usually advise her to wait until after childbirth. The varicose veins will frequently then disappear. If they persist between pregnancies we do not hesitate to produce a rather extensive thrombosis, if necessary, during pregnancy.

EMBOLI

During the first years of this work we were continually asked if we were fearful of emboli with this treatment. The records of the German and French work had convinced us that it was not so important a factor as one might suppose.

The thromboses we had been accustomed to observe had been, perhaps, in most instances, infectious in origin. These are produced by a chemical irritation of the intima causing a necrosis of the intima (as shown in Fig. 3) with a deposit of fibrin from the blood at this point and a consequent interweaving of the clot with the wall of the vessel. This made the breaking

off of emboli less likely than in the ordinary thromboses which usually lie loosely in the lumen of the vessel.

A study of the varicose veins has indicated the absence of circulation in these vessels. The valves become incompetent and the blood stands in them much the same as water in a stagnant pool and merely seeps through the communicating veins into the deep veins where it is carried back into the main circulation. Jentzer, with radiograms after the injection of strontium bromide into the veins, first demonstrated that the varicose vein really filled from above and emptied into the deep veins below (Fig. 4). Sicard later confirmed his work with radiograms after the injection of lipiodol. This would indicate that emboli, if they should break off, would be more likely to pass distally than in the normal direction.

However, the fact that pulmonary emboli have been demonstrated following these thromboses indicates that the above is only partially true and that under certain conditions the blood may pass in the normal direction and carry emboli to the pulmonary artery.

McPheeters and Rice, in reviewing the literature, collected 53,000 cases injected for treatment of varicose veins, with only seven fatal pulmonary emboli. This is a small percentage of mortality, yet high enough to warn us against any procedure which might increase the possibility of this unpleasant complication. In over 10,000 injections we have observed no case in which anything of this nature has occurred. Kilbourne calls attention to the fact that fatalities from pulmonary emboli have occurred for the most part in cases that have received a large number of injections at one session, or in those with a recent thrombophlebitis.

NUMBER OF INJECTIONS AT ONE SESSION

Some of the advocates of a large number of injections at one session argue that we never thrombose more than the varicose vein. This is not entirely true. The discovery of this method of thrombosing veins resulted from thrombosis of the normal or apparently normal veins of the arm following the injections of bichloride of mercury for the treatment of syphilis. Perhaps thrombosis does not extend widely into normal veins. With a small number of injections this may be negligible, but with a large number of injections it may become quite extensive. This would necessarily increase the back pressure in the veins and consequently make pulmonary emboli more likely. We do not believe it advisable to unnecessarily increase the probability of pulmonary emboli.

Sugar solutions, which are now becoming the most popular for this purpose, must necessarily be used in the form of a rather dense liquid. This requires a comparatively large needle. We have found that the vast majority of patients much prefer to have not more than two or three injections at one time, and to return as often as required. The ultimate results are the same. Also a very extensive thrombosis may be accomplished by two or three injections (Fig. 5). Ten or twelve injections, as advocated and practiced by some men, not only would have been superfluous here but would have been an injustice to the patient.

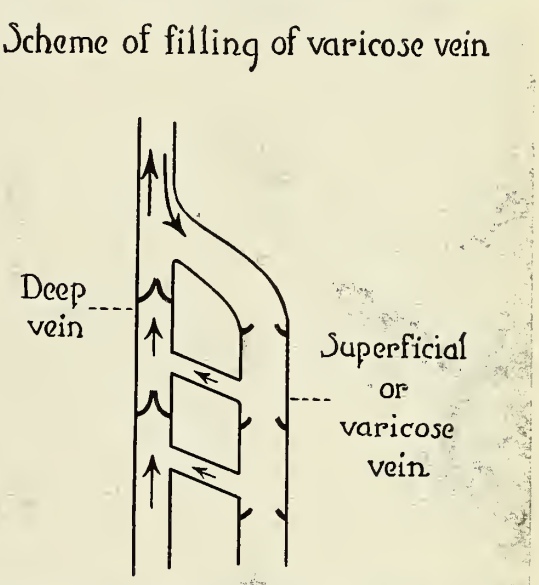

Fig. 4. Shows incompetent valves in varicose vein. Vein fills from above and blood seeps through to deep veins.

The great majority of men throughout the world who are doing this work undoubtedly agree that too many injections should not be given at one session.

TECHNIC

When we began this work in 1922 we were not satisfied with either the technic practiced in Germany or that in France. With the former, the work was difficult to carry out and apparently much time wasted. With the latter, our percentage of thromboses was not as high as we desired

it to be. According to the former, the patient was put in the prone position with the leg raised, the vein emptied by force of gravity, constrictors put on above and below the point of injection,

Fig. 5. This entire vein on right from malleolus to groin was thrombosed by two injections.

and, presumably, the empty vein entered with the hypodermic needle. In our experience, one can be sure he is in the vein only by the aspiration of blood. If the vein is collapsed or the blood all forced out of it previously, how can you aspirate blood? Practically we have found that considerable blood enters this portion of the vein through communicating branches from the deep veins, and we are not getting a collapsed or empty vein, but only increasing the difficulty of entering it.

In injecting the full vein with the patient in the erect position, as practiced in France, our solution is diluted to a degree that it does not give the desired result in a large percentage of cases unless we inject a large amount of solution, thus displacing the blood.

The object here sought is to have the injected solution come in contact with the intima of the vessel in an undiluted form, thus giving the maximum of chemical irritation at this point. The chemical irritation causes necrosis of the intima, as shown in Fig. 3, thus bringing about the desired thrombosis.

The method we have used mostly for several years, we first mentioned in 1924. We have tried every other method that we have observed or have seen described in literature, but have found none so simple or more effective.

We have the patient sit up or stand on the table, usually in the position in which the most marked distention of the vein occurs. We insert the needle into the distended vein, then with the palm of the left hand gently compress the vein over the site of the injection (Fig. 6). Here we are careful to have the pressure extend back of the entering point of the needle so as not to force the fluid back into the perivenous tissue. We are careful not to release the pressure in binding on the pad, as shown in Figure 7. This pad we usually leave on until the following morning and the patient then removes it. For several years we insisted on the patients buying elastic bandages to wear over the entire lower leg during this treatment. We have abandoned this entirely unless the patient chooses to wear one for comfort.

We have tried the various methods on successive days and after one month attempted to distinguish between the results. After some time we concluded there was no method that gave better end-results than this method just described. The method is simple and requires a minimum of apparatus and lost motion.

COMPLICATIONS

The only complications we have observed were perivenitis and slough.

Perivenitis. — Perivenitis, so-called by the French, frequently worries the patient and at first worried us, and especially worried the medical man who by chance saw one of these patients before he was acquainted with this method of treatment. The area for some distance from the point of injection frequently becomes swollen, red, hard, feverish, and quite painful. Fortunately, we can usually truthfully tell the patient that the more marked these symptoms are, the more extensive are the results.

We usually advise hot applications and possibly some mild drug for the pain. Usually this does not give them trouble more than two or three days.

Sloughs.—Sloughs, we must admit, are due to faulty technic, but most of us who have followed this work for any great length of time have had them occur.

With the various sugar solutions, we have had practically no sloughs. With quinine hydrochloride and urethane, sloughs have been almost negligible. Sodium chloride, sodium salicylate and a mixture of dextrose and salt solution have given us our most extensive sloughs. Bichloride of mercury solution always gives a slough when injected perivenously but the slough is usually not so large as that produced by the other solutions just mentioned. If the solution escapes into the perivenous tissues at the time, the patient usually complains immediately of a local burning sensation. If we are in doubt we usually inject a large amount of novocain solution before sterile water. This usually dilutes the solution to such a degree that the slough is prevented. The inevitable slough usually shows up on the day following the injection. There is usually a dark bleb with a dark area underneath.

Treatment of Sloughs.—Usually the slough does not cause very severe pain unless infected. If infected, an Ochsner's pack will clear this up in two days. After four or five days the slough may be cut out to some extent without much pain, keeping within the area of necrotic tissue. We usually pack the cavity with gauze soaked with 1 per cent Dichloramin T. We are always careful to cover the skin with vaseline gauze to prevent irritation. The Dichloramin T usually dissolves away the necrotic tissue. After the necrotic tissue is dissolved away we dust on a little calomel powder and pull the edges of the ulcer together with adhesive.

These sloughs are slow to heal and a source of considerable annoyance to the patient. We hope some time to be able to avoid them.

Ulcers.—Our first work over eight years ago dealt only with patients who had already had ulcerations (Figs. 1 and 2). We then used the Unna cast (Fig. 8) in all cases until the ulcer was healed. We now use it only in the very extensive ulcerations. If the ulcer is not too large we use the sponge pressure method. This gives us more rapid healing than we have observed with any other method.

If there is acute infection in or about the ulcers we put on the Ochsner pack for forty-eight

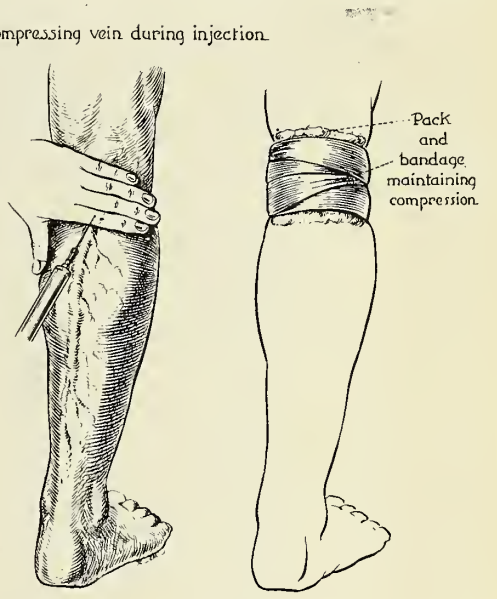

Fig. 6. *(Left)* Shows method of compressing vein to force out the blood during injection.
Fig. 7. *(Right)* Pad bound on to maintain compression following injection.

hours. We then clear away any loose or sloughing tissue. If the granulation tissue protrudes above the epithelium at any point we touch this with a stick of silver nitrate. Silver nitrate should not be used otherwise. We then dust on a very light layer of calomel powder, cover the area with vaseline gauze, and bind the rubber sponge on very firmly. The elasticity of the sponge prevents shutting off of the blood supply below. The pressure forces out the fluid from the edematous area about the ulcer and produces a fairly normal appearing tissue.

We begin injecting the veins as soon as the patient is seen and continue until the varicose veins are all thrombosed. This hastens the healing of the ulcer.

THE TRENDELENBURG TEST

The Trendelenburg test for function of the deep veins is rather confusing as ordinarily described. We were much more concerned about it several years ago than we are now.

The history and general appearance of the leg will usually give one a fairly definite idea as to the function or absence of function of the deep veins. If there is any doubt, one should pro-

ceed slowly. One or two injections will rarely cause any great harm if the deep veins are thrombosed. If there is much swelling or edema after this injection, the work may be discontinued and taken up later. If there has been a recent thrombophlebitis, no injection should be made.

Fig. 8. The Una cast cut and turned back, exposing the healing ulcer.

Fig. 9. Could not demonstrate Trendelenburg test in this patient. Injection treatment gave very good results.

SITE OF INJECTION

If there is an ulcer present, we usually aim to inject the vein in the immediate vicinity of the ulcer first. This will hasten the healing of the ulcer. In other cases we usually select the distal veins first if they are easily accessible; if not, we go higher and the distal may become prominent later. Each injection will ordinarily thrombose about three or four inches of the vein. Occasionally one injection will produce a very extensive thrombosis, possibly throughout the length of the vein (Fig. 5). We usually do not choose a site where the vein is too superficial. Frequently portions of the vein appear through the skin like a blue bleb. These points are usually not chosen for a site of injection. They are difficult to thrombose directly, perhaps because of changes already taking place in the intima. Occasionally a slough will result if the solution is injected directly into this point. If the injection is made at some distance from these points, the thrombosis may extend through them and give good results. We usually do not inject more than three or four inches above the knee except in very superficial veins. In the latter, we sometimes inject above the middle of the thigh.

FREQUENCY OF INJECTIONS

We usually arrange this about as the patient prefers. If the patient is in a hurry we may increase the number of injections at each session. The injections may be made every day, every second day, or once or twice a week, according to the resulting reactions. If the reactions are severe we usually give them a longer interval between injections. If the reactions are slight we do not hesitate to make daily injections.

RECURRENCES

It is frequently difficult to determine late whether canalization of the thrombus has taken

place or a branch previously unnoticed has become dilated. We have seen several patients, who had recently had surgical removal of varicose veins, return in a year or more with very prominent varicose veins. These evidently had not been considered at the time of the operation, but have become practically as troublesome as the original veins.

The same is true with this method, but here the patient will usually return for further treatment while in the case of surgical removal the patient seldom cares to submit to the second operation. In many instances, when the patient was relieved of all symptoms, he failed to return until he again had troublesome symptoms.

We cannot recall a single instance in which we were not able to thrombose the vein, nor have we failed to relieve the symptoms when we were certain they were due to varicose veins. In many instances we have failed to produce a thrombosis with a particular solution, and have resorted to the use of other solutions until the results were obtained. When we have thrombosed the prominent veins and relieved the patient's symptoms, we tell him to discontinue the treatment and return in from one to three months, or sooner if symptoms arise. We have had from 10 to 15 per cent of our patients return for further treatment. Some returned within six months; some returned from one to eight years later. No doubt the canalization of the thrombus had taken place in some cases, but for the most part it seemed that new varicose veins were the cause of the patient's return.

CONCLUSIONS

1. The sclerosing method of disposing of varicose veins has become the method of choice.
2. Many useful solutions have been employed for this purpose, but the ideal solution has not yet been brought out.
3. Practically every active patient, or one who is not disabled by other disease, may have his varicose veins treated by this method if very cautiously done.
4. Emboli do occur. They are rare, but every possible precaution should be taken to avoid them.
5. The most troublesome complication now is the slough. This complication may be reduced to a minimum with extreme care.
6. We have not found any one particular solution applicable in all cases. If good results are not obtained with one, another may give the desired result.
7. The erect or sitting position, entering the vein in a distended condition, and then collapsing it with gentle pressure, is the simplest method. None has proven more effective in our hands.

AN ANALYSIS OF 100 CONSECUTIVE CASES OF BACK STRAIN*

Myron O. Henry, M.D., F.A.C.S.
Minneapolis

THIS clinical study was undertaken to determine the relative frequency and importance of the various findings in cases of back strain occurring in a private practice limited to diseases and injuries of the bones and joints. The cases were taken consecutively, and analyzed carefully as to history, clinical and x-ray examinations, treatment and results.

INCIDENCE

Sex.—As might be expected, 70 per cent of the back strains occurred in males, due, of course, to their more hazardous occupations and greater muscular activity. While 30 per cent occurred in females, fourteen of these (or nearly one-half) gave no history of external violence. Postural back strains seem to be more common in women, as are strains due to work in the stooping position. In this series only 3 per cent followed parturition.

Age.—Strains of the back occur most frequently in early adult life, which is the period of greatest physical effort. The average age in this series was thirty-one and one-half years, but the range was from seventeen to sixty-six years of age.

ETIOLOGY

Back strains are nearly always considered the result of trauma of some sort, yet in this series 25 per cent gave no history of external violence of any sort! Automobile accidents caused about 25 per cent of these cases, and the strains produced in this manner were usually the more serious. Other accidents of violence, such as occur in industrial or railroad work and the vigorous sports, accounted for 20 per cent. Heavy lifting or slipping while carrying loads caused an additional 10 per cent, while falls alone produced 13 per cent. Trauma, or external violence in the ordinary sense, then, was the etiological factor in 68 per cent of these cases.

Bending or working in a stooped position was considered the cause of the trouble by 6 per cent of these patients, and 3 per cent of them dated the onset back to parturition.

SYMPTOMATOLOGY

All of these patients complained of aching, stiffness or pain in the lower back, and on this account they came for relief. The pain was usually described as diffuse over the lumbosacral region, but occasionally was more definitely limited to the right or left side. Pain radiating down the back of the hip, thigh, or leg, or around into the inguinal region was more rarely mentioned. The specific complaint of stiffness in the back was mentioned by 68 per cent of these patients. It is worth while to ascertain, if possible, what aggravated or relieved the pain. The location, character, and distribution of the pain should be determined so far as possible.

In private practice, however, the examiner must sometimes look askance at subjective complaints relating to the lower back until he learns whether or not there is compensation or litigation pending. In this series 36 per cent of the cases were either involved in compensation claims or were in some way connected with litigation. One tends to evaluate the subjective complaints differently in such cases unless the objective findings seem to agree.

OBJECTIVE FINDINGS

List, or lateral deviation of the spine as a whole, is the first sign noted on examination of the patient. Inspection must include the entire posterior surface of the nude body to be of any value. A list appeared in 23 per cent of these cases (due to a short leg in 2 per cent). The list is usually away from the side complained of, but occasionally is toward the sound side. Smith-Petersen believes that a list results from the patient's attempt to avoid transmission of weight through the affected side, and is due to muscle spasm. This was certainly true in 13 per cent of these cases, but in the additional 10 per cent presenting a list there seemed to be little or no muscle spasm

*Read before the American College of Physicians, Minneapolis, February 14, 1930.

demonstrable. We interpret some of these lists as having a mechanical derangement of one of the small postero-lateral articulations of the lumbo-sacral joints. By this is meant actual overriding of one articular facet on its fellow with locking in the dislocated position,

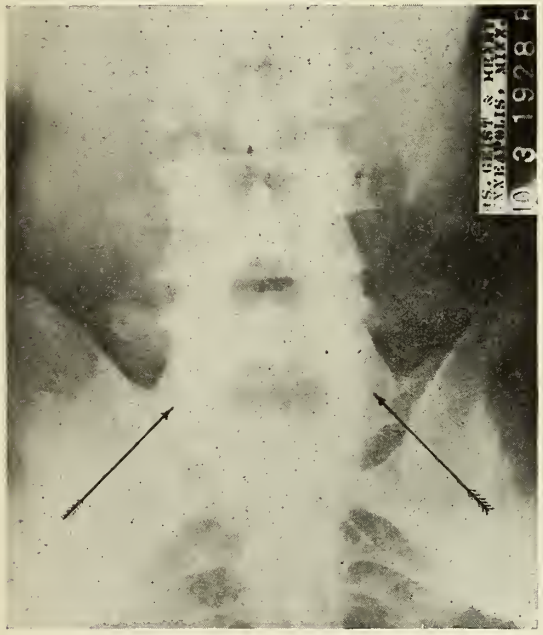

Fig. 1. Normal spine (note position of postero-lateral articulations).

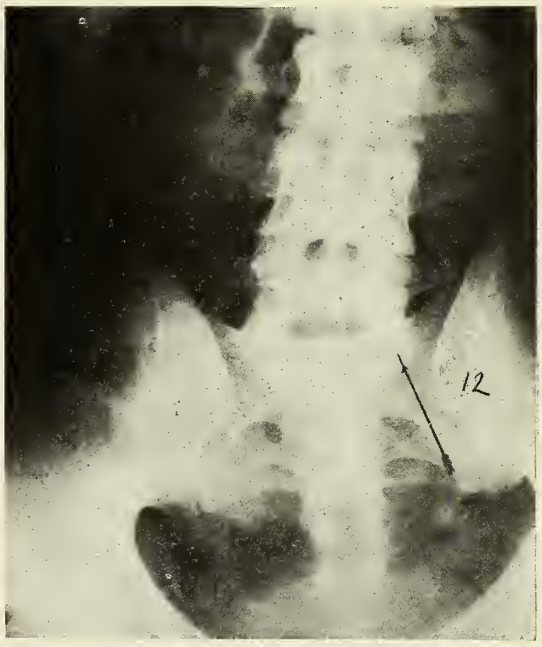

Fig. 2. Unilateral abnormal variation of articulations, with list.

or pinching of the synovia, capsule, or ligaments of the joint in the rebound of these articular surfaces when they have been displaced beyond their normal limits of motion. Such derangements are not demonstrable roentgenologically because these cases always have "abnormally placed" articular facets, that is, the small postero-lateral lumbo-sacral joints are congenitally placed facing antero-posteriorly instead of mesially as is considered "normal" in this region. In this series every patient presenting a list also had so-called "abnormal" articulations, except one patient who had a short leg.

Faulty posture was noted in 20 per cent of these cases; and by this term, we include only Class D postural ratings according to the Boston classification; that is, extreme exaggeration of the normal spinal curves, with flat chests and prominent abdomens. Under this heading, other defects in statics are included as well as deformities, but none of importance obtained in this series except two mild cases of scoliosis. It is interesting to note that postural back strains appeared in women three times as often as in men, and, when appearing in males, the individuals were always of poor muscular development.

Crepitation was definitely present in 4 per cent of the cases. This is always sought for when testing range of motion of the first time. It can usually be palpated over the lumbar region, but is sometimes rough enough to be audible as well. Of course, this finding occurs oftener in older individuals but is sometimes present in younger adults with arthritic tendencies. It is not always found in cases presenting definite spurs and lipping on x-ray, and, on the other hand, may be found in cases having "normal" roentgenograms.

Limited motion is the most important and reliable sign in cases of back strain, and was present in 47 per cent of this series. Range of motion was first checked in flexion, extension, side bending and rotation with the patient standing and not bending his knees. The range of flexion was then re-checked in the sitting position because the muscle spasm often relaxes in the sitting position in sacro-iliac cases. Limited motion is usually due to muscle spasm —reflex splinting to protect the injured parts of the back and prevent pain—but, of course, spondylitis limits motion whether appearing alone or with strain superimposed. In the lat-

ter type of limitation, the x-rays are helpful in disclosing arthritic changes, antecedent fracture, tuberculosis, spondylolisthesis, etc., which conditions per se are not included in this analysis.

Muscle spasm, as a definite objective sign,

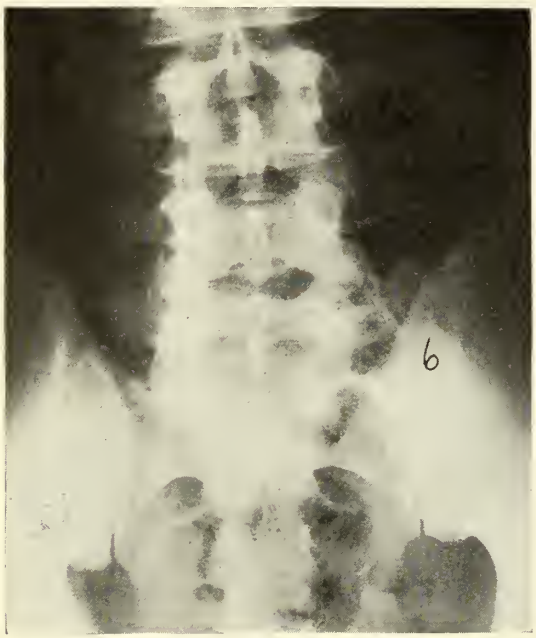

Fig. 3. Unilateral sacralization, with spina bifida occulta.

was present in 16 per cent of these cases. It was undoubtedly present in more of the cases, and accounted for limited motion and list, but was not noted by the examiner. Personally, I often find it difficult to ascertain with certainty in muscular and obese individuals unless supported by limited motion, list, or positive leg signs.

The straight-leg-raising-test was positive on one or both sides in 27 per cent of these cases. This test transmits leverage through the hamstring muscles to the patient's lower spine, and, if applied carefully, it is of great value in demonstrating muscle spasm. As the patient's leg is raised straight from the table, the examiner's other hand should be placed beneath the lower spine, where the reflex spasm can be felt concomitant with the onset of pain before the lumbar spine begins to move. In cases of unilateral sacro-iliac strain, this sign is positive at a lower elevation of the leg on the affected side than on the sound side, while in cases of lumbo-sacral strain, the sign is apt to be positive on both sides at the same elevation. This test is also valuable because it is difficult to simulate if carried out properly and carefully.

The cross-leg-rocking-test is valuable because it confirms information gained by the above tests. In this test, the knee is flexed so that the ankle rests on the opposite knee of the recumbent patient; then downward pressure is simultaneously applied to the flexed knee and the opposite pelvic spine. The psoas muscle and the Y ligament of the hip are thus utilized as a lever to rock the pelvis. Response to the test is complaint of pain, and being a subjective test, this is less reliable. However, the test is valuable because being less frequently employed, it is less frequently simulated. This test was positive, that is, produced complaint of pain, in 19 per cent of this series.

The other leg signs and sacro-iliac tests, such as crest compression, pressure over the symphysis pubis, Ely's sign, Gaenslen's sign, and palpation per rectum, were employed too seldom to be included in this analysis. They are, however, of great value in differentiating lumbo-sacral and sacro-iliac strains.

Tenderness was present in 66 per cent of these cases. As a sign it appeared most frequently, yet is probably of least value unless the examination be systematic and thorough. In palpating for tenderness the patient had best be placed prone over the end of the table so that his legs hang free. This position removes much of the lumbar lordosis and offers better opportunity for identification of bony landmarks. Tenderness is sought first over the sacro-iliac joints, then over the sciatic notch, next over the ilio-lumbar ligaments, next over the spinous processes and interspinous ligaments, and lastly over the dorsum of the sacrum. Points which seem to be sensitive are marked on the skin, and later checked to eliminate simulation.

Short leg presented in 2 per cent of this series, just frequently enough to remind one that measurement of the legs is a part of a complete examination of the back.

X-RAY FINDINGS

Every case in this series was studied with stereoscopic antero-posterior and lateral roentgenograms, and 80 per cent showed some sort

of so-called "congenital abnormality," or anatomic variation.

Abnormally placed postero-lateral articulations appeared in 63 per cent of the cases—too high a percentage to ignore or consider as coincidence. As mentioned above, nearly every patient having a list showed "abnormal" articulations. While the facets of these articulations between the fifth lumbar vertebra and the sacrum are somewhat crescentic, nevertheless the major portion of the articulation faces medially in the normal spine as pointed out by Goldthwait (Fig. 1.) In a large proportion of spines studied roentgenologically these small diarthrodial joints are seen to face more antero-posteriorly, and are called "abnormal," or variations (Fig. 2.) Dickson, Bohart, and others, studying large series of backs roentgenologically, report variations present in 35 to 44 per cent of all spines. In this series of 100 cases diagnosed "back strain," however, the percentage is much higher—63 per cent showing abnormal facets and 80 per cent some congenital variation. This seems adequate basis for reasoning that such backs are either more susceptible to strain, or recover more slowly from the effects of strain.

Sacralization appeared in 5 per cent of this series, either unilaterally or bilaterally. Spines having this variation are inherently weak because of the restriction of motion (Fig. 3.)

Spina bifida occulta occurred in 7 per cent of this series, and lack of fusion of laminae occurred in an additional 3 per cent. Persons having this variation are obviously more susceptible to strains, especially the muscular type, because the membrane closing the defect offers a weaker origin to the muscles arising from it. While spina bifida occulta is one of the commoner congenital variations and does predispose to strains, the injury occurring in these cases usually responds rapidly to treatment.

Fig. 4. Osgood back brace.

Fig. 5. Goldthwait back brace.

Scoliosis of a mild type was revealed by the roentgenogram in 2 per cent of this series. Except as this condition alters the statics of the spine slightly, it does not seem to figure prominently in predisposing to strain.

Sprain fracture appeared in 2 per cent of these cases, as a tiny chip pulled off the anterior margin of the vertebral body.

Arthritic changes were revealed by x-ray in 5 per cent of these cases. Insurance companies know this to be one of the most bothersome findings. "Pre-existing dormant arthritis, aggravated by injury" has become a common expression.

Antecedent disease such as healed tubercu-

losis, or healed fracture, was found in 8 per cent of these cases, a large enough proportion to suggest that the fusion of even a small portion of the spine constitutes a permanent disability which may slightly predispose to subsequent injury.

Fig. 6. Plaster-of-Paris jacket. (Note felt pad for axilla.)

TREATMENT

The various forms of treatment are applicable to widely different types of cases, and consequently the methods employed require explanation only in general.

Physiotherapy was employed in all of these cases either by the patient himself or a trained physiotherapist. Local heat, either by electric pad, radiant light, or hot packs was usually applied. Baking and massage was given in many cases, but none of this series happened to receive diathermia. We believe diathermia of great value in acute strains of all sorts, and find it of great value for relief of pain in such cases.

Rest alone (or supplemented by no other treatment than adhesive strapping) was used in 6 per cent of these cases. By this is meant absolute rest in bed, usually with pillows supporting the knees to relax the hamstring muscles. All of these patients, however, were instructed to avoid bending, stooping, and lifting during the period of treatment, and usually were cautioned to avoid the jolting of vehicles.

Foreign Protein Injections were employed in 2 per cent of the cases. This is done in those special cases where the arthritic habitus of the patient seems to warrant such treatment. It is always carried out in a hospital by a competent internist. In both of these cases this treatment seemed beneficial, but not entirely curative.

Correction of short leg was used in 2 per cent of the cases. The correction employed is a one-half inch lift on the outside heel of the shoe, adding the remainder necessary for correction by an inner heel. If the difference in length is more than three inches a high sole is employed.

Postural correction was given in 12 per cent of the series. Correct mechanical use of the body was explained to the patient; postural rests and corrective exercises were given. Some of these cases were recorded at the first visit with the Schematograph, and later gracings made from time to time to check progress.

Braces were used in 61 per cent of these cases. The type of brace varied from the leather sacro-iliac belt having perineal straps, to the Osgood, or "butterfly," brace having axillary crutches to take the weight on the iliac crests (Fig. 4). The brace most frequently used was the spring steel brace of the "Boston" or Goldthwait type (Fig. 5.) This is a highly efficient brace for the ordinary case, being quite comfortable if properly fitted.

Plaster of Paris jackets for more complete and certain immobilization, were employed in 8 per cent of these cases. Usually they were applied after manipulation under anesthesia and were worn during the period of rest in bed and after the patient was ambulatory. For cases of back strain they are always applied with the patient supine on the Goldthwait irons. Only very little padding can be used if jackets are to be efficient—just enough to protect bony prominences and not interfere with accurate fitting (Fig. 6).

Manipulation under anesthesia was used in 10 per cent of these cases. Ethylene anesthesia was employed, and only those cases having a list with possible mechanical derangements of joints were manipulated. We attempt to carry the spine through the normal range of motion with the muscle spasm relaxed by anesthesia.

The straight leg raising of Baer is used to flex the pelvis on the spine. This is not an exact method of treatment, but we have had no untoward results, and some brilliant results.

The operation of spinal fusion was done in 4 per cent of these cases. Naturally it is done only in severe, chronic cases, after all other forms of treatment have failed. The exact type of operation used is a modified Hibbs' operation, to be reported shortly. Usually the last three lumbar vertebrae are fused to the sacrum (in lumbo-sacral cases, no sacro-iliac fusion appeared in this series (Figs. 7 and 8). The results have been satisfactory to the patients in all of these cases thus far.

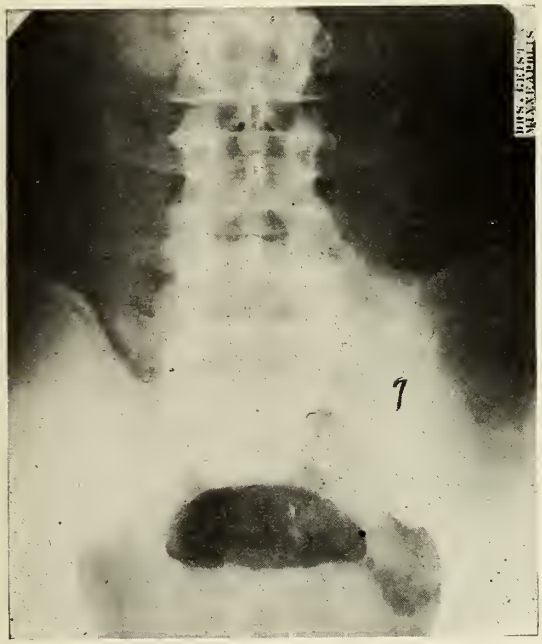

Fig. 7. Post-operative spine (in unilateral sacralization). (Same case as Fig. 3.)

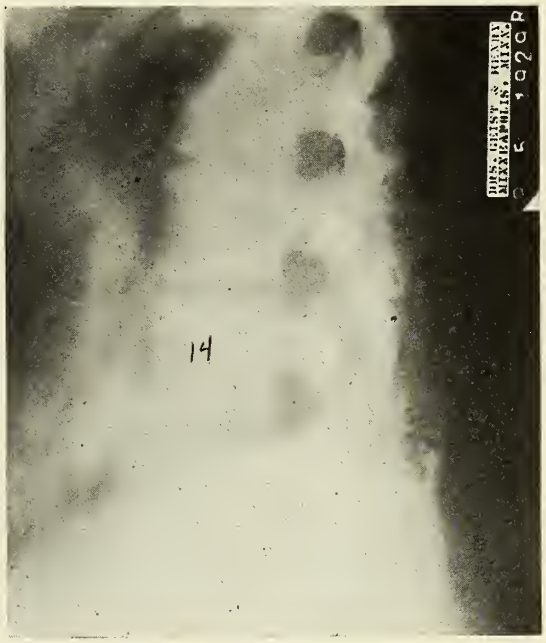

Fig. 8. Post-operative spine (note new bone formation 6 months post-operative).

RESULTS

An analysis of the results in these cases seemed at first disheartening, for the end results were unknown in 29 per cent. Many of these were patients involved in litigation, however, who were unable to utilize our report of opinion on their condition as they had anticipated. Undoubtedly, some of this unknown group sought relief elsewhere or were perhaps disgruntled or dissatisfied with the treatment received. Some of them were referred to charitable institutions, and some have moved.

In 71 per cent, however, the end results are at hand. Of these, 4 per cent are definitely unimproved to date. In two of these the condition seems to be recurrent, depending either upon the exigencies of their work or play.

At their last office visit 30 per cent of this series reported improvement but not complete cure. We believe that this group improved sufficiently later.

At their last office visit the remaining 30 per cent reported complete relief from their trouble.

SUMMARY

1. An analysis of 100 consecutive cases of back strain is given and a summary of the physical findings is appended herewith.
2. Back strains are most common in early adult life, and are usually due to external violence, although 25 per cent of this series gave no history of trauma.
3. A "list" of the spine is a very reliable sign, and is due to muscle spasm or mechanical derangement in anatomic variations of the lumbo-sacral joints.
4. Limitation of motion of the back, and the "leg signs," are valuable aids in diagnosis.
5. Congenital anomalies appeared in 80 per cent of the series, indicating that such backs are predisposed to strain.
6. Most cases were relieved by rest or mechanical support and fixation, although several required fusion operations to gain permanent relief.

CASE REPORTS

A CASE OF MYXEDEMA AND DIABETES*

JAMES B. CAREY, M.D.
Minneapolis

The combination in one person of myxedema and diabetes mellitus is apparently quite rare. Only four cases have been reported in the literature to date. One case was reported by Wilder,[1] in a child; one by Jamieson[2]; and two by Wright.[3] It is interesting to note that all of these patients either had the diabetes first, and subsequently developed myxedema, or the two conditions occurred simultaneously. In the case reported in this paper, the myxedema antedated the diabetes by six years.

Wilder's case was that of a child who had diabetes at the age of 15 months, and who subsequently became myxedematous at three years of age. The diabetes had been under very careful control, but when an attempt was made to raise the low metabolic rate, consequent to the myxedema, by the use of thyroid substance, the diabetes became more marked. But when thyroid substance was discontinued, in order to control the diabetes, myxedema symptoms returned.

This also seems to have been the experience of the other men who reported three cases, all of which concerned adult patients. Jamieson's case had a history of diabetes antedating the onset of myxedema symptoms, but when first seen and examined, both conditions were found to be present. The original sugar tolerance curve was fasting .131, 3 hours, .185. After 13 days, thyroid medication brought the original low basal metabolic rating up to normal; the sugar tolerance had diminished, *i.e.,* fasting .284, 3 hours, .343. Thyroid was discontinued for one week and the curve still remained high, .254 and .349 in 3 hours with a basal metabolic rate of —11%. Thyroid was further withheld for one month, reducing the basal metabolic rate to —41%, and the fasting blood sugar then had reduced to .192. A standardized procedure of diet, insulin and small doses of thyroid was then agreed upon; the attempt being made to keep the metabolic rate moderately low, and the blood sugar within reasonable bounds.

Wright's cases, also adult patients, are quite similar. In both cases the individuals had diabetes before the onset of evident myxedema. After the establishment of the myxedema, the diabetes was much more difficult to control, as Jamieson's and Wilder's experiences revealed.

REPORT OF CASE

A. W. S., male, aged 44 years, appeared for examination June 28, 1927, complaining of weakness, aching legs, and shortness of breath. He stated that in March, 1920, he began to feel general malaise, was easily fatigued, and had some aching of legs and dyspnea on exertion. He had been treated for pyorrhea at that time without relief of symptoms. Upon questioning it was brought out that he had suffered from impairment of visual acuity; his mental processes were considerably retarded; and his hearing, especially, had become quite poor. He found it almost impossible to keep awake, and would usually fall asleep anywhere if he remained in a sitting position for any length of time. He had gradually gained in weight, and his flesh had become soft. He had become stooped, and "round shouldered" during the past year, and experienced great difficulty in holding his head erect. His hair had become dry and had fallen out; his skin was dry, although he perspired readily. There had been some swelling of the legs from the knees down, which did not vary greatly on change of posture. His wife further stated that his pulse had become slow, being about 50 when she had counted it. The family and past history was unimportant. He had two children, and his wife had had two miscarriages, both at about six weeks.

Examination revealed a dry, scaling skin, thin dry hair, and scaly scalp. The face was puffy, especially around the eyes, and the color was rather pale. General musculature was flabby, with an increase of fat deposit at the back of the neck and on the abdomen. The pulse was slow (50-56), full in volume, but of low tension. Respiration was also slow. As the individual was questioned, his attention wandered; his speech was slow and thick, and his answers were often inaccurate when checked by his wife. The eyes were negative, except for a drooping of the upper lids. The examination as to heart, lungs, abdomen, was entirely negative. The reflexes in the extremities were sluggish. There was no true edema, but a typical myxedematous palpatory sensation of the subcutaneous tissue was present. The first blood pressure reading was 108/80. Important laboratory findings at this original examination were, a negative urine, a negative blood Wassermann, and basal metabolic rate of —36 per cent. He was placed on 6 gr. of dessicated thyroid substance daily, and his subsequent course can be readily seen by the accompanying chart. There was the expected symptomatic improvement, and from 1922 to 1928 he was not seen, although we corresponded with him at intervals.

During the winter of 1927, he developed symptoms of diabetes, that is, he lost weight rapidly, had great hunger, thirst, and weakness. The doctor in the town to which he had moved found sugar in his urine. There was great difficulty in establishing a proper balance between diet, glycosuria and thyroid dosage. Finally, in August of 1928, he returned to the Clinic for examination and management. At this time he was found to be thinner than before, and without any sign

*From the Department of Medicine of the Nicollet Clinic. Read before the Minnesota Society Internal Medicine, May 26, 1930.

or symptoms which one could identify as being myxedematous. His pulse rate was slow, his blood pressure 120/80, and his basal metabolic rate was —17 per cent. Again his course can best be followed by reference to the accompanying chart.

At the present time, the patient is not very coöperative, and insists upon an adequate daily food intake as he must continue his work as janitor. He will not report at regular intervals for checking up, but usually comes in when either he or his wife are worried about something.

Date	Basal Metabolic Rate Per cent	Wt. Kg.	Blood Sugar Per cent	24 hour urine sugar gram	Thyroid substance per day gram	Insulin Units Per Day	Diet
6/29/21	—36	75.8			6		General
10/ 3/21	—6	66.0			4-6		
4/ 3/22	+2	76.4			4-6		
8/28/28	—17	70.0	.174		4	15	Carbohydrate, 110 Protein, 70 Fat, 180
9/ 1/28				33	2	30	
9/14/28	+27	66.0		4	2	30	
10/ 5/28				3	2	30	
10/18/28	+7	69.0			2	30	
12/20/28	+12	67.0		13	2	30	
7/17/29	+1	58.0	.285		2	30	
3/31/30	+11	60.0	.222		2	30	
4/ 4/30				8	2	35	

Chart indicating patient's condition.

We have tried to eliminate the thyroid substance, thinking that perhaps the diabetes might be better controlled if we allowed the basal metabolic rate to drop to 10 or 15 below normal. The patient, however, has a great fear of relapsing into his previous lethargic state, and insists upon taking a small daily dose of the substance. During the time when he was first found to have diabetes, he had a few unfortunate insulin reactions, and has developed some fear of an over dosage of it. Perhaps, due to the peculiar combination of things, in this case, these personal factors are not very important, but they are recorded as a possible explanation for the difficulty in controlling the diabetic factor. If the basal metabolic rate could be allowed to drop below normal, and the man would consent to either limiting his food intake, or increasing his insulin dosage, perhaps the balance could be better maintained.

DISCUSSION

According to Joslin and others, diabetic patients when first seen usually present an increased basal metabolic state, about +20 per cent being average. This rate is generally reduced to —10 per cent or so after the patient is placed upon proper dietary management. It has been thought that this reaction is no more than a chemical metabolic effect of food.

Wilder has stated that the presence of the exophthalmic goitre syndrome reduces the ability of the diabetic individual to utilize carbohydrate, decreases the efficiency of a unit of insulin, and increases the danger of sudden onset of diabetic coma, while the control of the hyperthyroidism by iodine markedly improves the carbohydrate tolerance. These deductions, based upon observation of the behavior of diabetics with hyperthyroidism, must be applied to our present problem.

Fitz[4] had already found that a non-toxic goiter had no influence upon diabetes. Holst[5] has seen a diabetic condition occur after thyroidectomy on an exophthalmic goiter during a remission. Two and one-half years later this same patient became myxedematous, and the diabetes cleared up. Wilder[1] further states that there are numerous instances of myxedema occurring in diabetes, resulting in an improvement of the carbohydrate tolerance, but he does not state any specific cases other than those already mentioned, nor does he give further references. All of which seems to indicate that with low metabolic rate, the tissue cells are able to utilize a given amount of glucose with less insulin than they require when the metabolism is pitched at a higher rate.

Gardiner-Hill, Brett, and Smith[6] give blood sugar curves in 15 myxedema patients which are seen to reach a higher peak and to be more greatly prolonged than normal. In spite of this, glycosuria was rare in their studies. In general, the fasting blood sugar was normal. Thyroid extract given to these patients did not raise the fasting blood sugar, and the general effect on the curve itself was to lower the peak and quicken or shorten the curve.

Janney and Isaacson[7] found that the fasting blood sugar could be reduced in animals by removing the thyroid from them. Gray[8] found low blood sugar values in 8 cases of myxedema. Other authors quoted by these men confirm the same findings.

In conclusion it must be evident that when diabetes is present in an individual who has a low metabolic rate, one who is, in other words, myxedematous, the raising of that low rate by thyroid substance produces the same result upon the diabetes as occurs when a diabetic patient with a normal basal metabolic rate develops hyperthyroidism. What has not been evident before, but which seems to be brought out in the case presented, is that the presence of the diabetes also does something to the myxedma, that is, less thyroid substance is needed to maintain a normal metabolic rate after the onset of the diabetes than was necessary before.

1009 Nicollet Avenue.

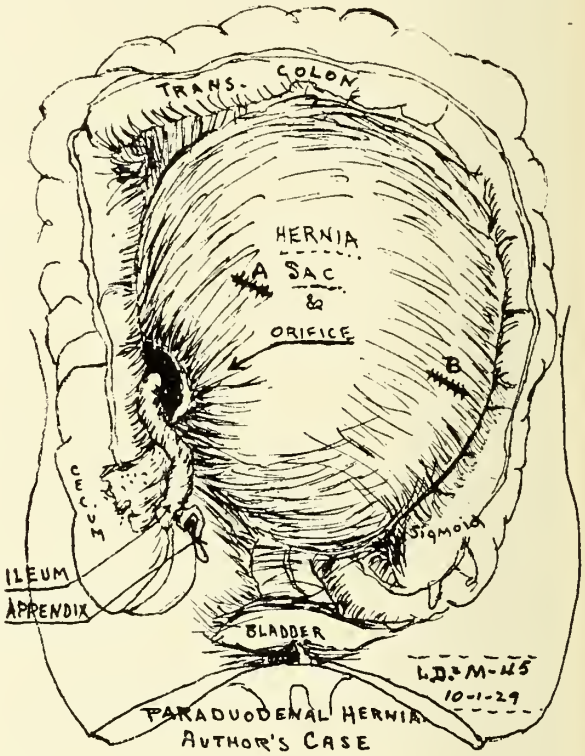
RETROPERITONEAL HERNIA



REPORT OF CASE

Fred H. Stangl, M.D.
St. Cloud, Minnesota

An investigation of the literature reveals that the incidence of retroperitoneal hernia is relatively rare, and that to date the total number of reported cases does not much exceed two hundred. These herniae may be divided into four groups, namely, duodenal, pericecal, intersigmoid and those through the foramen of Winslow.

The hernia here reported is of the paraduodenal type, which is the most common. This hernia was encountered in the course of a postmortem examination made for the purpose of locating bullet wounds of the abdomen. The individual was a forty-five year old male laborer who had never had any complaints which were referable to the presence of the hernia. Death resulted from bullet wounds of the abdomen which had caused shock, hemorrhage and peritonitis. A surgical repair had been attempted soon after the wounds had been inflicted but only the hernia sac had been sutured, the impression, according to the surgeon, being that the sac was hemorrhagic distended bowel.

At necropsy, when the abdomen was opened, it was found entirely void of small intestines and the major portion of the abdominal cavity was occupied by the large tumor mass as shown in the accompanying illustration. The membrane covering the herniated small intestines was neither transparent nor translucent and was made up of dense fibrous tissue from 5 to 7 mm. thick. When the cecum was pulled laterally, a small

portion of the distal ileum was found which coursed upward from the ileocecal valve to enter an orifice just at the side of the cecum about half way between the caput coli and the liver. Two recently catgut-sutured defects in the anterior hernia wall were encountered at the sites indicated by "A" and "B" in the illustration. Within the hernia sac the small intestines were much matted together by old fibrous adhesions and there was everywhere present much bowel content, dark purple fluid and clotted blood, and fibrino-pus. Several large lacerations were present in the loops of small intestine from which the content had escaped and where the hemorrhage had occurred.

EKA SALT AND THE SALT FREE DIET

Eka salt (claimed to contain sodium malate as its essential constituent) is offered as a means of giving the same flavor as common table salt without making it necessary for the body to deal with the ten or fifteen grams of sodium chloride that would ordinarily be taken. Since no one knows whether the sodium or the chloride is responsible for any of the untoward effects attributed to sodium chloride, it would not be proper to include Eka salt in a diet that is intended to be strictly salt free. (Jour. A. M. A., June 7, 1930, p. 1859.)

YEAST

Yeast has so uncertain a laxative effect that it is hardly justifiable to class it among the cathartics. It might more appropriately find a place among the laxative diet factors alongside bran, honey and prunes. Its content of vitamin B makes it of specific value in skin cruptions due to vitamin B deficiency, such as those occurring in pellagra. That it is of much value in other skin troubles, such as acne or furunculosis, is doubtful. The history of yeast suggests that it has a therapeutic value, but that this value is slight indeed. (Jour. A. M. A., June 14, 1930, p. 1939.)

NEW AND NON-OFFICIAL REMEDIES

The following articles have been accepted by the Council on Pharmacy and Chemistry:

CAREL LABORATORIES
Alpha-Naphco

ELI LILLY & Co.
Ampoules Glucose (Dextrose, U.S.P.) Lilly 50 Gm., 100 c.c.

TRUTH ABOUT MEDICINES

FOODS

The following products have been accepted by the Committee on Foods of the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in Accepted Foods:

Nouron (Nouron Products Corporation, New York).—The ingredients used in the manufacture are soy beans, whole wheat flour and egg yolk. It is claimed to be a nutritious, digestible and palatable food prepared especially for assisting in the gradual change from a liquid to a solid diet, as for weaning babies and for convalescents.

Merrell-Soule Whole Lactic Acid Milk Powder (Merrell-Soule Co., Inc., New York).—It is made from fresh whole milk. It contains fat, 28 per cent; protein, 26.5 per cent; lactose, 32.5 per cent; mineral matter, 6 per cent; total acidity, 5 per cent; free lactic acid, 4.25 per cent; moisture, 2.25 per cent. It is prepared from pure whole milk inoculated with a culture of *Streptococcus lactis.* This product is claimed to have the value of freshly prepared lactic acid milk.

Jell-O (The Jell-O Co., Inc., Le Roy, N. Y., General Food Corporation, Successor).—A mixture of pure gelatin, cane sugar, pure fruit flavor, fruit acid from grapes and vegetable color.

Carnation Milk (Carnation Milk Products Company).—Cow's milk reduced to consistency of cream by evaporating in vacuum and then sterilizing. It contains the vitamins that any cooked milk is depended on to supply.

New Oata (Ralston Purina Co., St. Louis).—It contains rolled oats and precooked rolled wheat. It is claimed to provide iron, phosphorus and the constituents of these grains in a form permitting rapid cooking.

Purina Whole Wheat Flour (Ralston Purina Co., St. Louis).—It is composed of whole wheat. It is claimed that the product is rich in iron, phosphorus and other minerals.

Checker-Corn Flakes (Ralston Purina Co., St. Louis).—It is claimed to provide flavor and variety appealing to the appetite.

Ralston Wheat Flakes (Ralston Purina Co., St. Louis).—It is composed of whole wheat, claimed to provide nourishing food in appetizing form.

Ralston (The Whole Wheat Cereal) (Ralston Purina Co., St. Louis).—It is choice hard winter wheat, containing the wheat embryo, with its vitamins. It is claimed that the whole wheat berry supplies the elements for healthy growth. (Jour. A. M. A., June 14, 1930, p. 1919.)

MODILAC NOT ACCEPTABLE FOR N. N. R.

The Council on Pharmacy and Chemistry reports that Modilac is the proprietary name under which the Wm. S. Merrell Co. markets a compressed tablet containing milk sugar and some salts, recommended for the "humanizing" of cow's milk to render it suitable for infant feeding. In 1925 the Council held Modilac not to be within the scope of New and Non-official Remedies because no medicinal claims were made for it, and included the product in the list of exempted articles. From an examination of the present advertising it appears that medicinal claims are now being made for the product, thus bringing it within the scope of New and Non-official Remedies. These claims were found to be unacceptable and therefore the Council voted that the exemption of Modilac be rescinded and that it be considered unacceptable for New and Non-official Remedies because it is an unscientific mixture of official articles marketed under a nondescriptive proprietary name and with unwarranted therapeutic claims. (Jour. A. M. A., March 8, 1930, p. 716.)

President's Letter

THE big state meeting has come and gone. All who took an active part in contributing to its success are, we may be sure, glad of the chance to relax. They are thinking, quite in unison with everyone else, that this is vacation time, the good old summer time.

Doctors need periods of relaxation and recreation rather more, perhaps, than people in other fields of work, for their responsibilities are more numerous, more direct, and the tension under which they live is greater than is the case in most other callings. Few people realize that the doctor is something of a prisoner with many wardens, to each of whom he is responsible. Never may he be out of reach; always he must be subject to call. The feeling of being tethered makes him long for vacation freedom. His thoughts at this season instinctively turn, in spirit if not in fact, to that first of all great anglers, Izaak Walton.

Occasionally a babe is born into the world whose name is destined to live in the minds of posterity over long periods of time. Some of such are remembered because of the exercise of great power, usually in connection with affairs of state, exercised for weal or woe. Others are remembered because of contributions to science or discovery, or because of unusual philosophical genius. The ones who are remembered best and longest are they who have contributed notably to the real betterment and happiness of mankind.

We all contribute something to life as we journey through, but he whose name endures over the brief span of one hundred years is an exception. Therefore when we find a name that has lived upwards of three centuries it arouses our interest.

The name of Walton comes to mind again in this connection. He was born in the last decade of the 16th century and he lived to the ripe old age of ninety years. He appears to have been a man of considerable acumen, for he was able to retire from gainful work at the age of fifty-one. Thereafter he devoted much of his time to fishing and some of it to writing. Evidently he was not a very ambitious man, as we would define that term today. The few biographies he wrote, of his contemporaries, would hardly entitle him to lasting fame, yet his name endures, due, no doubt, to his one masterpiece, "The Compleat Angler, or The Contemplative Man's Recreation." As we read this book we learn, without realizing it, to know what kind of man he was. We come to feel intimately acquainted with him, and with his fish, and with the scenes of his activities. We feel the warmth of a sunny disposition. He knew the value of rest and recreation, of time used for cultural purposes. He loved beauty, and he enjoyed life in the truest sense. The message he gave to posterity was one of beautiful pen pictures of natural scenes, a quaint philosophy of simple life, the joy of friendly conversation, the value of earnest endeavor and the importance of happy understanding.

This celebrated fisherman would have made a great doctor, for he knew the needs of both body and mind and he understood the yearnings of the human heart. He loved to meditate and he was truly a great philosopher. We doctors may well turn to him to learn something of how to fill our lives, and the lives of others, with happiness.

This is vacation time and we continue to go about our accustomed work, fettered by duty. We all should heed the message his voice is whispering across three hundred years of time: "Go fishing! And learn to be a philosopher."

S. H. Boyer

President,
Minnesota State Medical Association.

Vol. XIII August, 1930 No. 8

ETIOLOGY OF THE COMMON COLD

Newspapers have announced that J. A. F. Pfeiffer of the University of Maryland School of Medicine has discovered the cause of the common cold. Before this announcement Dr. Pfeiffer had written two short preliminary reports[2, 3] on an organism that he believed to be the cause of colds. It seems likely that the notice in the newspapers is concerned with the same organism. If so, it is a Gram-positive coccus with cultural characteristics that distinguish it from other cocci. It is said to produce colds in man and animals experimentally, to cause fixation of complement in high dilution, and to produce immunity through vaccination.

It should be pointed out, however, that even though one organism can be shown to produce the symptoms of the common cold, other organisms may, also, produce them. There are strong reasons for believing that the common cold represents merely a non-specific reaction to infection of the nasal mucosa with a number of different organisms. Among the reasons for holding this view are several facts. Different symptoms accompany different epidemics of colds. One may be characterized by headache, another by extreme prostration, another by earache, and still others by bronchitis or neuritis. The complications may vary similarly. One season brings infection of the mastoid processes, another, disease of the nasal sinuses, and another, albuminuria. Perhaps the strongest argument for multiple origin is to be found in the results of bacteriologic examination of the complicating lesions. For instance, otitis media complicating colds in the head may yield pure cultures of streptococci, pneumococci, Friedlander's bacilli or any one of several other organisms. The predominating organisms in colds have been studied in different seasons and in different places. They vary markedly.[1, 4] The nasal mucosa may be infected by the organisms of diphtheria, scarlet fever, measles, influenza and epidemic meningitis. Were it not for symptoms elsewhere in the body, these serious illnesses would be only severe colds. Conjunctivitis may be caused by the streptococcus, the pneumococcus, the staphylococcus, corynebacteria, the Koch-Weeks bacillus and the Morax-Axenfeld organism. It scarcely seems reasonable to suppose that the milder nasal infections are all caused by a single coccus.

If Pfeiffer has discovered the only cause for the common cold, he has made one of the most notable discoveries in modern medicine. If his organism proves to be only one of the causes, nevertheless he has made a valuable contribution.

SAVING THE TAXPAYERS

"When a hospital is owned and operated by government and supported by taxation, to which the medical profession contributes its due proportion, medical attendance should be paid for by taxation, along with all the other facilities supplied by the institution."

The above quotation from the address of the President-elect of the American Medical Association, Dr. William Gerry Morgan, at the Detroit session, seems reasonable. The precedent, however, seems to have been established that physicians donate their services to state and city tax supported institutions and consider the time and effort donated fully compensated by the increased experience gained. Whether the profession in any locality decides to act on the suggestion quoted above and to cease donating its services, depends on the feeling of the physicians in any particular locality.

In an effort to lighten the load of hospital maintenance to taxpayers, certain city and state hospitals in Minnesota have added the part-pay system whereby the patient pays for his hospital care at a rate commensurate with his ability to pay. The rate varies from $4.00 per week up. The services of the staff physician are thus donated to an additional group of patients who can only pay for hospital care or some fraction thereof. This group is one that is likely to grow and in certain instances has grown to such an extent as to add considerable to the sum total of patients treated gratis.

Not to seem penurious we fail to see why physicians should extend their charity to include the part-pay hospital patient in order to save the taxpayers (physicians included) what amounts to thousands of dollars annually.

There are other phases of the situation which lead only to confusion. The part-pay patient's stay in hospital is a matter of financial concern to him, a matter which the attending physician is likely to overlook. His next-door neighbor is receiving the same hospital care at no cost.

The distinction between the indigent patient and the pay patient should be sharply drawn. The matter should be taken up by the local medical society unit concerned, as the continuation of the practice lies in its hands.

PREVENTIVE INOCULATION AGAINST DISEASE

The progress in the immunization against disease has been made so rapidly that it is well to take stock and determine what procedures have been definitely proven of value, what measures are still in the experimental stage, and what measures that promised well have been definitely abandoned.

In any program of this character it is important to emphasize that the prevention of smallpox by vaccination is still the outstanding contribution in this field. Vaccination alone accounts for the fact that we no longer have smallpox constantly in our midst and by vaccination alone can we continue this state of affairs. All infants should be vaccinated between the sixth and twelfth month of life and this should be repeated every five to seven years thereafter. The vaccination should be done by pin prick, then a drop of vaccine placed in the skin, then wiped off and no covering or bandage of any kind applied.

Second only to smallpox have been the results obtained by the preventive inoculation against diphtheria. Diphtheria antitoxin is administered to neutralize the toxin formed by the bacillus in the body of the patient. It has a restricted use for temporarily protecting susceptibles in close contact with the disease. This passive immunity is temporary and does not last over three weeks.

By means of the Schick test, it is possible to determine susceptibility to diphtheria. When the individual is immune a small amount of diphtheria toxin introduced into the skin produces no reaction and the skin appears normal after one week. When the individual is susceptible there remains one week after inoculation a definite red scaling area and often indurated. An immune mother transmits to her offspring sufficient antitoxin to protect it for a number of months, after which period practically all infants are suscep-

tible. As the number of deaths from diphtheria are greatest in the early years of life, it is very important that preventive diphtheria inoculation be carried out before the end of the first year of life. By giving three inoculations of diphtheria toxoid (which is a modified toxin), at intervals of two weeks, from 95 to 98 per cent of susceptible individuals are protected against diphtheria. The use of toxoid in place of toxin-antitoxin does away with the danger of sensitizing the child to horse serum.

Vaccination against smallpox and immunization against diphtheria are so well recognized as preventive procedures that it is as much the duty of a doctor to protect his patients against these two diseases as it is to treat a patient sick with pneumonia or nephritis.

More recently the cause of scarlet fever has been discovered and the toxin producing the rash and toxic symptoms demonstrated. The toxin is produced in the throat of the patient by the streptococcus scarlatinæ. By immunization of horses with this organism and its toxins an immune serum (antitoxin) has been produced which, if given in the early stages of scarlet fever, has a striking curative affect. By the use of this antitoxin the mortality in severe scarlet fever has been very definitely reduced. The incidence of scarlet fever in susceptible individuals is so low that antitoxin should not be used to prevent the disease, but used only in severe cases of the disease.

In determining susceptibility to scarlet fever, the soluble toxin, produced by the streptococcus scarlatinæ grown in plain broth, is used. A small amount is injected into the skin just as in the Schick test. A red indurated area after 24 hours usually indicates susceptibility to the disease and no reaction usually indicates immunity to the disease. The negative test in the newborn infant is not dependent on antitoxin transmitted from its mother as in diphtheria.

For temporarily immunizing the inmates of an institution or school to prevent the spread of scarlet fever active immunization has been successful.

Until a longer interval has elapsed and we can be sure of the permanence of the immunity, it does not seem advisable to recommend the use of active immunization against scarlet fever as a public health measure.

Up to the present time the cause of measles is not definitely known; whether it be a streptococcus or filterable virus is still an open question. Degwitz has shown that if 5 c.c. of the blood serum of a patient who has recently recovered from measles is injected into a susceptible individual not more than four days after exposure to measles, the patient will be protected against measles for a period of about three weeks. If a boy is injected on the day that his sister comes down with the measles he is protected against the disease provided this is the only source of exposure. The same result can often be achieved with 10 to 15 c.c. of serum from any adult who has had measles. More recently the procedure has been changed in an attempt to modify rather than prevent measles. The resulting mild case of measles brings permanent immunity. Although it is not always possible to determine the exact time of exposure, the ideal time to give the serum is from six to seven days after exposure. It is of particular importance in preventing measles in the pre-school period. If the older brother or sister has come down with the disease, the right time to immunize the younger children is usually from one to two days after the measles rash breaks out in the older child.

The disease which, at present, is most difficult to control is whooping cough. Immunization against the disease and therapeutic infection with the Bordet Gengou bacillus has been extensively advised. The result must still be put in the not proven class. Some recent carefully controlled work does not indicate that either the prophylactic or the therapeutic injection is of any great value.

H. F. Helmholz, M.D.

THE SALE OF SUNSHINE LAMPS TO THE PUBLIC

The Council on Physical Therapy has taken the stand that a sunshine lamp sold directly to the public should be so constructed that the radiant energy emitted shall not differ essentially from sunlight. Furthermore, the advertising and descriptive matter pertaining to such lamps should contain no curative claims nor mention of specific diseases. The Council believes that the advertising should be more conservative: it is not convinced that human beings in health require the great amount of ultraviolet energy one is lead to believe is the case from the advertising pertaining to some of the so-called sunlamps sold to the public. (Jour. A. M. A., June 14, 1930, p. 1918.)

A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION

Medical Statesmen

Is the doctor alive to his great need for aggressive, organized action? Is he ready to assume the leadership for which he alone is qualified to take the responsibility?

The 1930 meeting of the House of Delegates of the Minnesota State Medical Association indicates that the doctor in his organization is indubitably becoming statesman as well as healer and diplomat as well as researcher.

Veterans' legislation, public health, economic tendencies, as they affect the question of caring for the sick; the protection of the layman from the unscrupulous machinations of quacks, of defenseless students against fraudulent educational enterprises; the workings of the courts as they relate to the mental and physical health of offenders within their jurisdiction, health education by newspaper, radio and speakers—all these concerned the 56 members of the House of Delegates at the 1930 meeting as intimately and vitally, apparently as the traditional and special business of the profession.

Following are some of the interesting medico-humanitarian suggestions made by doctors for doctors on the floor of the House, and the men who made them.

Dr. C. B. Wright, Minneapolis: "While the economists are struggling with the difficult problem of the high cost of medical care, we can help to solve it materially, by helping our patients to cut down the loss of time due to sickness; by shortening hospital stays and promoting the convalescent home for the convalescent; by public health education which will assist our patients to avoid illness and to resist the lure of patent medicines which still, according to the best statistics available, consume more than twice as much of their income as doctors' fees."

Dr. O. E. Locken, Crookston: "We must be frank in our public health work. We shall not be obliged to force our conservative public health program down the throats of the laity if we inform them adequately first."

Dr. E. A. Meyerding, St. Paul: "A system for a government disability insurance policy by which the war veteran could choose his own doctor and his own hospital in case of illness would relieve the government of the vast burden of hospital building its present scheme for veterans' care involves. It would utilize the empty beds which are already the serious problem of every civilian hospital and thus lower the cost of hospital care to everybody and at the same time, preserve his self respect and right of choice to the soldier."

Dr. E. M. Hammes, St. Paul: "The committee on Medico-Legal Affairs strongly urges the creation of a psychiatric service which may be at the disposal of the courts for every juvenile case, no matter what its nature and to function before condition of every felon. It is necessary protection to the offender and to society as well. On the one hand, many of them are in need of medical care instead of punishment. On the other, lacking such a service, many mental cases are released at the expiration of their prison terms entirely free and as great a menace to society as before they were sentenced."

Dr. A. C. Schulze: "There are three classes of schools for laboratory technicians in Minnesota. The University courses offered at the hospitals are all of them adequate, thorough and reliable. The commercial schools, in several cases, offer only a six months course, with inadequate teaching facilities and instructors. One of these charges $215 for a six months course, the other $250. They carry on a remarkable program of advertising and promise excellent positions. On the strength of the promises and the short course these commercial schools have proven very attractive. There is practically no limit to what they can do and remain within the laws of Minnesota. Physicians should inform themselves thoroughly about these schools.

"Certainly no institution teaching medical technology can expect to have the endorsement of organized medicine that does not have at its head a director who has the title of M.D. or whose teachers are not registered technicians; that has not sufficient physical equipment to properly carry on this work and is not actually connected with a hospital for the purpose of securing clinical material; whose course is not at least 12 months long or that is openly commercial or carries on pernicious advertising."

OF GENERAL INTEREST

Dr. H. L. Huffington, Mankato, has returned from a vacation trip to northern Wisconsin.

Dr. Roland E. Nutting, formerly with the Mayo Clinic, is now located in Duluth, Minnesota.

Dr. Anderson C. Hilding, formerly of Duluth, Minnesota, is now associated with the Mayo Clinic.

Dr. John F. Madden has announced the opening of offices at 842 Lowry Medical Arts Building, Saint Paul.

Dr. Joseph N. Gehlen, formerly associated with Dr. Hensel, recently opened an office at 642 Lowry Medical Arts Building.

Dr. M. I. Howard of the Mankato Clinic, Mankato, has resumed practice following a vacation spent in southern Minnesota.

Dr. C. A. McKinlay was called to Wichita, Kansas, July 17, because of the death of his father, Mr. L. McKinlay, of that city.

Dr. John J. O'Hara of Janesville has returned to his practice following an illness which confined him to the hospital for several weeks.

Dr. W. P. Crane left the Ancker Hospital July 1, after completing his internship, and will practice with his father, Dr. G. H. Crane, at Holstein, Iowa.

Dr. H. T. Petraborg of the University of Minnesota, class of 1929, has become associated with Dr. W. R. Humphrey in practice at Stillwater, Minnesota.

Edward Bratrud, F.A.C.S., of Warren, Minnesota, was elected to membership in the American Urological Society at a recent meeting held in New York City.

Dr. Edward C. Gibbs has become associated with Dr. Charles N. Hensel in the practice of internal medicine with offices at 1014 Lowry Medical Arts Building, Saint Paul.

Dr. P. D. Ward took up his duties as superintendent of the Miller Hospital, Saint Paul, July 1. Dr. Ward was formerly assistant director of the Albert Merritt Billings Hospital, Chicago.

Dr. Richard M. Johnson, formerly a graduate fellow in the Department of Medicine, University of Minnesota, is now affiliated with Dr. A. E. Olson and Dr. C. E. Alexander of Duluth, Minnesota.

Dr. George B. Weiser, New Ulm, was recently elected the new president of the Minnesota State Board of Medical Examiners. Dr. E. J. Engberg, Saint Paul, was elected secretary to take the place of the former secretary, Dr. E. T. Sanderson, Minneota.

Information has just been received that Dr. Thomas P. Noble, formerly in orthopedic surgery in the Mayo Foundation, has recently returned to Great Britain after three years of service in the Medical School of Chulalongkorn University at Bangkok, Siam, and has just been appointed by the King of Siam for three years as head of the surgical service of the Siamese government.

Dr. Richard Everingham Scammon, Professor of Anatomy at the University Medical School, has been appointed Professor of Anatomy at the University of Chicago. Dr. Scammon came here from the University of Kansas in 1911 as associate professor, and became full professor of anatomy in 1914. He has interested himself particularly in the anatomy of the growth of children and has published two books on the subject.

Quoting from the A. M. A. Journal of July 5, 1930: "Some eighteen names of physicians in the United States have been proposed for Affiliate Fellowship and approved by the Council of Scientific Assembly." The following seven are from Minnesota:

Dr. Herbert Davis, St. Paul; Dr. G. Deziel, Minneapolis; Dr. Geo. McIntyre, Minneapolis; Dr. Jennette McLaren, St. Paul; Dr. H. S. Nelson, Minneapolis; Dr. W. C. Portman, Jackson; Dr. W. H. Robilliard, Faribault.

Dr. Clarence M. Jackson, Director of the Institute of Anatomy at the University of Minnesota, and Dr. Richard E. Scammon, Professor of Anatomy at the University, have been honored by the selection of a symposium to which they contributed as the August "book of the month" by the Scientific Book Club. The book is *The Measurement of Man,* a study in biometrics which will be published by the University of Minnesota Press early in August. The late Dr. J. Arthur Harris, who was head of the Minnesota Botany department, and Dr. Donald G. Paterson, professor of Psychology, are the other authors contributing to the volume, which is the first Minnesota book to be selected as a "book of the month" by any book club. The essays in this symposium were originally lectures delivered at the university under the auspices of Sigma Xi.

It was formally resolved by the House of Delegates at the annual meeting of the State Association in Duluth to recommend Dr. Robert Emmett Farr, Minneapolis, for the next Nobel prize in medicine. Dr. Farr's work in the development of local anesthesia and anesthesia of the phrenic nerve has been individual, brilliant, and far reaching. It wholly merits, in the opinion of the house as expressed in the resolution, the most distinguished world recognition. In the absence of Dr. Farr, who is ill in Minneapolis, an important paper in which he outlined the principles involved in administration of local anesthesia was read by Dr. W. N. Graves, Duluth, as a feature of the symposium on anesthesia Wednesday morning. Two extraordinary moving pictures made by Dr. Farr himself, more than sixteen years ago when teaching, and demonstration by means of films, were shown by Dr. Stanley Maxeiner, Minneapolis, following the paper.

CONSULTATION BUREAU

Wm. A. O'Brien, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question.*—I would like to have your opinion on the etiological probabilities of a type of dermatitis which we have been encountering in bakery workers. The skin lesions present classically the pictures of the moist eczematous lesions of the usual chronic type, practically without exception occurring on the forearms but in some cases more widely distributed. I have made an effort to eliminate certain factors and, so far, have been unable to reduce our field to any single agent.

   Answer.—The following information has been secured about baker's dermatitis. Three suggestions were offered:

   1. That it is due to the excessive use of soap and water, keeping the hands and arms clean.
   2. That it was related some way to the materials used in the bakery.
   3. That it was coincidence.

   In order to determine the cause, it will be necessary to try skin tests. Select some of the common flours used, and apply them under oiled silk to the arms. It will be necessary to leave it on for at least 48 hours before the negative can be determined. Another method is to scarify the skin and put some of the powder on it. This gives an immediate reaction and can be read in 15 to 20 minutes. It is also possible to buy from many of the supply houses the common antigens, (flour, wheat, etc.). Not long ago an article appeared, stating that many of the occasional dermatoses were due to soap and water. It would be advisable to also consider it from this angle.

2. *Question.*—I have a patient, male, 56, who is having some difficulty in starting the flow of urine, frequency and burning. There is no history of venereal diseases. Residual urine by catheter after emptying the bladder amounts to 2 ounces. Prostate enlarged, irregular and sensitive to touch. Every time I massage the gland even so gently that it doesn't cause any pain in the prostate, the patient complains of a sharp pain, like a "toothache" at the end of the penis. What is the explanation? There must be some nervous connection between these two regions.

   Answer.—The enlargement is probably due to benign hypertrophy or prostatitis. The pain which is brought about by massage is apparently due to the inflammation or stone in the gland. Low ureteral pain is reflected to the end of the penis. Pressure on the prostate undoubtedly produces this reflex. The reason for the pain is the union of nerves from these two centers. What does the cystogram show and is there any evidence of ureteral stone in the lower portion?

3. *Question.*—Female patient, age 76, fairly well nourished, has lost 20 pounds the past two months and is lemon yellow color. Has been treated for double mitral and aortic lesion with decompensation for six months. Some edema of legs and some tingling. B.P. 120/0—apparently not decompensated now. Hemoglobin is 30 per cent. She has had recurrent attacks of vomiting, with temperature during the day or two it lasted. I feel a tender mass in the liver-gastric area which I regard as malignancy, as the outer portion of the liver does not seem to be enlarged as we would expect with a passive congestion. No dyspnea. The patient looks like she has carcinoma of the stomach. Have not checked the stools yet, but no blood in the vomitus. Unable to get patient for X-ray. Red smears show marked hyperchromasia, anisocytosis and poikilocytosis.

   Answer.—The smears are characteristic of pernicious anemia. It is possible that your patient also has carcinoma of the stomach. The blood change in both diseases may be identical. Both types of anemia may respond to liver treatment. I would advise that you start large doses of liver extract at once. We have seen remarkable responses as far as anemia is concerned in carcinoma of the stomach. When her heart condition improves, it would be advisable to move her and examine the stomach with the *x*-ray. Carcinoma of the stomach may be a local disease for a long time and if she has the condition, operation is indicated.

4. *Question.*—What is the best treatment for a pigmented nevus on the lower eyelid?

   Answer.—A pigmented nevus of the lower eyelid may be treated with carbon dioxide snow, radium, or radium emanation (radon), actual cautery, or surgical excision. The chief objection to carbon dioxide snow is the inability to localize the treatment. The eyelid usually swells and is rather painful. Radium or radium emanation may be used by protecting the cornea with a lead shield, which fits behind the eyelid. It is usually coated with paraffin and the eyeball desensitized with novocain. The actual cautery or surgical excision may also be used. Radium, or radium emanation, seems to be the treatment of choice.

5. *Question.*—I have a patient with anemia. Has occasional sore tongue, not suggestive, however, nor is there convincing evidence of atrophy. Gastric symptoms are absent as well as neurological. Hemoglobin is 35 per cent. R.B.C.s count 1,480,000. No foci of infection can be found, although I insisted on an extraction of an old root. The dentist said it was not abscessed. Patient has a tooth in which pulp cavity has become devitalized. The blood shows anisocytosis, poikilocytosis, and polychromatophilia. There is an excess of the large cell forms.

   Answer.—The smear is compatible with pernicious anemia. Have you done a gastric expression and determined the acidity? Check your neurological again. If no physical cause can be determined for the anemia, I believe that liver treatment, three or four vials of the extract daily, should be used without making a positive diagnosis of pernicious anemia.

6. *Question.*—I have a case of ulcerative colitis of about 6 weeks' duration. The stools are not sanguineous any more but the diarrhea persists and there is a gradual emaciation. What is the latest treatment for this type of a case? What is the status of Bargen's serum and where could it be obtained?

(Continued on following page)

OBITUARY

Arthur A. Law

1872-1930

Dr. Arthur A. Law was born at Harvard, Illinois, in 1872. After attending Shattuck Military Academy at Faribault, Minnesota, he took his medical training at the University of Minnesota Medical School, where he graduated in 1894.

During the Spanish-American war Dr. Law served as Lieutenant in the Medical Corps with the Thirteenth Minnesota Regiment and saw active service in the Philippine insurrection.

Early in his medical career he became identified with the Surgical Department at the University Medical School, and as Associate Professor of Surgery devoted much of his time to the University until his resignation a year ago on account of ill health.

With the rank of Lieutenant Colonel and as commanding officer of Base Hospital No. 26, the University of Minnesota Medical Unit, Dr. Law again gave valuable service to his country and at the close of the war was cited by General Pershing for exceptional meritorious and conspicuous service.

In 1922 Dr. Law became especially interested in thoracoplasty, in the surgical treatment of pulmonary tuberculosis and operated extensively at Glen Lake Sanatorium.

He was a member of the American, Western, International and Southern Surgical Societies, founder of the American College of Surgeons, a member of the Minnesota Academy of Medicine, besides being a member of Hennepin County, Minnesota State Medical Association and the American Medical Association. He was also a member of the Minneapolis, Minikahda and La Fayette Clubs, and of St. Mark's Church.

Dr. Law married Helen Elizabeth Lougee, by whom he is survived. His two daughters, Mrs. James G. Fullerton, Jr., and Mrs. John McD. Webb, of Minneapolis, and his mother, Mrs. Eva Ayer Law of Tacoma, also survive him.

Dr. Law's ingratiating manner and real love of humanity gained him a wide circle of friends and his name will long be identified with the leaders in surgical activities, not only in this state but throughout the country.

(Continued from page 588)

Answer.—It would be advisable to find the cause of your patient's diarrhea. Send a stool specimen to the Laboratories of the State Board of Health, on the campus. They furnish special containers for this purpose. The chances are that the patient is suffering with so-called nonspecific ulcerative colitis. Ileostomy is recommended before the patient emaciates too much. A bland diet, bed rest, transfusions for anemia, and subcutaneous fluid are used. There is a tendency toward remission. A few cases have lived for many years. Dr. J. A. Bargen, Mayo Clinic, would be very glad to inform you about the present status of his serum, and as to where it may be obtained.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 10:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and St. Paul (810 kilocycles or 370.2 meters).

The speaker is William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of August will be as follows:

August 6—Poison Ivy.
August 13—Knock Knees and Bow Legs.
August 20—Cause of Fever.
August 27—Cancer of the Stomach.

The annual meeting of the Southern Minnesota Medical Association will be held August 25, at Mankato, Minnesota. It will be a one-day session and an innovation is being tried this year in that the morning session is given over to clinical demonstrations and clinics.

On account of the type of demonstration on spinal anesthesia, it is necessary to have this demonstration at St. Joseph's Hospital at 8 o'clock.

The Teachers' College building with five class rooms equipped with blackboards, lantern slide projectors, and machines has been made available. This lends itself exceedingly well to clinical demonstrations and clinics.

Lunch will be served at the Teachers' College building, and the banquet will be held at the Mankato Country Club.

A feature of the morning session is the presentation of interesting case reports by various men throughout southern Minnesota. An hour and a half will be given over to that. It is hoped that as many men as possible will bring reports of interesting cases they have seen for discussion.

PROGRAM

MORNING SESSION

8:00 o'clock—St. Joseph's Hospital

Clinical demonstration of spinal anesthesia.
W. C. STILLWELL, M.D., Mankato.
Discussion: C. F. McCUSKEY, M.D., Rochester.

9:00 o'clock—Teachers' College Building

Clinical sections and demonstrations will be held in the class rooms.

9:00 A. M. Clinical demonstration of varicose vein injection and treatment.
C. F. DIXON, M.D., Rochester

9.00 A. M. Clinical-pathologic demonstration.
W. A. O'BRIEN, M.D., Minneapolis.

9:00 A. M. Hematology demonstration.
F. J. HECK, M.D., Rochester.

10:30 A. M. Pediatric clinic.
R. N. ANDREWS, M.D., Mankato.

10:30 A. M. *X*-ray demonstration.
L. G. Rigler, M.D., Minneapolis,
J. D. Camp, M.D., Rochester.

10:30 A. M. Uroselectan: Indications and uses.
E. P. Cathcart, M.D., Rochester.

11:30 A. M. Unusual case reports. Discussion led by:
W. A. O'Brien, M.D., Minneapolis.

1. Hemachromatosis.
J. J. Heimark, M.D., Fairmont.
2. Fat embolism.
A. L. Vadheim, M.D., Taylor.
3. Congenital pyloric stenosis.
B. J. Gallagher, M.D., Waseca.
4. Malignant tumor: Meckel's diverticulum.
L. S. Faust, M.D., Rochester.
5. Vicarious menstruation.
W. C. Bernstein, M.D., New Richland.

(Others to be announced later.)

12:30 o'clock. Luncheon and business meeting at Teachers' College Building.

AFTERNOON SESSION

1:30 o'clock—Auditorium of Teachers' College Building

The Art of Medicine.
W. C. Alvarez, M.D., Rochester.

Coronary disease with special reference to acute coronary accidents, their recognition and treatment.
H. W. Rathe, M.D., Waverly, Iowa.

Acute surgical conditions of the abdomen, their diagnosis and treatment.
Author to be announced later.

Hypertension: Case report of unusual vascular disease.
Charles Koenigsberger, M.D., Mankato.

Backache from the orthopedic viewpoint.
R. K. Ghormley, M.D., Rochester.

The prostate gland in a general examination.
A. E. J. Sohmer, M.D., Mankato.

Treatment of Bright's disease.
Moses Barron, M.D., Minneapolis.

Non-myxedematous hypothyroidism.
C. H. Hensel, M.D., St. Paul.

Epileptic seizures, their relationship to brain tumor.
H. L. Parker, M.D., Rochester.

The importance of toxic goiter complicating or complicated by other conditions requiring surgical interference.
C. W. Mayo, M.D., Rochester.

Appendicitis. A study of 100 consecutive cases.
Sigrud Gunderson, M.D., LaCrosse, Wis.

BANQUET

6:30 o'clock—Mankato Country Club

Toastmaster—Waltman Walters, M.D., President.

Addresses by:

W. J. Mayo, M.D.

S. H. Boyer, M.D., President of the Minnesota State Medical Association.

E. S. Judd, M.D., President-elect of the American Medical Association.

W. A. Rohlf, M.D., President of the Iowa State Medical Association.

ANNUAL MEETING AT DULUTH

The annual meeting of the State Association held at Duluth was particularly well attended, there being 641 registrants as compared with 500 at the meeting three years ago at Duluth. The participation by guests from other parts of the country and from abroad afforded added interest to the program.

The scientific program was diversified but in the main interesting. The poor acoustics of the ballroom of the Hotel Duluth detracted considerably from the enjoyment of the program. Few physicians know how to speak well, and on the other hand, few are at ease with the microphone of a loud speaker. They can learn, however. It was also unfortunate that the county delegates had to miss so much of the scientific program, through attendance at the two meetings of the House of Delegates. This conflict should and doubtless will be avoided in the future. A dozen or more members had the unfortunate experience of having their pocketbooks stolen from their rooms in the Hotel Duluth while they peacefully slept. Travelers' checks are not much bother and will doubtless be more popular with certain members attending state meeings in the future.

Advantage was taken of the opportunity to obtain an expression of opinion regarding the value of Dr. Hanson's thymic extract in the treatment of cancer. Some twenty-five Minnesota physicians met and each gave his experience. No cures were reported. For the most part advanced cases of carcinoma in which surgery, *x*-ray or radium had failed constituted the majority of those reported. In a few instances the physicians thought there was a definite reduction in the size of metastatic tumor growths. Some reported the definite relief of pain. Dr. Hanson referred to experiments now being conducted to test the true value of his extract.

Our meetings in Duluth are always popular. Not too far to reach by motor, the scenic grandeur of Minnesota's port never fails repeatedly to thrill the visitor. And there is always evident a feeling of real cordiality on the part of the Duluth members of the Association.

The minutes of the meeting will eventually appear in the journal. Suffice it to say that our next meeting will be in Minneapolis and the following officers were duly elected:

President—Dr. L. Sogge, Windom.

First Vice President—Dr. W. H. Condit, Minneapolis.

Second Vice President—Dr. O. W. Parker, Ely.

Secretary—Dr. E. A. Meyerding, Saint Paul.

Treasurer—Dr. A. G. Schulze, Saint Paul.

Councilor Second District—Dr. W. A. Piper, Mountain Lake.

Councilor Fourth District—Dr. J. S. Holbrook, Mankato.

Councilor Sixth District—Dr. N. O. Pearce, Minneapolis.

Councilor Eighth District—Dr. O. J. Hagen, Moorhead.

A. M. A. Delegates—Dr. H. M. Johnson, Dawson; alternate, Dr. B. S. Adams Hibbing. Dr. W. F.

Braasch, Rochester; alternate, Dr. W. L. Burnap, Fergus Falls.

WABASHA COUNTY MEDICAL SOCIETY

The sixty-second annual meeting of the Wabasha County Medical Society was held at Wabasha Thursday, July 10, Doctor Russell H. Frost presiding.

There were twenty-four in attendance, including members, guests and accompanying doctors' wives.

At the business session in the forenoon, various matters were discussed, committee reports received, and one new member was elected, Dr. Clifford N. Rudie of Mazeppa. Officers were elected for the coming year as follows: President, Dr. E. C. Bayley, Lake City; vice president, Dr. W. B. Stryker, Plainview; secretary-treasurer, Dr. W. F. Wilson, Lake City. Delegate to state association, Dr. W. H. Replogle, Wabasha; alternate, Dr. D. P. Dempsey, Kellogg. Censor for three years, Dr. J. A. Slocumb, Plainview, to serve with Drs. Cochrane of Lake City and Bond of Wabasha. It was voted to hold the next annual meeting at Lake City.

Dinner and other entertainment was afforded through the courtesy of the members residing at Wabasha and Kellogg.

In the afternoon, the following program was presented:

President's Address—"Some Newer Aspects of the Tuberculosis Problem," Dr. Russell H. Frost, Superintendent Buena Vista Sanatorium, Wabasha.

"Undulant Fever with Report of a Case," Dr. E. Cóvell Bayley, Lake City.

"Recent Developments of Surgery," Dr. Waltman Walters, Mayo Clinic, Rochester.

"Surgical Problems of the Gall-Tract," Dr. Joseph S. Collins, Wabasha.

"Relation of the Medical Profession to the Public," Mr. F. Manley Brist, Attorney for the State Board of Medical Examiners, Saint Paul.

Other speakers were Dr. M. S. Henderson of Rochester, Councilor for this district, and Prof. Felix von Mikulicz of the Frauenklinik, University of Berlin, who came as a guest with the surgeons from the Mayo Clinic. It was esteemed quite a privilege to hear this distinguished German professor talk on the methods of treating cancer at his clinic.

All the papers were well received and elicited general discussion.

A rising vote of thanks was tendered to the outside speakers and all those who had part in the entertainment of the society.

W. F. Wilson, M.D., *Secretary.*

SCOTT-CARVER COUNTY MEDICAL SOCIETY

A meeting of the Scott-Carver County Medical Society was held at Watertown, Minnesota, July 8, 1930.

Dr. C. D. Harrington of Minneapolis addressed the society on the "X-ray Diagnosis of Gastrointestinal and Gallbladder Lesions."

Dr. A. E. Benjamin discussed the "Lesions of the Gastrointestinal Tract and Gallbladder and Their Surgical Treatment." Upon invitation from Dr. F. H. Buck it was decided to hold the next meeting at Dr. Buck's cottage at Prior Lake in August.

B. H. Simons, Secretary.

MISCELLANEOUS

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

UNLICENSED PRACTITIONER OF MEDICINE FINED $500

State *vs.* Ziegler

The defendant, Fred Ziegler, of Elmore, Minnesota, was arrested June 18, 1930, for practicing medicine without a license at Springfield, Minnesota. The defendant, a man sixty-one years of age, has been engaged in bleeding and cupping for the past twenty-six years in Faribault County. He has no medical education except a correspondence course in Chiropractic. He claims to have a "Degree of Doctor of Naturopathy." On Friday, July 11, Ziegler entered a plea of guilty before the Hon. A. B. Gislason, Judge of the District Court at New Ulm, Minnesota, and was fined $500. Ziegler paid the fine. The defendant was warned that he would have to refrain from practicing in the future or he would be dealt with more severely. The imposing of substantial fines as was imposed by Judge Gislason in this case will go a long way in eradicating quacks, fakers and unlicensed practitioners. The Court in no uncertain terms informed the defendant that such practices would not be tolerated in this State. Judge Gislason is to be commended not only by the medical profession, but by the public, for his firm stand on these matters. The matter was handled by Mr. Brist on behalf of the State Board of Medical Examiners and splendid coöperation was received from T. O. Streissuth, County Attorney, and Sheriff J. J. Reitter of Brown County.

DIGESTIVE ENZYMES FOR ORAL ADMINISTRATION OMITTED FROM N. N. R.

The Council on Pharmacy and Chemistry reports that in consideration of the replies to a questionnaire sent out in 1925 it was decided at that time to continue the acceptance of gastric ferment preparations, including those intended for internal administration, to await confirmatory evidence in favor of their use. No acceptable evidence showing the value of gastric enzymes when administered orally having become available, the Council has omitted all digestive enzyme preparations save those recommended for use outside the body for the digestion of food previous to administration and locally for the softening of dead tissues or the solution of false membranes. The following are the products which have been omitted: Elixir of Enzymes (Armour & Co.); Essence of Pepsine-Fairchild, Gastron, Holadin and Diazyme Glycerole (Fairchild Bros. & Foster); and Panase (Frederick Stearns & Co.) (Jour. A. M. A., June 14, 1930, p. 1919.)

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

OBSERVATIONS ON THE ETIOLOGICAL CORRESPONDENCE BETWEEN ANGINAL PAIN AND CARDIAC INFARCTION: Carey F. Coombs, From the University Centre of Cardiac Research, Bristol (Quarterly Jour. of Med., April, 1930, p. 233). The histories given by a series of patients presenting themselves because of precordial pain were scrutinized. These were divided into two groups, the first group of 86 cases consisting of cases in which cardiac pain, persistent in character, not necessarily excited by effort, was followed by evidence of gross injury to the wall of the heart; the second group, consisting of 201 cases, in which pain was excited by effort, relieved by its cessation, and not followed by structural sequelæ. The age and sex incidence of the two groups corresponded closely with one another.

The angina of effort occurs principally in association with cardiac syphilis, high arterial tension, and senile degeneration of the heart. Cardiac infarction occurred in the second and third of these groups; namely, hypertension and senile degeneration, but occurred rarely in cardiac syphilis. Both syndromes, *i.e.,* the angina of effort and cardiac infarction, are rare in the other infective and toxic diseases of the heart. The occurrence of cardiac pain in pernicious anemia is referred to. In the author's own series of 36 cases, substernal pain of the cardiac type was mentioned eight times, a much higher incidence than Willius and Giffin encountered in their cases.

There are three structures concerned in the supply of arterial blood to the wall of the heart: the first part of the aorta, the aortic semilunar valves, and the coronary arteries. For proper function the aorta must be elastic, the semilunar valves competent, and the coronary arteries pervious and distensible. Competency of the aortic valves is the least essential requisite of this apparatus for supplying blood to the cardiac wall. The author inclines to believe there is no real rivalry between the aortic and coronary hypothesis of angina. In some cases, it is the fault of one, in others the fault of the other part, and again both parts may be so damaged as to be inefficient. The author believes coronary arteries to be the principal offenders in provoking angina. Rigidity of the coronary arteries as well as stenosis has an important bearing on the efficiency of the artery. Cardiac infarction is rare in cardiac syphilis, because it does not alter the arterial linings in such a way as to prepare them for the formation of thrombi, these vessels being attacked by this condition only at their orifices.

It is concluded that pain of an anginal kind is produced by all the diseases which fail to forward oxygenated blood to the cardiac muscle.

PHENYLETHYLHYDANTOIN IN THE TREATMENT OF SYDENHAM'S CHOREA: Hartzell H. Ray, M.D., and John S. Cunningham, M.D., Rochester, N. Y. (Amer. Jour. of Dis. of Children, Vol. 39, No. 6, June, 1930). Phenylethylhydantoin was introduced under the name "nirvanol" in 1916 as a sedative. The frequent occurrence of severe symptoms such as rash or fever led many authors to warn against its use. In 1919, Roeder recommended phenylethylhydantoin in the treatment for chorea minor.

The dose for younger children was 0.3 Gm. (5 grains) per day; for the older children, 0.6 Gm. (10 grains); the drug was given for from seven to nine days.

Observations suggest the following conclusions: Treatment with phenylethylhydantoin greatly shortens the course of Sydenham's chorea. This effect is more obvious in the more severe cases. The recurrence of chorea is no more frequent after the administration of phenylethylhydantoin than after other forms of treatment. The beneficial results did not always seem to depend on the development of fever or rash. On the basis of this small series of cases, no claim can be made that all patients with chorea will respond to the treatment. The relatively poor response in mild cases strongly suggests that many will not.

Phenylethylhydantoin proved more effective than other drugs in the treatment of chorea. In the present comparative study, the mean duration of chorea from the beginning of treatment was thirty-one days when phenylethylhydantoin was used, and one hundred and fifteen days when other drugs were used.

Mild chorea is not so rapidly cured as is the severe

form. Although "nirvanol sickness" may cause considerable temporary discomfort, we have observed no permanent harmful effects from the drug.

On account of the possible danger of injury to the bone-marrow, it is desirable that frequent blood counts be made in cases in which patients with chorea are treated by phenylethylhydantoin. The administration of the drug should not be continued over periods longer than ten days, or after the appearance of the eruption.

R. N. Andrews, M.D.

ASTHMA IN CHILDREN: M. Murray Peshkin, M.D., New York (Amer. Jour. of Dis. of Child., April, 1930, Vol. XXXIX, No. 4). With the introduction of protein skin tests in the past decade, the entire subject of asthma from the standpoint of etiology and treatment has undergone radical revision.

It has become evident that to fix the causative factor in asthma there is required not only a complete series of protein skin tests accurately performed and properly interpreted, but a carefully taken history, a physical examination, including roentgenoscopy of the chest, tuberculin skin and various laboratory tests, and a careful study of the patient over a considerable period.

A practical method of classification of asthma along etiologic lines is now possible. In this new classification there are three main groups, which include all types of asthma: (1) protein sensitive asthma; (2) protein non-sensitive asthma, and (3) para-asthma (these cases are directly caused by an enlarged thymus or enlarged bronchial lymph nodes or both, and also by any pathologic condition inducing tracheobronchial stenosis).

It must be conceded that at least between 10 and 60 per cent of the patients who have received modern treatment continue to have asthma.

Twenty-five children (twenty-two children sensitive and three non-sensitive to protein) were treated by a change of environment. In spite of the fact that the inhalant and the dietetic restrictions were kept less rigid than at home, twenty-three children, or 92 per cent, were markedly improved or entirely relieved of asthma. Seventeen of these twenty-five children have been returned to their homes for periods varying from 6 months to 5 years or an average of 2 years per patient. Thirteen of these seventeen children, or 76 per cent, are not greatly improved or relieved from asthma. In some of these children, appropriate treatment after change of environment was successful, whereas it has failed before.

Until newer methods of treatment are advanced which will successfully control or free this group of children from asthma, the establishment of a "home" where a child with chronic refractory asthma can be kept for at least six months, is regarded as a humane, urgent and economic necessity, as well as a therapeutic measure of definite value.

HOT SPRINGS, SOUTH DAKOTA

ATROPHIC AND VASOMOTOR RHINITIS Simon L. Ruskin, New York (Arch. of Otolaryng., Vol. II, No. 6, June, 1930, p. 689). In a series of cases in which I gave injections into the sphenopalatine ganglion for relief from the painful syndrome of neuralgia of the nasal ganglion, following the injection I observed nasal congestion that lasted for a period of time varying from a few days to two or three months.

It also occurred to me that in the more advanced state of so-called atrophic rhinitis there may be a profound and continued influence on the vasoconstrictor nerves, inducing a state similar to that of Raynaud's disease in the extremities. I selected a typical case of atrophic rhinitis. I made injections into both nasal ganglions by the posterior palatine route. Following the injection there was a gradual diminution of nasal secretion with a lessening in the amount of crusting. Subsequently, the tissues began to take on a pinkish color and to assume a fuller appearance. After three weeks, it was apparent that the left side was improving more rapidly than the right. I therefore again gave injections into the right nasal ganglion. Within a few days after the injection the right side showed distinct improvement. At present, there is hardly any crusting on the left and only a small amount of crusting on the right. The foul odor has practically disappeared. The patient formerly suffered from an associated dry pharyngitis. At present she is practically free from any complaint referable to the pharynx.

I am led to suggest that atrophic rhinitis, so-called ozena, when not due to sinusitis is a disease caused by the abnormal sensitiveness of the vasoconstrictor nerves resulting in a continuous or intermittent spasm of the smaller arteries and arterioles.

Just as interesting as the influence of freeing the atrophic nasal membrane from the vasoconstrictor action is that induced by section of the vasodilators in so-called vasomotor rhinitis. In the tonic or intermittent overaction of the vasodilators there is a boggy, bluish, pale membrane filling the nasal fossæ and seeped in thin serous discharge. This appearance is common in allergic conditions and is variously diagnosed. When it is associated with specific sensitivity as demonstrated by skin tests, it is classed as hayfever or protein sensitivity. When it is not associated with a specific skin reaction, it is frequently called vasomotor rhinitis. The observations on both nasal mem-

branes are the same, and the interesting thing is that both react alike to blocking of the vasodilators. In both instances the nose becomes dry and the nasal passages clear.

In the allergic states both nasal ganglions must be blocked simultaneously. Following the injection of alcohol-phenol, the cheeks become somewhat puffy for a few days as after the extraction of a tooth. The dryness of the nose becomes apparent in about twelve hours, at times within one or two hours.

CONCLUSIONS

Atrophic rhinitis when not due to sinusitis is a disease caused by the abnormal sensitiveness of the vasoconstrictor nerves which results in a continuous or intermittent spasm of the smaller arteries and arterioles.

Vasomotor rhinitis is a disease similarly caused by the abnormal sensitiveness of the vasodilator nerves which results in a continuous or intermittent relaxation of the smaller arteries and arterioles.

Both the vasodilators and the vasoconstrictors of the nasal mucous membrane can be cut or blocked at the nasal ganglion.

ARTHUR C. DEAN, M.D., F.A.C.S.

SUB-MAXILLARY FOSSA APPROACH TO DEEP PUS IN THE NECK: Harris P. Mosher (Trans. of the Amer. Acad. of Ophthalmology and Otolaryngology, 1929. Page 19). The pharyngo-maxillary fossa most frequently becomes infected by extension from the following structures: first, the tonsils; second, the glands just anterior to the second cervical vertebra and its fascia, which drain the nose and pharynx and are the glands that suppurate in the retropharyngeal abscess of infants; third, the parotid or the tip of the mastoid. Pus thus formed may kill the patient by rupturing into the larynx or trachea, or more slowly by causing a thrombosis of the internal jugular vein with subsequent septicemia.

The cervical fasciæ are prolongations of the carotid sheath. This makes the carotid sheath a core of all the soft structures of the neck. By following it pus may reach the base of the skull above or the chest below, so it must be followed in ordered to locate hidden abscesses as this is the natural highway for pus.

There are three fossæ in this region—two actual, the sub-maxillary and the parotid, and one potential, the pharyngo-maxillary. The last may be regarded as a cone, with the base attached to the skull around the jugular foramen and the apex at the hyoid bone. The carotid sheath emerges from the apex of the cone and for all practical purposes, continues the fossa into the thorax.

The inner boundary of the fossa is the superior constrictor muscle with the tonsil attached. The outer boundary below, is the internal pterygoid muscle lining the inner surface of the ascending ramus of the lower jaw; above it is the parotid gland, which at this point is not covered. Posteriorly are the prevertebral muscles and fascia. The fossa is divided into unequal parts by the styloid process and the muscles arising from it. These are in front of the great vessels and protect them.

In tying the external carotid artery, a large T-shaped incision is made beginning just below the angle of the jaw and following the edge of the sterno-cleido-mastoid down for about 2 inches. If the neck is thick and deep a rectangular flap is turned down. The object is then to find the tip of the great horn of the hyoid. The external carotid will then be found lying just outside the tip.

The sub-maxillary fossa approach commands the side and base of the tongue, the floor of the mouth, and the neck from the base of the skull to the clavicle. A generous T-shaped incision is made and the sub-maxillary gland is exposed and turned up. The facial vein runs across the middle of the field so it must be tied and cut. The carotid sheath lies opposite the tip of the great horn of the hyoid. The sheath is then followed upward and downward. Upward the finger enters the pharyngo-maxillary fossa and passes to the outside of the tonsil. Continuing upward the styloid process is felt and lateral to this, the base of the skull.

In dealing with pus at the base of the tongue or in the floor of the mouth, an incision is made at the base of the sub-maxillary fossa. This can be carried forward or backward as indicated.

L. G. FLANAGAN.

BRONCHIECTASIS, AN UNAPPRECIATED CAUSE OF CHRONIC BRONCHITIS: Alton Ochsner (Jour. A. M. A., Vol. 93, p. 188, July 20, 1929). This is an article about bronchiectasis and gives a new way to introduce iodized oil into the lungs. The author calls it the "passive technic."

1. Use antiseptic mouth wash.
2. Paint anterior surface anterior tonsil pillars with 10 per cent cocain solution until swallowing reflex is lost.
3. Three c.c. 3 per cent procain hydrochloride solution is taken into mouth. Tip head backward, protrude the tongue, lean slightly to side that it is desired to fill, breathe.
4. Paint the anterior pillars again as in procedure 2.
5. Place patient behind fluoroscopic screen—swallow 10 c.c. iodized oil—assume position and tactics as in procedure 3. Watch oil flow into lung.
6. Expectorate saliva and inhale a second 10 c.c. of the oil.

LEO G. RIGLER,
UNIVERSITY HOSPITAL, MINNEAPOLIS

A. U. DESJARDINS,
MAYO CLINIC, ROCHESTER

STUDY OF ROENTGEN THERAPY IN MENTAL AND NERVOUS DISEASES OF CHILDHOOD: W. von Wieser (Strahlentherapie, Bd. 31, 1928, 147-163). This study of the effect of roentgen therapy in mental and nervous diseases of childhood was begun in 1923 as a result of the observation that the irritability of children can be improved by radiation of the brain. It was then observed that other symptoms besides irritability were influenced by radiation. The symptoms which can be influenced are classified at length under

(A) Mental disturbances, which include disturbances of the senses, memory, coördination, attentiveness, vanity, feelings, moods, affections, disturbances of the primitive motions and actions, temperament, character, and

(B) Bodily disturbances, including the various abnormalities of development, deficiencies of speech, stuttering, gross motor defects, as muscular weakness and lameness, convulsive attacks, endocrine disturbances, etc.

While at first the attempt was only to treat the symptoms, cases were later treated systematically according to the diagnosis, as the favorable effect on many symptoms was gradually made manifest.

The indications based on Ziehen's classification include:

(A) Psychoses with defects of intelligence under which are included:
  I. Congenital psychoses, as mongolism (see below, abstract of special article dealing with this condition), dysgenital imbecility and microcephalic imbecility.
  II. Acquired psychoses (dementia), including various forms of dementia epileptica, and dementia on the basis of encephalitis, meningitis, etc.

(B) Psychoses without defects of intelligence, including various forms of noetic psychoses, periodic psychoses and psychotic constitutions.

(C) Bodily disturbances with normal mentality, under which are included disturbances of growth, as chondrodystrophy and dwarfism.

It is pointed out that mental improvements are usually secondary to bodily improvements and that this is one explanation of the mental effects obtained as a result of radiation, which first brings about an improvement in growth and in the physical condition. The effects on other symptoms are due to the well known beneficial effects of radiation on inflammations and scars, which are the underlying pathology in some of these conditions.

Radiation was directed primarily to both temporal regions. Because of the associated endocrine disturbances in most of these cases, the thyroid, thymus and genitals were soon also treated and later also the cervical, thoracic and lumbar spinal cord, adrenals and tonsils, because symptoms due to abnormalities of these parts were often present.

Tuberculosis is often a complication. Radiation is then usually not indicated until the tuberculosis has improved, when it may be unnecessary because of the coincident improvement in the neurological and mental condition. Treatment is not indicated in high grade hydrocephalus when active inflammation is present, in cases of marked microcephaly when the sutures are completely closed, and in all cases with marked elongation of the dorsum sellæ.

Experience has led to a marked reduction in the doses at first given and in certain cases to an increase in the intervals. The head is now radiated through five different areas, one area at a time. According to the nature of the cases, treatment of combinations of regions is indicated, as brain, spinal cord, and the glands of internal secretion.

The most difficult and important problem is the determination of the correct dose. Complete clinical examination, taking into account all associated conditions, is a necessary preliminary. Basal metabolism, capillary microscopy and especially the ferment reaction of Abderhalden, are of great value in dosage estimation. The most important thing to realize is that doses of 1 to 2%, measured at the lesion, given once a week, which for other purposes are considered small doses, may under certain conditions be 5 or 10 times as large as should be given.

EDWARD SCHONS, M.D.

FURTHER EXPERIENCES WITH ROENTGEN THERAPY IN PSYCHIATRIC AND NEUROLOGICAL DISEASES. I. Mongolism: W. von Wieser (Strahlentherapie, Bd. 32, 1929, 215-292). The writer has made a considerable study of the effects of roentgen treatment in various forms of weak-mindedness in children. This paper is his first publication on a specific disease, having chosen mongolism as his first subject for 6 reasons: (1) It is the easiest to treat; (2) with the exception of myxedema and cretinism, it is the best known; (3) it is the most exactly defined; (4) its course without treatment is at least known to some extent; (5) likewise its course under medical treatment; (6) the cases are so similar that comparison between treated and untreated cases is possible.

The first part of the paper deals with a description of the disease and its principal symptoms, pathological and anatomic findings, prognosis and results with usual treatment. The paper is based on his experiences in the examination and treatment of forty-six cases, varying from 6 months to 18½ years of age. Twenty-eight of the cases received deep *x*-ray therapy. Of the untreated cases it was possible to follow 6 cases

as controls. The time of observation of the treated cases ranged from 8 months to 3⅔ years, the average period of observation of the treated cases being 17 months, of the untreated 26 months.

The first physical characteristic proven to be influenced by roentgen treatment is the growth in height and weight. The effect of *x*-ray treatment on the rate of growth is discussed very elaborately and compared with the untreated control cases by numerous charts and curves. The studies show that the effect of *x*-ray treatment on the rate of growth in mongolism is almost as marked as the effect of thyroid treatment in cretinism and myxedema. Comparison of treatment of mongolism by organotherapy is not possible, as there are no cases reported in the literature. It is emphasized particularly that the maximum or most favorable effect on the growth is directly dependent on the correct dosage, either too small or too large a dose being detrimental.

The effects on the many features of these cases are discussed in detail and compared with the control cases, the treated cases showing a marked advantage in the improvement of all symptoms over those which were not treated. Less reliance is placed upon comparison of the psychic symptoms before and after treatment with those of the control cases than on the physical characteristics, comparison here being more difficult. A definite improvement in mentality, speech, and progress in school work is, however, shown. Practically all of the symptoms showed the greatest improvement at the ages from 4 to 7. This is attributed entirely to the dosage having been approximately correct for this age period.

The present treatment consists of irradiation of the head, using five areas, 6 × 8 cm., in size, at a 30 cm. target-skin distance, voltage 180 to 200 K. V. P., ½ mm. zinc plus 1 mm. aluminum, 5 to 10 per cent of the erythema dose per area, one to 2 areas a week at intervals of three to four days; in younger children often only one area in two weeks, in extreme cases only one area in four weeks. Usually the five areas were treated successively twice, followed by intervals of at first four and later six, eight or ten weeks. In the early cases the doses were greater, often two areas receiving each 25 to 30 per cent. Both areas were again treated in four weeks, with intervals of from six to eight weeks and over after the third series. The areas were so arranged that the lower half of the middle fossa of the skull and the nasal sinuses were treated. In children under three radiation of the entire body with 2 per cent of an erythema dose at 2 meters, given at intervals of four weeks, were frequently sufficient. Radiation of the thyroid, thymus and genitals with small doses was done at first but has now been given up, as the same results can be obtained more certainly with radiation of the skull. The dose is gauged according to the severity of the case and the age of the patient. Organotherapy was combined in the earlier cases but has been dropped, as its effects were found to be subordinate to those from radiation and such treatment was ineffective in taking the place of radiation.

Edward Schons, M.D.

CANCER DEATH RATES IN VARIOUS CITIES

A comparison of the cancer death rates in various cities throughout the United States indicates that the increasing incidence of the disease is not limited to any one section of the country. The accompanying chart shows the death rates from cancer in Boston, New York, Philadelphia, Chicago, St. Louis, and San Francisco, as computed by the United States Census Bureau. Each of these cities, it will be seen, had a higher rate in 1927 than in 1920. In New York, for instance, the cancer death rate per 100,000 of estimated population was 104.1 in 1920, and 139.0 in 1927, an increase of 35 points. In Boston, although the increase was not so great, the rate for 1927 was the highest among the six cities; that is, in 1920, the cancer death rate there was 116.9 per 100,000, and in 1927 it was 139.5. On the Pacific coast, San Francisco had a cancer death rate of 130.9 per 100,000 in 1920, and of 135.4 in 1927, while St. Louis, in the Middle West, had a rate of only 99.7 in 1920 and of 119.7 in 1927. In Chicago, the cancer death rate in 1920 was 103.6 and in 1927 it was 120.4. In Philadelphia, which has the lowest rates of the six cities, the increase was from 93.5 in 1920 to 112.0 in 1927. It must be remembered, however, in making a comparison of these different rates, that the recorded prevalence of cancer depends largely on the ability of the physician in diagnosing the disease and on the accuracy of death certificates. Increased efficiency and accuracy are probably responsible for some part at least of the rise in the recorded death rates. It must also be remembered that the death rates in the cities are higher than those in the rural districts because many patients are attracted from the country to the hospitals in the cities, and their deaths are often included in the city records. The importance of variations in correctness of diagnosis is shown by the fact that routine autopsies of patients in institutions for the aged or in large city hospitals reveal about 30 per cent of undiagnosed cases of cancer.

These statistics, based on adjusted rates, have been compiled from the reports of the United States Census Bureau, by the American Society for the Control of Cancer.—*Health News*, July 7, 1930.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

REPORT ON FIFTH INTERNATIONAL CONGRESS OF MILITARY MEDICINE AND PHARMACY, London, England, May, 1929. By Commander William Seaman Bainbridge, M.C.-F., United States Naval Reserve. 154 pages. Illus. Menasha, Wis., The Collegiate Press, 1930.

SURGICAL AND MEDICAL GYNECOLOGICAL TECHNIC. Thomas H. Cherry, M.D., F.A.C.S., Professor of Gynecology, New York Post-Graduate School and Hospital. Cloth. Price, $8.00. 678 pages, with 558 illustrations. Philadelphia: F. A. Davis Company, 1929.

The purpose of the author is best presented in his own words: "I have attempted to present in this work, which in all teaching is of great value, a single method of therapy, based upon anatomy and pathology and to give sufficient illustrations to make this logical and comprehensive; in the surgical descriptions to present a sufficient number of illustrated steps, that a gap in sequence would not exist, so that one could readily follow the operation to its completion."

The book is neither a text nor an encyclopedia. The method of treatment described for each condition is that one which the author has used with results satisfactory to himself. The reader is thus spared elaborate discussions of a variety of methods. The absence of physiology, symptomatology and of diagnosis emphasizes the single purpose of the volume.

The text is concise, but is supplemented so aptly by the author's own pen and ink engravings that the reader will be able to follow the steps of operative procedures with less difficulty than usual. These drawings are a feature of the book which the author refers to rather apologetically, but which the reader will find uniformly and singularly clarifying.

The book is divided into two sections, one on surgical, the other on medical technic. The first section occupies 520 pages.

In the surgical section the chapter headings will indicate the general arrangement of material, viz., Hernias, Plastics, Fistulas and Bladder Operations, Uterine Operations, Adnexal Operations, etc. There are also chapters on Suture and Drainage Material, on Anesthesia, with a considerable discussion of Spinal Anesthesia, and on the Care of Operative Gynecological Patients.

In the Medical Section there is a detailed description of the use of diathermy in pelvic infections of gonorrheal origin. In the gas inflation test for tubal patency he uses only a glass syringe, a uterine canula and a pressure gage—an astonishingly simple procedure compared, for example, to that followed by Rubin.

E. C. HARTLEY, M.D.

CLINICAL MEDICINE: Paul H. Ringer, 3rd Revised edition. $3.00. Philadelphia: F. A. Davis Co.

A comprehensive volume, practical, well presented, with material that is up to date.

The author states that the book is bereft of dogmatic material, and may be amplified to suit individual teachers' needs. I find this to be very true, and for this reason an excellent volume for outline material.

The author, in my opinion, has carefully considered the needs of the student nurse, and compiled his material accordingly. Particular attention has been given to pathology.

The volume does not give as much detail as the average clinical volume for teaching. The objection, however, to most clinical books for teaching has been too much detail.

INEZ PEYTON.

TUBERCULOSIS AMONG CHILDREN: J. Arthur Myers, Ph.D., M.D., F.A.C.P., with chapters by C. A. Stewart, M.D., Ph.D., and Paul W. Giessler, M.D., Minneapolis. 208 pages. Illus. Price, $3.50. 1930. Charles C. Thomas, Publisher, Springfield (Ill.) and Baltimore.

Tuberculosis in children and its relation to tuberculosis in adults has received intensive study during the past decade. The author has reviewed the vast literature fully and has combined it with his personal experience in private practice and as Medical Director of the Lymanhurst School for tuberculous children, in the preparation of this book. The result is a compact summary of our present day knowledge of tuberculosis in children as generally accepted by foremost teachers and clinicians.

The writer emphasizes the point that tuberculosis is a family disease which spreads largely by direct contact. Bovine infection is still a factor. The varying incidence of tuberculous infection in different parts of the country is pointed out, showing that tuberculous infection no longer may be considered universal. Tuberculous infection in infancy does not have the grave prognosis it once had. The importance of the tuberculin test at all ages is stressed, the Mantoux or intradermal being considered preferable to the von Pirquet. As to the general value of the skin test, the author states, "Tuberculin tests applied to all children of a community is the best method of approaching the tuberculosis problem. Among the positive reactors will be found children with the disease and among their adult associates will be found open cases of tuberculosis previously unrecognized."

The subject of "The Childhood Type of Pulmonary Tuberculosis" is treated fully, as it is found in infancy and later childhood. The necessity for routine x-ray films in all children reacting positively to tuberculin is emphasized. Family history is likewise important—

symptoms and physical signs may be entirely absent. The study of tuberculosis in children is of great value because such a large number of the 'teen age group developing the adult type of pulmonary tuberculosis shows x-ray evidence of a childhood type of pulmonary tuberculosis.

Well written chapters are contributed by Dr. C. A. Stewart on "Tuberculous Meningitis" and "Chronic Non-Tuberculous Basal Pulmonary Diseases in Childhood," and by Dr. Paul W. Giessler on "Tuberculosis of the Bones and Joints."

This brief volume should be of value to the medical student, general practitioner, pediatrician and to all those interested in tuberculosis in children. Each chapter contains a short summary and a very complete bibliography which is valuable for reference work.

P. M. MATTILL, M.D.

NEW AND NON-OFFICIAL REMEDIES, 1930. Cloth. Price, $1.50. Pp. 481; xlviii. Chicago: American Medical Association, 1930.

The present edition contains all of the features that have in the past made New and Non-official Remedies such a reliable and efficient guide to the physician who wishes to inform himself on the newer medicinal preparations: logical classification of preparations, with authoritative articles on each class; complete and carefully written descriptions of preparations; elaborate indexes; and a useful cumulative list of references to the literature on articles not accepted by the Council. Among the more important revisions that appear in this edition are those of the general articles, Barbital and Barbital Compounds, Digestive Enzymes, Cod Liver Oil and Cod Liver Oil Preparations, Ovary, Pituitary Gland, Radium and Radium Salts, and Serums and Vaccines. Among the new preparations descriptions of which appear for the first time in this edition are: Bismarsen, which is sulpharsphenamine bismuth; Dial-Ciba, which is diacetylbarbituric acid; Calcium Gluconate-Sandoz, a more palatable and less irritating preparation of calcium; Atoquinol-Ciba, a cinchophen derivative; Pitocin and Pitressin, solutions respectively of the oxytocic and pressor principles of the pituitary gland; Viosterol (the Council name for irradiated ergosterol) in the forms of Viosterol in Oil 100 D, which is irradiated ergosterol dissolved in vegetable oil; and Cod Liver Oil with Viosterol 5 D, which is cod liver oil with its vitamin D potency enhanced by addition of viosterol. While these new preparations (with the possible exception of Viosterol) do not constitute major additions to the physician's armamentarium, each one gives promise of relative usefulness, and the physician who desires to keep abreast with the progress of therapeutics will familiarize himself with them as well as with the many other new preparations described in this valuable book.

ANNUAL REPRINT OF THE REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR 1929. With Comments that have appeared in The Journal. Cloth. Price $1. Pp. 81. Chicago: American Medical Association, 1930.

This is the volume in which the Council annually collects the reports on articles found unacceptable during the year. This edition contains also several interesting preliminary reports on preparations which show promise but for which the evidence is not yet sufficient to justify acceptance by the Council. Reports are given on the following products rejected by the Council: Anayodin, claimed to be iodoxyquinolinolin sulphonic acid (chiniofon) but marketed under a non-informing name without adequate statement of composition and with unwarranted therapeutic claims; Antiustio, an unscientific mixture marketed under a non-descriptive name with unwarranted therapeutic claims; Kerasol and Keraphen, unoriginal products marketed under non-informing names; Sodiphene, an unoriginal alkaline phenol preparation marketed under a proprietary name with unwarranted therapeutic claims; Borocaine, procaine borate under a proprietary name; Quicamphol (Transpulmin), a quinine preparation for intramuscular injection in the treatment of lobar pneumonia; Toxogon, a preparation of inadequately declared composition marketed under a therapeutically suggestive name; Intramuscular Iron Arsenic Comp. (No. 201) and (Intravenous) Iron Cacod. and Glycerophosphate (No. 202), two irrational and unscientific mixtures exploited with emphasis on the numbers. Other rejected products are: Ovoferrin, Tamerici Salts, Elixir Kacyan-McNeil, and Tablets Kacyan-McNeil. An authoritative article on serum disease and serum accidents by MacKenzie and Hanger is of considerable interest and timely importance.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

WANTED—Assistant director of one hundred bed county tuberculosis sanatorium. Address MINNESOTA MEDICINE, D-91.

WANTED—Locum tenens work for August and September. Three years' hospital experience since graduation. Twin Cities references furnished. Address D-93, care MINNESOTA MEDICINE.

POSITION WANTED—X-ray technician; four years' experience in large hospital, desires position in clinic, hospital or doctor's office. Available immediately. Address D-92, care MINNESOTA MEDICINE.

MINNESOTA MEDICINE

Journal of the Minnesota State Medical Association. Southern Minnesota Medical Association, Northern Minnesota Medical Association, Minnesota Academy of Medicine and Minneapolis Surgical Society.

VOL. XIII SEPTEMBER, 1930 No. 9

PRESIDENT'S ADDRESS*

S. H. Boyer, M.D.
Duluth, Minnesota

A GENERATION ago the muck-rakers were attacking corporate business. Their destructive criticism succeeded in working a great deal of serious inconvenience to the business methods of that time, but the ultimate result was to popularize still greater business combinations and the muck-raker was thereby out of a job. He is an ubiquitous fellow, however, and always trying to smash something. He is destructive, never constructive. Latterly he has been chiefly concerned with the medical profession. For years past he has been picking it to pieces and tearing it to tatters. Were it not made of such substantial fabric it would have met its Waterloo long ere this and the field of healing would have been abandoned to fakers and quacks.

Nevertheless there are faults and flaws in medicine just as in everything else. As a profession we must be grateful to him who points them out to us, and likewise glad to enlist assistance in correcting whatever evils or defects there may exist. It so happens that the science of medicine in seeking the cure for disease first tries to learn the causes thereof. This approach to the problem offers always the best hope of correct solution. Before proceeding farther let it be clearly understood that the economico-social problems of medicine are not isolated. They are not the property of medicine alone. They are not due to any failure of duty or responsibility on the part of the profession and they are inextricably interwoven with the same order of problems of all other social and industrial groups. The solution of our problems can come only with the solution of these related problems of all groups, for the economico-social problems of medicine are in truth the problems of society itself.

Among the charges brought against us are those of uneven distribution of service, inequality of service and excessive fees, the latter more especially in relation to the patient's income. Reference is made to the group whose earnings do not exceed $2,500.00 per annum and does not consider the indigent.

Not long since, it was pointed out in an article dealing seriously with the uneven distribution of medical service that in New York City, just around the corner from a great medical center, there was discovered a number of untreated cases of diphtheria. Wonder was expressed that, though living almost in the shadow of a center where medical skill of the highest order obtained, still these people were neglected. The article went on to blame the medical profession for failing to reach and treat these cases. Uneven medical distribution was given as the reason for the failure. Paralleling this type of complaint is the widely heralded statement, with convincing statistics, that there is a dearth of doctors in the rural communities. It has been shown that in certain states and localities there are thousands of people without available medical service. Both of these citations touch upon the uneven distribution of medical service. Should inquiry be made it would be found undoubtedly that in the first instance ignorance, if not mental incompetency, prevailed and that those who should have been most concerned did not know enough to know that sickness existed, might be serious, could be cured and that aid was available. Most of us have encountered the like in our own experiences, in rural as well as in urban communities. You must blame the social worker, not the doctor, for such failures.

The second citation is best answered by pointing to the fact that in rural communities that are prosperous, in such as exist in Minnesota and

*Presented at the Annual Meeting of the Minnesota State Medical Association, Duluth, Minnesota, July 14, 1930.

adjoining states, there is no shortage of doctors. We may confidently predict that the five year investigation of the Committee on the Costs of Medical Care will prove this statement to be correct. No doubt there is a shortage in the abandoned farm districts and in the sparsely settled frontier fields.

While we are thinking upon this subject it is only fair to call your attention to the fact that the young folks leave the farms and the old folks do too, if they can, when the farm proves unattractive and unprofitable. That isn't the fault of the medical profession, it is the fault of our economic and social systems coupled with the inherent insufficiencies of humanity. A good farmer won't move his family into a territory where there are not good roads, good schools and churches. A doctor cannot be expected to do differently. Your merchants, tradesmen, white collar men all locate in prosperous places, and so do doctors. None of them except the social worker goes to the slums of the cities and the least prosperous of the agricultural localities to earn a living. The social workers are rendering a valuable social service in choosing this field, but they would be of far greater service if they strove to remove the causes of such conditions instead of attempting to correct the effects.

Poverty and illiteracy have much to do with insufficient and futile medical care. People must have comfortable living quarters, wholesome food, suitable clothing and a modicum of intelligence to benefit to the fullest by medical service. Without these, both preventive and curative medicine are of comparatively little value. It is true the very poor get more hospital service than do those with modest incomes. It would be impossible to treat the former properly in their homes. But upon leaving the hospital they return to the same squalid and unhygienic conditions of life, thus rendering futile a great part of the service they have received. The latter can be taken care of in their homes, and they are taken care of there, and well. Their homes are mostly favorable to health, therefore medical service in their case is not futile. Moreover, let it be said that not infrequently wealthy people, owing to stupid vanities and poor judgment, succeed in selecting for themselves very mediocre professional service. So let us explode the myth that the "very poor and the very rich alone receive adequate medical service."

That great class, including the $2,500 a year man and lesser wage earners, are the most numerous of our people. They are reasonably enlightened, housed, clothed and fed. The home and family life of many of them is charmingly beautiful. Their children, reared in an atmosphere of decency, frugality and self dependence, come to fill positions of trust and responsibility and are a challenge to the admiration and respect of the entire community. They become an honored example to be followed by vast numbers upon whom fortune has smiled more indulgently but, after all, less favorably. The great majority of the medical profession render a reasonably high average of service for a reasonable remuneration to this class of people.

The incidence of sickness is uneven; therefore the cost is unevenly distributed. The burden falls heavily upon a limited number of the sick population and lightly upon the rest. The source of complaint as to costs of sickness is to be found among the limited number who bear the heavy end of the burden. Thus it is to be seen that the trouble does not arise within the medical profession nor is it confined to the field of sickness only. Every family has unlooked for and unusual expenses at some time or other. With one family it will be a fire, with another a wedding, with another a lost job and continued overhead, while with still another it will be the cost of sickness and perhaps death and burial. When we consider this problem we must do so in relation to other costs and their distribution. We must not lose our sense of proportion.

It has been stated that the so-called middle class does not receive adequate medical service because of prohibitive costs. This leads to the query, "What is meant by the term adequate?" If those who use that term mean that every individual when ill shall be subjected to all the technical tests, a clinical examination by an expert clinician supplemented by examinations by a long train of specialists, then we will have to admit they do not. Furthermore, they never will, and if they did it would not prove to be adequate nor suitable. That kind of service, mass service if you please, is an ideal which, like the rose, has many thorns. Now, if by "adequate" we mean services rendered by well trained doctors such as have been graduated from our Class A schools for at least two decades last past and whose integrity and scholarly

habits are above reproach, then we must assert without fear of contradiction that adequate service *is* rendered, or is at least available.

Assuming for the sake of discussion that the costs of service are prohibitive, then we must determine why and proceed to place the blame where it belongs. To begin with, doctors' fees in Minnesota are reasonable excepting in isolated instances. This statement will be substantiated undoubtedly when we have the report of the Commission on the Costs of Medical Care. This lets the doctor out and an explanation for the complaint of high costs must be sought for elsewhere. There are many factors worthy of consideration, but only a few will be discussed. One which may be mentioned in passing is the nearly universal custom of our people to get, not that which they ought to get, but that which they most desire. It is ingrained in human nature to rebel against being compelled to accept something not wanted. People do not want sickness. They instinctively rebel against it when it comes. The expense incident to it, no matter how slight, is looked upon as a hardship, so they resent having to meet it even though, paradoxically enough, they settle with their doctor, hospital and druggist cheerfully and often with a genuine spirit of gratefulness. But, they complain of the very existence of such an expense just as they complain about having to pay taxes. The complaint has become accentuated because of the comforts and luxuries available and enjoyed by nearly all. It is due largely to the fact that there is a desire to use the money, and it is so used, for something else.

It is permissible to state that business and industry are very largely to blame for the complaint against the cost of sickness; for business and industry, while preaching thrift, have been inculcating habits of luxury and extravagance among the people. They have broadcast the slogan, "You must spend money to make money." While that is sound advice when the spending is for purposes of investment and trade, it is on the other hand most dishonest and demoralizing advice when applied to the purchase of articles that depreciate in value from the moment of acquisition. Business and industry have combined to sell goods, as is their function, and they sell without due consideration to the ability of the ultimate consumer to pay. How else shall we interpret the familiar advertisement, "You don't need any money, your credit is good?" Also the constant urge to "break down sales resistance" can mean nothing but utter disregard for the thrift of the buyer.

Partial payment buying has its advantages and has made many comforts, luxuries and necessities possible to us all, but it is not an unmixed blessing. Temptation set in the path of the possible buyer by the high pressure salesman cannot be successfully resisted by the average person. Consequently, the buying public has become heavily laden with personal indebtedness. When men are struggling under a burden of debt any compulsory additional burden brings resentment and protest. This holds whether the additional burden be due to unwelcome sickness or to the necessity of replenishing the coal bin for the winter. It is not the fault of the medical profession that the people are in debt and have difficulty in meeting their obligations. Their indebtedness is due to the greed and short-sightedness of business and industry coupled with the natural weakness of human character. Business and industry have not yet learned how to know when the purchasing power of the people is becoming strained, or they have not yet developed sufficient intelligence to enable them to regulate their production and distribution with such balance as to maintain a natural demand, steady consumption and a maximum of steady employment.

This brings us to the problem of unemployment in relation to the cost of sickness. When men are idle they complain most bitterly of illness and its possible costs. They resist the incurring of debt, not knowing where they are going to find the means with which to pay.

The reduction of purchasing power is only one of the many causes for unemployment. The business world stands in close relation to it. The merging of business interests, the spreading use of labor saving machinery, the chain store movement and all similar devices have sought to effect a saving at the expense of the numbers employed and without any evidence as yet of absorption of the unemployed into other occupations. These efficiency devices mean increased production at less cost but incidentally, in company with indebtedness, they sacrifice the market by reducing purchasing power.

Another field in which industry has engaged to benefit mankind is the "safety first" move-

ment. We doctors have been enlisted to aid in this beneficent movement and right royally and loyally have we responded to the need, glad indeed if we can aid in preventing human suffering. But the movement is not an unmixed blessing any more than is the partial payment scheme, for it appears that indemnity insurance companies, with an eye to business, have discovered that modern machinery is very dangerous to men who can no longer keep in step with the rapidly moving and untiring machine. Upon careful study it has been found that the age at which man does not move in unison with the machine is for all practical purposes about forty and up. These same astute companies have also learned that men who have been injured in certain degrees, or employees who have begun to suffer slightly from the inevitable breaking down processes of life, or who show signs of requiring a lightening of their labors from any cause, are no longer safe to have around the shop. They might get hurt. Well, what to do? The simplest thing in the world of course is to raise the premium paid by the employer if he persists in having such risks around. Or, what amounts to the same thing, a reduced premium will be charged if the employer retains in his employ only men of sound body and suitable age such as are fit to meet the machinery requirements. Oh! the safety first campaign in industry is a wonderful thing in some respects. It seems that it is far better for a man to starve to death while hunting a job that can't be found than it is for him to be hurt in the pursuit of duty and at the expense of an indemnity company. So there we have the source of another goodly number of idle men who will very justly complain of doctors' bills even though they be of trifling amount. It isn't the doctor's fault that workmen are out of work. Neither is it the doctor's fault that office men are out of work in the great cause of efficiency and that for the same reason the small banker and independent retail store men are out of business. The doctor knows that all these people who suddenly find themselves without means of livelihood are going to have sickness along with their other troubles and he stands ready, as he always has, to step into the gap and aid in stemming the tide of trouble.

That the greater the number of people who are removed from gainful occupation, the greater will be the medical and tax costs of those who are so employed is a self evident fact requiring no elucidation. The first point at which the public and the private charities will have this fact brought forcibly to their attention will be in the field of old age pensions. The question of old age pensions has engaged the attention of statesmen, politicians and organized charities for a considerable period of years. All seem to have agreed that sixty-five is the age for retirement. They will have to reduce that limit to the earlier age of forty if the present trend in the employment field continues. A disturbing thought intrudes itself at this juncture. Men at the ages of forty, forty-five and fifty are still possessed of power of procreation. Our pensioners will be fathering children born in poverty to be provided for out of our poor funds. This increase will make nice additions to our population. Another serious health problem will develop in association with the old age and idle men's pension system. Idleness fosters degenerative disease and we may expect a whole new crop of arterial disorders to appear far ahead of their normal time. Not only will physical decay begin at an earlier age than heretofore but cerebral arteriosclerosis with its mental failure will become much more prevalent than it is at present. What effect this may have upon the average age of life we are at liberty to guess. It is reasonable to suppose that the work that has been so successful in saving the lives of our children, and thereby raising the average age of life, will be neutralized, in so far as the latter gain is concerned, and the average reduced.

One more cause for complaint is the occasional predatory physician. The man who has an hypertrophied opinion of the value of his services, who has no sense of his social obligation, who charges working people fees out of all proportion to their ability to pay. He is a disgrace to the profession. If he cannot afford to treat the common people for reasonable fees then let him confine his activities to the wealthy classes, if the latter will have him, and relinquish what to him is an unprofitable practice to his equally competent but more honorable brothers. That "God tempers the wind to the shorn lamb" is something beyond his comprehension.

It would appear, then, that chief among the causes giving rise to the complaint against the cost of sickness are poverty, ignorance, moronic

mentality, greed for gain, extravagance, debt, unemployment and the occasional predatory physician. But no matter what the causes are, the plain fact is that they do exist. The problem is to know how to cure these festering spots on the body politic. To cure them will be to remove most of the ills which afflict our present civilization. Humanitarianism, which aims to tide people over difficult periods and to place them in suitable positions for self support, is commendable and helpful but certainly not curative. Paternalism, which is nothing other than governmental dictatorship applied to the personal activities of the private citizen, is worse than useless. It would encourage the support of an ever increasing number of idle people, tend to destroy initiative and to build up class distinctions. It would accentuate the trends of the rich getting richer and the poor getting poorer. Pick up your dictionary and study the definition of paternalism. Then turn to your encyclopedia for a detailed study of its origin and history. With a full understanding as to its significance you will stand aghast as you contemplate the riot it is running in this country today. You will feel the need, as never before, of a solidly united profession to contest this monstrosity at every step of the way. Socialism, a term that has been used most loosely, may be defined as a political philosophy which contemplates the substitution of coöperation for competition with an equal distribution of the proceeds. Well, if all men were created equal, physically, mentally, morally and spiritually, perhaps socialism might be made to work. Inasmuch as all these qualities obtain unequally among us, it ought to be manifest that socialism cannot work. It is the very inequality of mentality that makes possible the thought on the part of some that socialism is practicable.

The solution of our problems rests in a recognition of the principle that every individual, every organized or unorganized group, whether rich or poor, owes certain obligations to society. You cannot single out any special group, whether it be the profession of medicine or some other body, and burden it down with duties to be performed, willy nilly, for the benefit of another group and expect relief. Such a course is paternalistic and, so far as medicine is concerned, oppressive; so far as the people are concerned, demoralizing in the extreme. While recognizing the principle of social responsibility we must none the less remember the importance of individual privilege and personal freedom. These must be preserved or the nation fails.

What the attitude of the medical profession shall be in relation to the changes taking place about us affords food for serious thought. That paternalistic encroachments have taken place is only too apparent. Especially is this true in foreign places, so much so indeed that the movement appears to be well nigh world-wide in its scope and its tentacles are reaching hungrily into our own country. It has gathered such impetus now that only a solidly organized and militant profession will be able to ward it off or so modify it as to eliminate its most pernicious features. The profession must be prepared to meet contingencies as they arise and make proper adjustments. Any trend or action tending to discourage personal initiative must be checked. Fair compensation, commensurate with the kind and quality of services rendered, must be maintained. We must "render unto Caesar those things which are Caesar's," but Caesar must render unto us those things which are ours.

The profession will not be able to successfully combat the dangers that threaten it unless it respects itself. To respect itself it must be deeply interested in its work. The degree of this interest can be measured by the general average of ability manifested by the profession in its general affairs. Thanks to the combined influence of the association of American Medical Colleges, the Council on Medical Education of the American Medical Association and the various state boards of medical licensure, the average training and inherent ability of the physician has steadily risen within the last twenty-five years. There is every reason to believe that present standards will be maintained and that the excellent quality of mentality now so apparent in the ranks of the profession will continue and become more apparent as time goes on.

It is not conceivable that men of that type will permit themselves to be placed in a position of servitude, so borne down with petty duties and so poorly remunerated that there is left neither time nor means with which to keep their knowledge and skill abreast of the best of their time. The public are insistently demanding the best in medical skill. They cannot get it by reducing the medical profession to a position in which it

is neither happy, comfortable nor self-respecting.

Our duty to ourselves and to society is to continue to maintain our high standards of efficiency; to continue, individually and collectively, to minister to the needs of sick humanity wholeheartedly and with broad sympathies, just as we have been doing since time immemorial; to continue to keep ourselves banded together for the purpose of maintaining our high ideals. The old family doctor is not gone from our midst. His pill boxes, his saddle bags, his faithful old nag are gone, but the spirit that was his still lives and carries on. Human nature does not change. It craves sympathy and understanding today just as it did fifty and a hundred and a thousand years ago. The old family doctor because of his indomitable will and great purpose in life survives and has steadily adopted improved methods of therapy as rapidly as science has made them available. He still lends a sympathetic ear, still pours oil on the troubled waters, still advises and guides in matters so intimate that none other can be admitted to confidence. Let us not mistake the discarded clothing and accoutrements of the old family doctor for the man himself. Let us ever cherish the ideal of him, so indelibly and picturesquely stamped upon our memories; let us emulate his hardy and humane virtues, always.

And now, in conclusion, we may say that as a people we are the victims of our own intelligence and insufficiencies. Our intelligence has enabled us to pry into and learn the secrets of nature and we have adapted them to our own uses. We have developed all sorts of useful and enjoyable contrivances. We have shortened space and made time of no consequence. We have rendered life more complex but altogether more comfortable. But we have not yet learned how to use our newly discovered good fortune rationally. There is no similar experience in the history of the world, one in which a whole nation of people have become mad with a superficial material prosperity, to which we may turn for guidance. Certain fixed and immutable laws of life and conduct exist, it is true, but in the exhilaration incident to our material gains we have forgotten the spiritual and philosophical. We are caught in the mad onrush of what we call progress and our insufficiencies cloud our mental vision. We see dimly, if at all, into the significance of the turmoil in which we live. We vision problems but we fail to determine just what they are or how to solve them. We are caught in the current of a turbulent stream, being swept on whether we will or no and we haven't the faintest idea as to where we are going. As we go we struggle to keep from going under, enjoying the struggle with the exuberance of youth, but hoping nevertheless that calm waters are just ahead. When we reach them we shall have had experience, perhaps we shall have been chastened thereby, and we shall then have time for retrospective thought. We shall have gained perspective.

The prehistoric American may have been the last of a decaying race, or he may have been in the infancy of his development. We do not know. We do know that we are here in his place, in an entirely new and different world. We do not know whether, in relation to our modern life, we really are growing or beginning to go backward. The signs of decay are not wholly lacking, but let us hope that the signs of our social and political life are correctly interpreted when we speak of ourselves as an adolescent nation. We at least flatter our vanity when we accept that designation, for it presages future growth and development.

PRIMARY CARCINOMA OF THE LUNGS AND BRONCHI*

E. V. Goltz, M.D.
Saint Paul

IT HAS happened that I have encountered primary carcinoma of the lungs and bronchi with increasing frequency during the past few years, both in private practice and on my service at the Ancker Hospital. In fact, since I have been interested in this condition there is scarcely a month goes by without word of another primary lung cancer.

In checking up at the Ancker Hospital we could find only two cases where death had been caused by this type of cancer from 1912 to 1917, while from 1918 to the present time there were sixteen such deaths. No doubt there were more; some not diagnosed, others diagnosed but not submitted to autopsy examination and hence not proven cases as to primary or secondary growth.

This apparent local increase is noted by many authorities both in this country and Europe and some of the references as to its incidence are of interest.

Moses Barron, reporting from the records of the Department of Pathology at the University of Minnesota, states that no cases were found prior to 1912; that there were four cases or .2 per cent from 1912 to 1918 and nine cases or .9 per cent from 1919 to 1922, among a total of 4,362 autopsies, with the greatest increase during 1918 and 1919, which was the peak of the influenza epidemic.

His collected statistics in 1922 indicate also a gradual increase from .057 per cent in 1878 to .46 per cent in 1916, practically ten-fold.

Various hospital reports in this country and Canada show a marked increase in percentage of these carcinomata in total autopsies, as well as of lung carcinomata to total carcinomata since 1900, with the greatest increase since 1915.

London hospital statistics show .51 per cent in 1907, increasing to 2.05 per cent in 1925. German statistics show an average increase very similar to the foregoing with a corresponding percentage increase in lung cancer to total cancer, and generally conclude that there has been a definite increased incidence of primary carcinoma of the lungs in recent years.

Berblinger, in Jena, where the majority of deaths are followed by autopsies, found a definite increase of primary lung cancer in recent years.

Erdheim, of Vienna, where practically all deaths are followed by autopsy, states that there is a marked increase since the World War.

Taking for granted the increased incidence of primary carcinoma of the lungs it is of considerable interest to determine, if possible, if this increase is apparent or real.

The following observations favor the apparent increase:

1. Increased human longevity. The average length of life, prior to the fifteenth century, is said to have been eighteen years. This increased to forty-five years at the beginning of the nineteenth century. At present it is about fifty-seven years, ten of which have been added during the last two decades, with the resulting increase in the "cancer age."

2. Alterations in pathological classification as the result of which previously termed sarcomata are now classed as carcinomata.

3. Improved diagnosis with the resulting increase in autopsy check.

4. Improvement in sociological conditions leading to larger attendance at hospitals.

To offset these arguments favoring the apparent increase only, one can say:

1. The percentage of primary lung cancer compared with the total cancers has increased three or four times.

2. The lung tumors formerly classified as sarcomata are really rare.

3. A great number of lung carcinomata are still found only at autopsy.

4. The hospital routine of the Old World has not varied to this extent in the last twenty years. Consequently one is impressed with the thought that this increase is actually a real one and that it is in some manner due to etiological conditions.

ETIOLOGY

When the cause or causes of cancer in general become known we will be better able to explain this marked increase in primary lung cancer. However, since this increase recently over other

*Thesis presented before the Minnesota Academy of Medicine, St. Paul, April 9, 1930.

forms of cancer we may look for those etiological factors of a chronic irritative nature which themselves have shown an increased incidence in recent years.

Fig. 1. Case 1. August 11, 1926. Large tumor involving almost entire right lower lobe; no evidence of fluid or metastases.

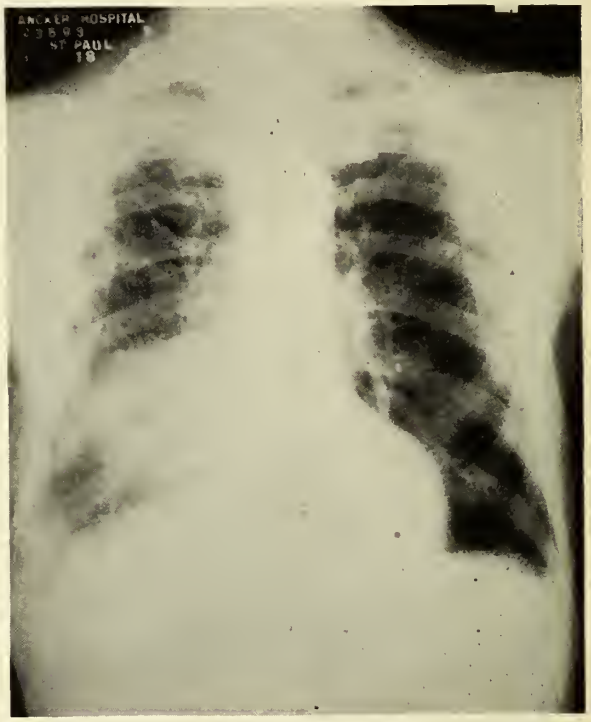

Fig. 2. Case 2. March 18, 1929. Large fairly localized tumor extending from the right border of the heart into the base of lung, with probably atelectasis of the lower lobe. No fluid or metastases.

These may be grouped as: (1) Bacteriological; (2) chemical; (3) mechanical; (4) possibly radiological.

The chief bacteriological factor is probably influenza. Statistical evidence points to a definite increase of lung cancer following the great epidemic of 1918 and 1919 and histological examination by various authorities (Askanazy-Goldzieber and Myer) suggest changes resembling precancerous epithelial proliferation in the lungs in influenza.

Chronic bronchitis, bronchiectasis, fibroid pneumonia, healed tuberculosis and syphilis may predispose. The majority of observers everywhere note the great increase in lung cancer during and after the epidemic of 1918 and 1919.

Chemical and mechanical irritation is largely by way of inhalation. Long continued inhalation of tobacco smoke must be considered, although as yet there is no definite proof of this. Road dust, containing tar, may prove to be a potential factor.

Kimosa has produced lung cancer in rabbits and guinea pigs by insufflating tar through a tracheotomy wound in his experiments. Half a million tons of tar are used annually on the roads of this country and the fact that carcinoma of the lung is very rare in places like Hong Kong and Singapore where the roads are not tarred is suggestive. The fumes of motor exhaust are mentioned by many, but as yet there are no proofs. Workers in mines and other dusty occupations in certain regions show a definite increased incidence; thus, in Schneeberg, Saxony, it was claimed that 50 per cent of the old miners died of lung carcinoma. The Saxony Cancer Committee *x*-rayed 154 cases of long-time mine workers; twenty-one of these died; thirteen of these deaths were from lung cancer, as confirmed by autopsy, and two were diagnosed as such but did not come to autopsy. This was in marked contrast to the rest of the population, in whom there was practically no lung cancer. The arsenic contained in the cobalt and bismuth mined was thought to be the principal etiological factor.

Finally, "gassing" in military service is mentioned as being a factor in the marked increase since the war.

PATHOLOGY

Many observers classify primary lung cancer as arising from: (1) The columnar epithelium lining the bronchi; (2) mucous glands of the bronchi; (3) squamous alveolar epithelium.

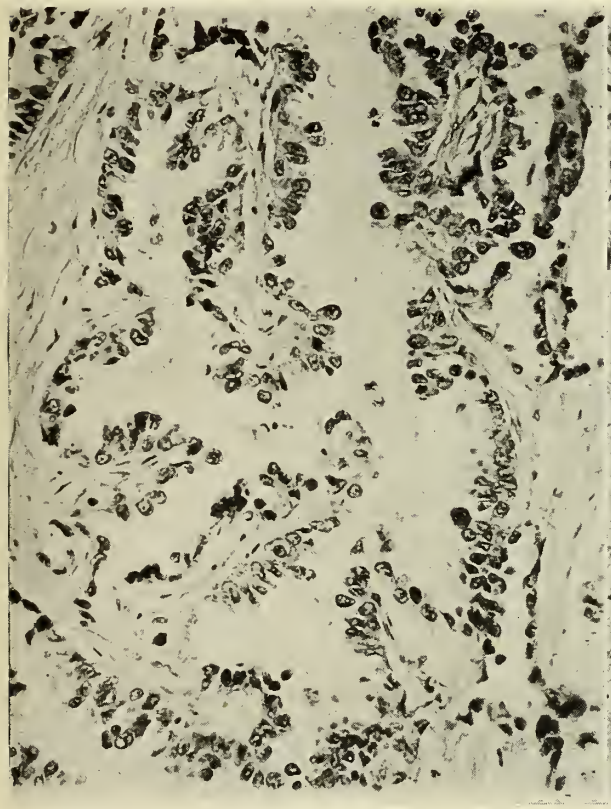

Fig. 3. Case 2. Microscopic section of lung tumor. Marked tendency to glandular structure with various types of epithelial cells.

Fig. 4. Case 2. Microscopic section of liver with similar glandular formation and massing of epithelial cells.

This distinction is difficult in many instances as the type is largely determined by the character of the cells composing the tumor mass and these may vary from squamous in some portions of the tumor to cuboidal in others. Metaplasia is easily produced in these cells by chronic inflammation and is spoken of by Hanseman as "histologic accommodation." Most authorities believe that the great majority of these tumors arise in the mucosa of the bronchi. Erdheim in 1926 stated that they were all bronchogenic but that they were prone to metastasize in the lung.

1. The type arising from the bronchial epithelium may vary greatly in size, color and consistency. It may remain as a small projecting mass in the bronchus and yet may have metastases to the liver, kidney, adrenals, etc., or it may grow into the lung tissue and displace it even to the extent of an entire lobe. Occasionally its growth will be found between the lobes only, and overlapped by them. In the late cases in which the tumor mass has attained large size and has caused much distortion it may be difficult to determine the exact point of origin in the bronchus but careful search will usually reveal a fungoid ulcerating growth in its wall. Sooner or later there is obstruction to the bronchus; if this is partial there will be dilatation of the distal portion of the bronchus from retained secretion and bronchiectasis results which may go on to abscess formation. If obstruction is complete atelectesis results. Broncho-pneumonia finally complicates the picture and is usually the immediate cause of death.

2. The type arising from the bronchial mucous glands is rare and usually limited chiefly to the walls and especially the sub-mucosa of the bronchi. These tumors and their metastases are characterized by excessive mucous secretions and are more or less slimy in appearance. I have not seen this type but Klotz reported two cases and Weller states that they are not infrequent.

3. Those arising from the pulmonary alveoli may be diffuse, involving the larger part of the lobe, or multiple and nodular, involving a single lobe or the entire lung. Ewing states that these masses are often composed of cuboidal pleomorphic epithelial cells, simulating cells found in the tumor arising from bronchial mucosa. There is, therefore, great possibility that many of this type are metastatic and are primarily bronchiogenic, especially if they are multiple and of rapid growth. Pleural involvement directly by extension or metastasis, with pleural effusion, occurs in about one-half of the cases, and approximately one-third of these effusions are bloody. Rapid recurrence of this bloody fluid is characteristic. Erdheim reports elevation of the diaphragm frequently and thinks it due to paralysis resulting from phrenic nerve involvement. It is quite possible that this may also be a result of extensive lung atelectasis.

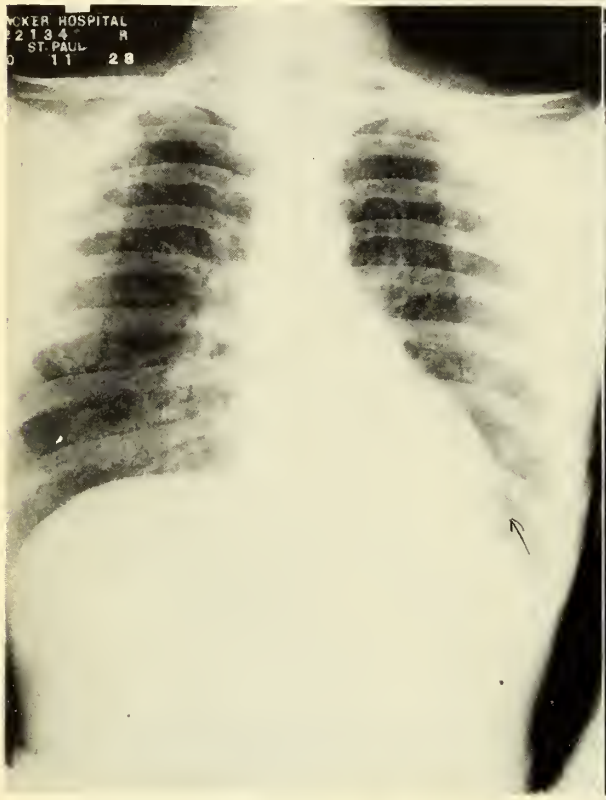

Fig. 5. Case 3. October 11, 1928. Apex of tumor just visible beyond heart shadow but not interpreted as such at this time.

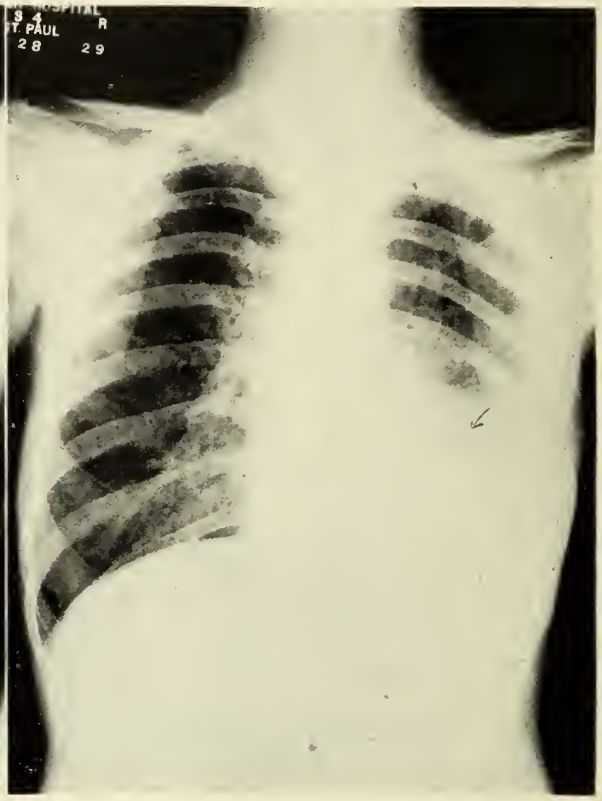

Fig. 6. Case 3. October 28, 1929. Large diffuse tumor mass. Same case one year later.

METASTASES

Primary carcinoma of the lung is very prone to metastasize, and its metastases are widely distributed. This is due to the fact that the tumor growth is slow, allowing time for metastases before death, and also because of the abundant supply of blood and lymph vessels in this region. The regional glands are most often involved and the extrathoracic glands next. Of the viscera the liver and suprarenals are the favorite sites with the pancreas next. The parietal pleura often shows metastatic involvement but may also suffer from direct spread. The vertebral column and according to Erdheim the proximal ends of the long bones, especially the femur, are frequently affected and are often overlooked at autopsies because of the difficulty in obtaining consent to osseous dissection. Of unusual interest is the high percentage of brain metastases as compared with cancer elsewhere in the body. This is explained by the fact that the cells from the lung are carried by the blood stream directly to the brain while metastatic cells from elsewhere in the body are largely sieved out by the lungs and never reach the central nervous system. Because of this marked tendency to early and frequent cerebral metastasis the first marked symptoms may be those of brain tumor and may easily

undergo operation. Occasionally metastases occur in the lung apart from direct spread and may be mistaken for the primary growth. The rapid increase in size and number speaks for metastases.

SYMPTOMS AND SIGNS

Age and Duration. The majority of the instances occur between the ages of forty-five and sixty-five and the average duration is seven months. The youngest proven case by Simpson was thirteen and the oldest seventy-seven. The shortest duration, reported by the same author. was three days, while he reports four cases living four years. Males predominate over females three to one.

The first symptoms may come on suddenly with hemorrhage or may resemble acute pleurisy or pneumonia, or they may be gradual in onset with cough, pain and dyspnea, and may be treated for bronchitis over a period of months. Finally this cancer may be entirely latent and be manifested by its metastases in the brain, bones or viscera.

The physical signs are always confusing at best. In early bronchial tumor, with most distressing symptoms, chest examination may fail to explain them. On the other hand, there may be present all the signs of broncho-pneumonia, atelectasis, bronchiectesis, lung abscess and pleural exudate, depending on the location, size and complications of the tumor.

Cough is the most frequent symptom but may not appear at all and may or may not be characteristic. However, recurring paroxysms of cough with intense discomfort, pain and dyspnea ending with only a small amount of mucous, sometimes blood-tinged and continuing day and night should be strongly suggestive of bronchial cancer, especially when this occurs in an individual in the cancer age.

Sputum is usually scanty and mucoid early, becoming muco-purulent or bloody and more abundant as infection and complication supervene.

Pain next to cough is the most important and the most frequent symptom. It may be of all grades of intensity and of various types. The site of the pain is usually the chest but may be referred to the neck, back, abdomen, legs or arms and may be due to various causes, as nerve pressure, pleural irritation, pericardial inflammation and cord and nerve plexus involvement.

Wasting occurs in 50 per cent of the cases and may begin early.

Fever is often found early, though low grade until complications arise.

Fig. 7. Case 3. Cross section left lung six weeks later.

Dyspnea may occur early with cough, later it is influenced greatly by the degree of obstruction to the bronchus or pressure on the lung from the tumor growth, pleural fluid, etc. It may occur in paroxysms resembling asthma.

Less constant symptoms are cyanosis, dilated veins due to pressure in the mediastinum with or without local edema of the head, neck or upper extremity. Laryngeal paralysis and dysphagia may occasionally occur as may unequal pupils and occasionally clubbing of the fingers or other signs of pulmonary osteoarthropathy in lingering cases.

Leukocytosis much over 12,000 is only present in the later cases and is due then to an associated infection.

DIAGNOSIS

This is often difficult and many so-called "silent types" are easily overlooked and are only found at autopsy after their metastatic activity in the brain, bones or other distal parts has become the center of interest to all concerned.

Fig. 8. Case 3. Low power. Microscopic section.

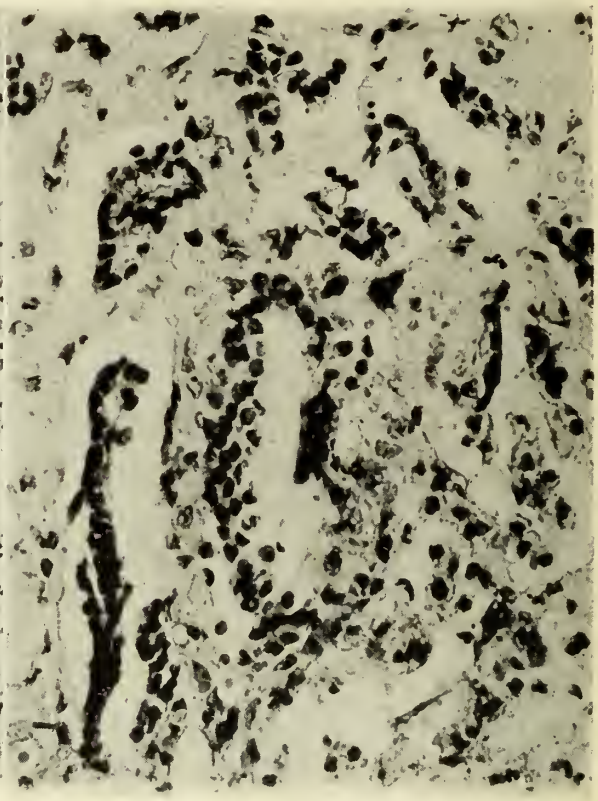

Fig. 9. Case 3. High power. Microscopic section.

A careful history will usually bring out one of the cardinal symptoms and focus attention on the lungs so that the course and physical signs, together with the special examination by the bronchoscope, *x*-ray and intrabronchial injection of lipiodol will give conclusive evidence. The sputum will occasionally furnish the diagnosis with tissue shreds. Biopsy through the bronchoscope, if possible, gives the most conclusive evidence. This is also true of superficial glandular biopsy, but, unfortunately, while tuberculous glands in the neck usually mean very little pulmonary involvement, in the case of carcinomatous glands, autopsy shows extensive lung lesions. While it often happens that the primary growth in the bronchus is overlooked and its metastases discovered, so also certain metastatic lung tumors are called primary because their inconspicuous parents in the thyroid, thymus or prostate are slower of growth than their offspring.

Physical signs are often indefinite early; generally speaking malignancy of the lung should be considered when either incessant cough, pain, dyspnea or blood-tinged sputum occurs in an individual of the cancer age without satisfactory explanation. Repeated *x*-ray films, both anterioposterior and lateral should be had, and bronchoscopic examination should be insisted upon after first ruling out aortic aneurysm. Bloody pleural fluid means malignancy in practically all chronic cases not associated with trauma.

TREATMENT

The treatment for this condition demands early diagnosis and since carcinoma of the lungs is usually carcinoma of the larger bronchi, local cautery and possibly radium by a skillful bronchoscopist offers the best hope. Brunn found there were at least twenty-eight cases of lobectomy and other surgical interventions in the literature. Sauerbuch had one patient living five years and another three years after operations; obviously the cases must be carefully selected.

Deep *x*-ray therapy is useful at times to relieve pain, but, while subjectively of benefit, progress is not affected.

I have selected the following three case reports which represent various clinical pictures with *x*-ray films, slides and gross specimens of the last two:

Fig. 10. Case 3. Secondary hypertrophic osteo-arthopathy; clubbing of fingers with spurring of terminal phalanges and periosteal proliferation along carpal and metacarpal bones.

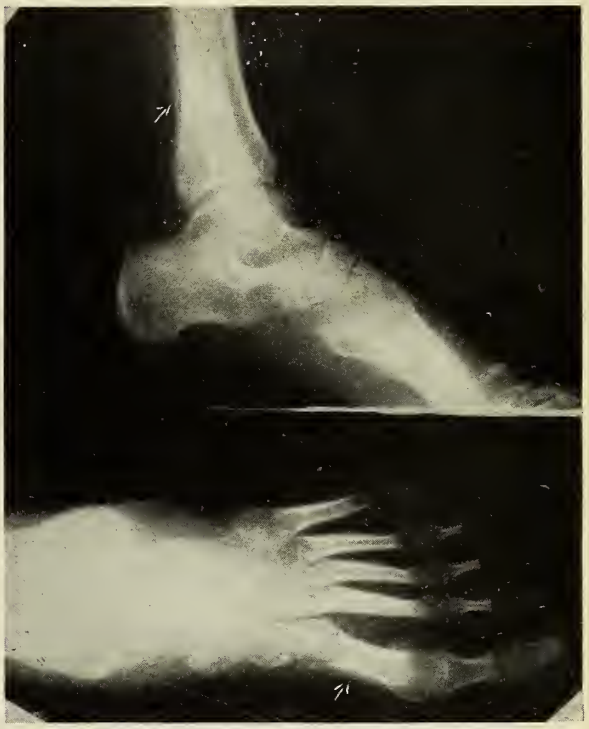

Fig. 11. Case 3. Similar changes in the foot.

Case 1.—A male, aged 61, by occupation a printer, was first seen November 15, 1926. He complained of severe paroxysms of cough, slight dyspnea on exertion and pain in the chest present for the past four weeks with loss of ten pounds in weight. The cough was more less characteristic in that it occurred in frequent prolonged paroxysms with much dyspnea, moderate cyanosis and pain in chest, ending finally with the expectoration of a small amount of sticky, mucoid material which was occasionally blood-tinged. He also complained of occasional pain on swallowing food. He had had influenza in 1918.

The esophagus examined with thick barium under the fluoroscope and was normal. The heart outline was somewhat enlarged to the right and the right lower lobe was as is seen in Figure 1. The afternoon temperature was 99.2; pulse 90; respiration 28. The red blood cell count was 4,000,000; the white count, 8,200. A tentative diagnosis of lung cancer was made, and bronchoscopic examination advised. A biopsy specimen proved to be carcinomatous. Deep *x*-ray therapy seemed to diminish the size of the mass and to relieve the pain, but the course was progressively downward. He developed pleural pain, bloody pleural fluid and an active pericarditis and died March 21, 1927. Autopsy showed no other primary cancer and no metastasis except in the regional glands and in the pleura.

Case 2.—This patient complained chiefly of stomach trouble and pain in the kidney region and was admitted to the Ancker Hospital on March 13, 1929, with a provisional diagnosis of gastrointestinal malignancy and arteriosclerosis. He was a laborer seventy-five years of age. His chief complaints on admission were weakness, dyspnea, loss of twenty pounds in weight, constipation, pain in the right kidney region and epigastric distress. Four months previous to admission he had had an appendectomy and was well for a month. Three months prior to admission he developed influenza and had coughed and raised considerable sputum since that time. There had been no hemoptysis. Two weeks prior to admission his abdominal pain had become worse and continued to be his chief complaint until his death on May 21, 1929.

The liver was palpable and nodular and a definite area of consolidation could be outlined just to the right of the right heart border, and corresponding to the inner one-half of the right lower lobe. *X*-ray of the gastrointestinal tract was negative and the chest film on March 19, 1929, showed a large fairly localized shadow extending from the right border of the heart into the base of lung, with probably also some atelectasis of the lower lobe. During the stay in the hospital he developed bloody sputum and had several small hemorrhages and later also a bloody pleural fluid which recurred rapidly after aspiration. It was only a few weeks before death that he complained of pain in the right chest. The red blood cell count was 4,000,000;

white, 8,000 until one week before death, when it reached 10,800. A diagnosis of primary lung cancer was made. Autopsy verified the diagnosis and in addition metastases to the liver were found.

*Case 3.**—This case represents one of the so-called "silent type," with no or very few symptoms suggestive of lung pathology. Many of this group are only diagnosed at autopsy. A female, aged 42, a housekeeper, was admitted to Ancker Hospital, October 9, 1928. She left under protest November 28, 1928, with a diagnosis of pulmonary osteo-arthropathy and mitral regurgitation. Her history stated that her hands, feet, wrists, ankles, and knees had been painful and slightly swollen since last April. Also, that since the onset of her illness she had lost thirty pounds in weight and had lately developed a dry unproductive cough. One year ago she had had a severe bronchitis from which she recovered, after which the joints became painful and swollen. After leaving the hospital she was treated outside for infectious arthritis with the removal of her tonsils and teeth. She did not improve, however, and was readmitted in October, 1929, having slowly failed since leaving the hospital the previous November. The joint trouble at this time was still the principal complaint but she still had the dry, unproductive cough and had lost more weight and was quite weak. On October 29, 25 c.c. of thin bloody fluid was aspirated from the left pleural cavity. The red blood cell count was 4,000,000, white 8,400, and Hb 70 per cent. The course was progressively downward; she died December 13, 1929. Autopsy showed primary carcinoma of the left bronchus with involvement of the diaphragm and parietal pleura.

Fig. 12. Case 3. Same periosteal proliferation in the tibia and fibula, showing absence of joint involvement.

*Osteo-arthopathy—The rheumatic complaints of Case 3 were apparently on a pulmonary arthopathy basis. Wells reports references to this condition in thirteen cases out of ninety selected at random and states that there is a definite hyperplasia of the pituitary gland. Brunn actually found metastases in this gland in one case.

The close association of the changes in this condition to those of acromegaly warrants a more careful examination both macrascopically and microscopically of this gland at autopsy in these cases. (Figs. 10, 11, 12.)

THE CHILDHOOD TYPE OF TUBERCULOSIS

Eugene F. Johnson, M.D.
Nopeming, Minnesota

MUCH has been written, recently, about the relation between the adult and childhood types of tuberculosis, and the outstanding work in this field has been done by Chadwick,[1] McPhedran,[2] Myers,[3] and Opie et al,[4,5] who have published their conceptions of this relationship.

This paper does not represent any new work, but will illustrate further and in a way bear out the observations of the men mentioned above.

All of the cases to be cited and illustrated have been or still are patients at the Nopeming Sanatorium.

The essential differences between the adult and childhood types of tuberculosis as shown by the previously quoted authors are as follows:

The childhood type is the result of a primary infection with the tubercle bacillus and for this reason it is the type of tuberculosis that occurs usually in children and only rarely in adults, while the adult type of tuberculosis is the result of a reinfection and is the kind of tuberculosis usually found in adults and only rarely in children.

The initial or primary infection may be localized in any part of the lung, whereas the reinfection lesions usually are localized in the apices and extend along the pleura. The first clinical manifestation, however, is often below the clavicle.

The associated tracheobronchial lymph nodes are always involved in the childhood type although this may not always be demonstrable, while in the adult type these glands are not involved except occasionally in the terminal stage.

Caseous lesions in the primary infection type usually become calcified or encapsulated in fibrous tissue, whereas this kind of lesion in the reinfection type is followed by excavation or fibrosis, or both.

Infiltrated areas commonly resolve, leaving trivial or no scars except for foci of caseation which calcify in the childhood type while in the adult type infiltrated areas resolve with the production of more or less fibrous tissue.

The primary infection carries with it a good prognosis, while the prognosis of the reinfection type is poor if it occurs in children or adolescents.

Bearing these differences in mind, it is also noteworthy to consider the fact that the tuberculin reaction is 80 per cent positive in children of families where there is an open case of tuberculosis and only 20 per cent positive in children of families where no tuberculosis exists.[4, 5]

This knowledge becomes important when we realize that over 50 per cent of boys and girls in the teen age with the adult type of tuberculosis also have definite evidence of a previously existing childhood type of tuberculosis manifested by calcifications present in the lungs.

We present, as further support of the above mentioned facts and differential criteria between adult and childhood types of tuberculosis, the following cases of primary tuberculosis in children and in one adult.

Case 1.—B. H., a white female, four years of age. The mother has tuberculosis, also a sister, both of whom are in the Sanatorium. This child has always been very well and active, but because of contact with her mother, she has been under close observation. She is entirely free of symptoms, temperature and pulse are normal, and she is very well nourished and even overweight; physical signs are absent. Mantoux test strongly positive with 0.01 mgm. tuberculin. Figure 1 shows a sharp inflammatory reaction in the right upper lobe surrounding a dense outgrowth from the mediastinum, which is in all probability a lymphadenitis.

This case illustrates tuberculosis of the tracheobronchial lymph nodes rather massive in character, and falls into lesion F of McPhedran's[5] classification of pulmonary lesions in childhood and adolescence. The prognosis in this case is serious, because of the danger of caseous pneumonia or miliary tuberculosis developing.

Case 2.—L. A. K., a white female, three and a half years of age, has been at Nopeming Sanatorium eight months. The mother died of tuberculosis. The patient has never had any symptoms of disease. Physical examination is negative, except for a small area of impaired resonance just below the left clavicle. The von Pirquet test is 3 plus. The child is growing rapidly, and is overweight for her age and height. The lesion was accidentally discovered in the course of a routine examination, which was made because of exposure to the mother. *X*-ray of the chest, shown in

Figure 2, reveals a rather diffuse, massive, childhood type of tuberculous infiltration at the level of the left clavicle.

The prognosis in this case is good unless the lesion progresses. Associated, demonstrable, uncalcified nodes, especially if multiple, would indicate a grave prognosis. There is danger that a confluent bronchopneumonia or a miliary tuberculosis may develop.

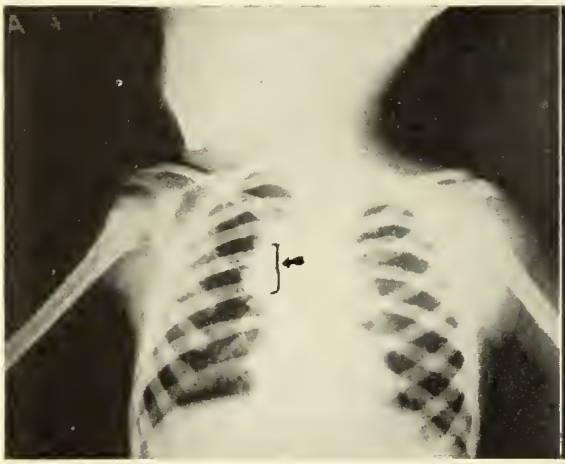

Fig. 1. Hilus enlargement.

Fig. 2. Diffuse childhood type of tuberculous infiltration.

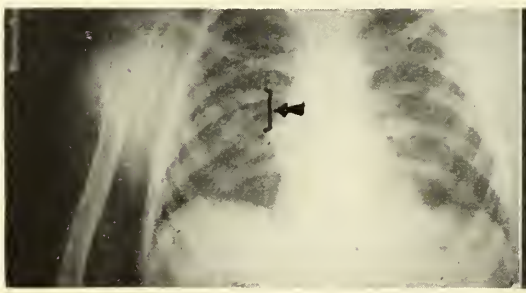

Fig. 3. Diffuse childhood type of tuberculous infiltration.

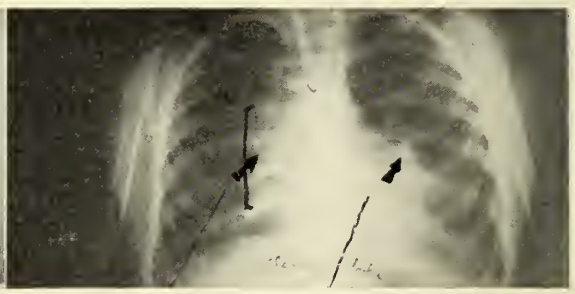

Fig. 4. Calcified node (*left*). Blurred cardiac margins (*right and left*).

Case 3.—J. S., a white male, five and a half years of age, has been at Nopeming three years. The father has tuberculosis and is also at the Sanatorium. Symptoms began in this boy in 1926 following an attack of bronchopneumonia. A persistent cough followed with a moderate loss of weight. Chest examination in 1927 showed impaired resonance on the right side toward the base, suppressed breath sounds, but no râles. The von Pirquet test is strongly positive. At the present time he is gaining weight, has no symptoms, and is growing steadily with no positive physical signs. *X*-ray examination shows a diffuse tuberculous infiltration which is of the same type as shown in Figure 2.

The photograph of this *x*-ray (Figure 3) does not show the lesion as well as the negative.

Case 4.—C. K., a white male, nearly four years old, has been at Nopeming one year. The mother died of tuberculosis. Symptoms began one year before admission with a persistent, productive cough. Expectoration was profuse and consisted of purulent material. There was a history of frequent respiratory infections and failure to gain weight.

Examination of chest shows impaired resonance at both bases, exaggerated breathing and coarse râles. The von Pirquet test is strongly positive. At the present time the child is doing very well, but still coughs slightly and raises small amounts of purulent sputum early in the morning. Weight and temperature are normal. Sputum has always been negative. Guinea pig inoculations were negative.

X-ray of the chest (Figure 4) shows blurring of both right and left cardiac margins due to chronically dilated bronchi characteristic of bronchiectasis. At the level of the third rib, anteriorly, next to the cardiac margin on the left side, is a discrete, circumscribed area of increased density due to a calcified, tuberculous, hilus lymph node.

This is the same type of childhood tuberculous lesion illustrated in Case 1, plus bronchiectasis.

Case 5.—S. K., a white female, 14 months old, has been at the Sanatorium two and a half weeks. The mother has advanced tuberculosis, which was diagnosed before the child was born. After the birth of the child,

the mother was advised by a doctor to nurse her child. When the child was eight months old, the mother became too weak and ill to care for it, and was sent to hospital. The infant did quite well until ten months old, when she became weak, ran a fever, refused to eat, and lost interest in things.

Physical examination showed impaired resonance in the middle portion of the left lung, suppressed breath sounds, but no râles. The von Pirquet test was strongly positive. After being in the hospital six weeks, she developed all the symptoms of meningitis. Her temperature constantly was 100° to 106°, pulse 160. Spinal fluid was under increased pressure with a cell count of 10 per cu. mm. After meningitis symptoms had been present for two weeks, she died. The diagnosis was confirmed by autopsy. Figure 5 shows a tuberculous consolidation of the middle portion of the left lung.

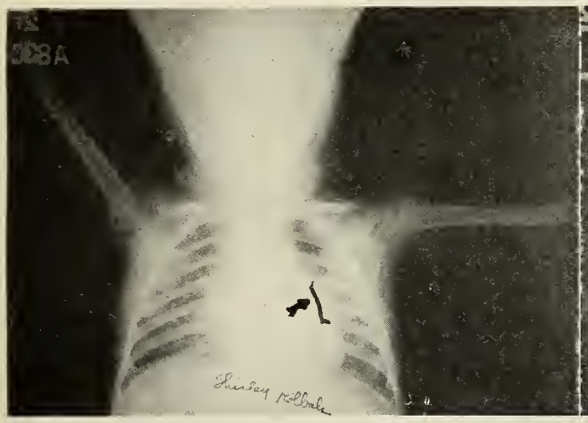

Fig. 5. Tuberculous consolidation—wedge-shaped.

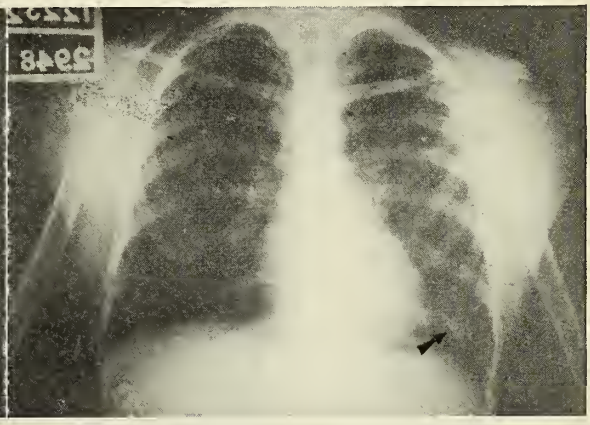

Fig. 6. Focal tuberculous calcified nodule.

Fig. 7. Generalized mottling of miliary tuberculosis.

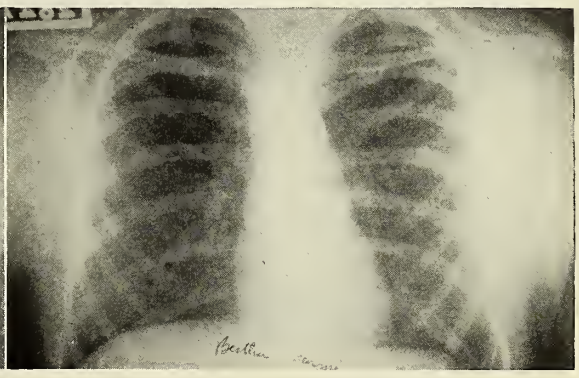

Fig. 8. All mottling has cleared up.

This type of lesion falls into Class C in McPhedran's[5] classification. The prognosis in this type of case is uncertain, usually retrogressive, but in Case 5, tubercle bacilli entered the blood stream and caused tuberculous meningitis.

Case 6.—L. M., a white female, six and a half years of age. The mother died of tuberculosis. Symptoms began in 1929 with a persistent, productive cough, slight fever and pleuritic pains. There was no weight loss. Chest examination showed no change in resonance or breath sounds, but a few coarse râles in the left base. The von Pirquet test was positive. The patient was at Nopeming six months, gained weight and developed normally. Chest examination was negative and there were no symptoms on discharge. Figure 6 shows a calcified nodule in the sixth intercostal space near the left cardiac margin, which makes this case one of Type A of McPhedran's classification.

The prognosis in this type of case is good, except that a caseous non-capsulated focus in an infant is serious. Associated lymph node involvement is recordable if calcified. If caseous, they are recordable only if much enlarged.

Case 7.—B. N., a white female, aged 13, has been at the Sanatorium a year and a half. There was no history of exposure to tuberculosis obtainable. She was well until June, 1928, when she developed a severe, persistent, productive cough, accompanied with fever, anorexia, loss of strength and weight. Fever has never been over 100°. Mantoux 4 plus with .001 mgm. old tuberculin. *X*-ray plates taken July 3, 1928, show a generalized miliary mottling throughout both lungs. A plate taken November 28, 1928, is shown in Figure 7.

Due to the fineness of the mottling and the poor film, the miliary lesions can be seen only with difficulty in the photo, although they are very definite in the *x*-ray film. Figure 8 is another *x*-ray of this patient taken March 11, 1930, which shows no parenchymal pathology and the only abnormality present is possibly a widened hilus area.

striking decrease in the inflammatory reaction in the left hilus area. The circumscribed area of increased density is seen at the level of the clavicle. The last plate, taken February 18, 1930, and shown in Figure 11, shows a normal hilus area with a small calcified opacity just behind the clavicle. The inflammatory shadow in the hilus area was undoubtedly made up of several

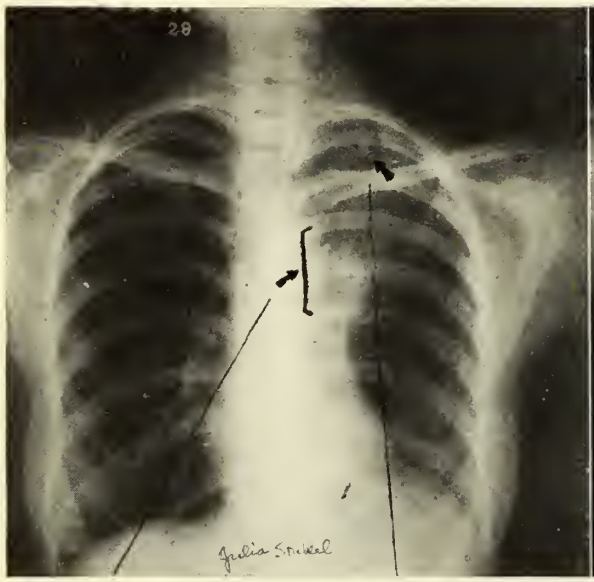

Fig. 9. Calcified lesion (left apex). Inflammatory reaction in left hilus area.

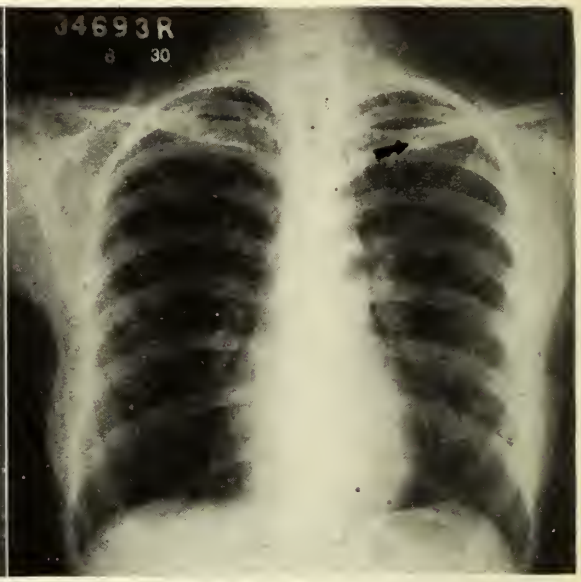

Fig. 10. Calcified lesion.

Recovery in this type of case is extremely rare. In this respect Case 7 is unusual because the patient has at the present time no symptoms and her general condition is good. The intracutaneous test is markedly positive. What future tuberculous trouble this patient will have, would be of great interest to know.

Case 8.—J. S., a white young woman, twenty-four years of age, has been at Nopeming three months There has been no history of exposure to tuberculosis. Symptoms began in September, 1929, with cough, weakness, and loss of weight and strength. Chest examination on November 15, 1929, showed a normal right lung. On the left side there was impaired resonance extending to second rib and the fourth dorsal spine with bronchovesicular breathing but no râles. The sputum was positive for tubercle bacilli. The patient is a strictly bed patient and is doing very well, gaining in weight and symptom-free. The sputum is still positive. The interest in this case lies in the fact that it belongs to the adult type of tuberculosis, but has the usual location of the childhood type. It is also interesting to note that the lesion is clearing up rapidly. Figure 9 shows an inflammatory reaction in the left hilus area with dense lines extending into the apex to a circumscribed area of increased density. This plate was taken November 15, 1929. Figure 10 is another *x*-ray picture taken seven weeks later, which shows a

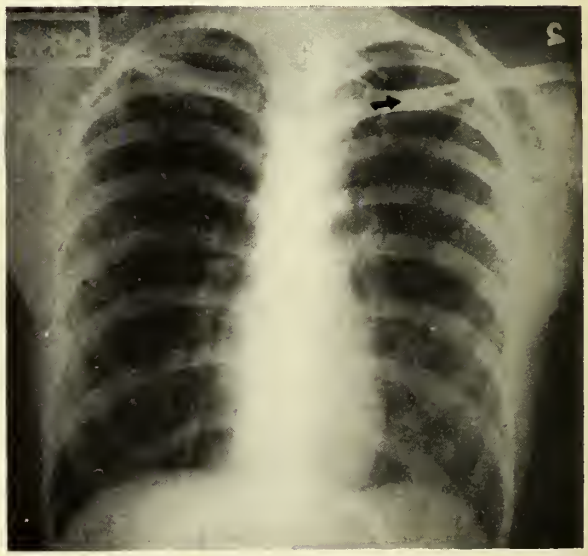

Fig. 11. Calcified lesion.

enlarged tracheo-bronchial lymph nodes together with an inflammatory exudate in the adjacent parenchyma.

This is a case of reinfection because a ghon tubercle is seen in the apex which is the primary lesion. This case illustrates what can be done towards the healing of a reinfection type of tuberculosis if diagnosed and treated early.

The prognosis in such cases is dangerous if the lesion is multiple and occurs in a child. In this case the prognosis is excellent.

In conclusion, it may be of value to state the basis upon which the diagnosis is made: History, symptoms, physical signs, Mantoux test, *x*-ray evidence, and exclusion of other conditions, which may produce similar symptoms.

This paper is offered as illustrative and confirmatory evidence of the work of the authors previously mentioned.

Years ago, Gustave Le Bon wrote a small classic called "The Crowd," a study of the popular mind, in which he held that a crowd cannot be compared to the individuals that make it possible; that the mean average is probably of little value, as the new character of a crowd takes on new features and the new average is below that of the mean. One learns from Le Bon that a wide chasm may separate a great surgeon from an orderly and yet, as to character, the more lowly one may be the better of the two; that men seem to take to the primitive in the mass; and that crowds may be composed of units spread out over a wide territory held together by a common emotion. All this helps in trying to understand medical assemblages. Doctors in their home environment may be individually men of great judgment and keen to see the dangers of the future. When brought together in the mass, however, they seem to take on rather childlike qualities, as may be seen by their restlessness, tendencies to run in and out, irritation over some mechanical error, and above all their opposition to an address pointing out to them the weaknesses in their nonprofessional outlook. Under the spell of a celebrated speaker or a well known personage, I can think of no audience more quickly led than that of a group of medical men. This was illustrated the other day at Detroit when the powers of the Interstate Post-Graduate Assembly conferred on Henry Ford the honorary title of Doctor before an audience of nearly 5,000 physicians. The crowd went wild and clapped its hands and shouted in childish enthusiasm. Mr. Ford stood smiling amidst a number of celebrated medical men while Dr. Deaver, his picturesque personality all aglow, delivered the bestowal address. The industrialist said not a word, but bowed and retired from the scene, as a mighty roar of approval followed. This idea is covered in Gustave Le Bon's book. Had any member, prominent or obscure, of that august gathering arisen and told this shouting crowd that they were about to award a great honor to one who had lately criticized their whole profession rather harshly in a series of syndicated articles, written on decidedly slender knowledge, and that in Detroit he had built a hospital to controvert directly the medical profession's idea of how a hospital should be run and that in the medical fraternity in his city there was more than one doctor who felt decidedly hostile to his attitude—that member would have been summarily dealt with.

Mr. Ford is a great inventor who made a good car that has carried many a doctor efficiently to his destination. I doubt if Mr. Ford ever constructed his car as a benevolent gesture. But I should like to ask if Behring would not have been a millionaire if he had patented diphtheria serum? Would not Roentgen have been more of a Croesus than Ford if he had received $20 on all *x*-ray outfits and a royalty on the plates? Where would the man be who invented the vaginal speculum if he had patented it? What about Banting and a cent on every unit of insulin? Any one of these men could be where Ford is if he had said he chose to run that way. Always we overlook our own great discoverers.—Hall, Harry M.: Descartes was right. A. M. Assoc. Bull., 24:233.

OCULAR MANIFESTATIONS OF HYSTERIA IN CHILDREN*

John M. Robinson, M.D.
Duluth, Minnesota

A TEN year old boy whose sister had recently returned from a school for the blind suddenly lost the sight in one eye. When examined a fortnight later the vision of the right was normal while with the left eye he counted fingers only at a distance of two feet. A girl of twelve was shaken up in an automobile accident in which her father was killed. A month later she appeared complaining of poor sight. The vision of each eye was less than 20/200. In both of these patients the objective findings were entirely negative; the functional tests suggested psychic disturbance, and complete recovery eventually occurred in both children. Similar instances are not wanting in biblical literature; in our daily press similar recoveries are still occasionally chronicled under the miraculous.

Now differing not in kind, but in degree only, are the numerous complaints emanating from children, seven to fourteen years of age, a period to which this discussion is largely limited, of blurring and misty sight with the vision by the test chart ranging from 20/30 to 20/70.

Brandenwell Carter, after an extended survey, wrote, "The fact with which I have been most impressed is the existence in London of the very large number of children with subnormal vision, for which their errors of refraction were insufficient to account." In this connection Kerr[1] refers to an examination made by him of 330 healthy boys, in which group seven were found with vision of only 20/50 or thereabout, and with nothing to explain the deficiency, but in all of whom full recovery occurred within a few months without treatment. Wilson[2] located an epidemic of nine or ten such cases which he ascribed to under-feeding, poor housing and post-war depression. Katz[3] says that 4 per cent of Russian children exhibit at one time or another these visual peculiarities. In health and mental balance the children of Minnesota probably equal any in the world, yet from a recent survey of fifteen thousand the writer ventures the opinion that this particular manifestation of the ancient neurosis is nearly as common with us as Katz found it to be in Russia.

In reviewing my records of 250 consecutive refraction cases in children, completed under atropin, hysteria, or more elegantly expressed psychic amblyopia, was found to be the major element of the disturbance in ten. In this group there were nine girls and one boy. All appeared to be well nourished; four complained of headache, one of lacrimation, and two of photophobia. All of them could read fine print (J.2 or 3), but all of them balked at the smaller letters on the test chart. In none of this group were the refractive errors conspicuous, and the correction of such small errors as did exist failed to produce normal vision. The mental attitude was that of indifference and unconcern. Two of the children were sotto-voiced; one girl was said to talk continually in her sleep, and two exhibited that definite evidence of hysteria—monocular diplopia.

This slight degree of amblyopia in which the complaint is blurring of distant objects, with the visual tests showing 20/30 to 20/50, is, as a manifestation of hysteria, more common in children than in adults; and the other ocular stigmata also, I think, predominate in children. Those transient attacks of blurring which are complained of while reading, supposed failures of accommodation, are put down as hysteric by many observers; and into this same diagnostic dustpan Dr. Casey Wood[4] sweeps children's complains of photophobia, lacrimation, and the winking habit. Perpetual frowning and scowling may be mild forms of hysteric contractures. The cramp of the ciliary muscle which produces a false myopia probably comes in this same category. On the other hand, anesthesia of the conjunctiva and cornea, and the severe blepharospasm, mentioned by Burch[5] as occurring in adults, are symptoms not as often seen in the border-line type of hysteria of late childhood. At this age, however, comes into prominence the arch-symptom, monocular diplopia or polyopia—an object doubled, tripled or even quadrupled with one eye closed; and excepting a few pathological rarities, this phenomenon, when it does

*Read before the St. Louis County Medical Society, Duluth, May 8, 1930.

occur, may be said to be pathognomonic of the neurosis. A girl of ten complained of blurring and the doubling of objects. With one eye closed she reported a yellow pencil as "two." A red pencil was now substituted and the diplopia disappeared, but back again to the yellow one, and the pencil was seen as two. These double images of hysteria play curious tricks, but usually they can be differentiated from the diplopias which result from true paralysis. When this interesting symptom is absent in children, the diagnosis of hysteria is largely a matter of assumption, based on the negative objective findings, combined with the type of the complaint and the mental attitude of the complainer. At least, this is true until one reaches the visual fields, and here the diagnosis may usually be stabilized.

For the purpose of mapping the field of vision, and especially for studying changes in the periphery, the perimeter remains the apparatus of choice. It will be recalled that in the four principal meridians the field extends about 55 degrees upward, 70 downward, 65 to the nasal, and 90 degrees or slightly more in the temporal direction. In hysteria, more or less contraction is found in the great majority of cases. A narrowing of even 5 or 10 degrees in the upward, downward and nasal direction, and 15 degrees in the temporal line should give rise to suspicion. If the contraction is a little more than this, and the eye-ground clear, brain disease reasonably excluded, and alcohol, nicotine, quinine and such poisons not in question, then hysteria is very likely at work. When the test object is reported at an equal distance around the fixation point, and can be seen only within the 40 or 50 degree circle, we have the classic, concentric contraction. Parker[6] found this celebrated text-book symptom in nine out of fifty subjects whose hysterical manifestations varied from aphasia to vomiting; while thirty-two of his fifty cases showed slight, although definite, contraction which was not, however, of the concentric type.

A number of years ago, Bjerrum, a Dutch ophthalmologist, discarding the perimeter painted his consulting room door black, against which surface he studied the fields of his patients. Since that time the so-called tangent screen or campimeter has come more and more into general use. For particularly accurate work a black screen 1.5 or 2 meters square, with degree circles marked on the surface, is to be preferred; but for preliminary and tentative studies a well cleaned blackboard, evenly and thoroughly illuminated, serves as a most convenient substitute.

The height of the average blackboard requires a working distance of 0.5 meter. To assist in holding the attention some small object such as a gold star or cross is placed opposite the one exposed eye, and around this fixation point may be drawn faintly dotted circles with radii of 6, 14, 25, 40 and 62.5 cm., which correspond respectively to 10, 20, 30, 40 and 50 degrees on the perimeter. Beyond the last mentioned distance, however, the field on the screen cannot be expressed in degrees without geometric computation.[8] In the absence of these degree circles on the blackboard it will be noted that a 2 cm. white test object, held on the tip of a black pointer, will be detected in the four principal meridians, about 60 cm. upward, 70 to the nasal side, 80 downward and 110 cm., or slightly more, to the temporal side. If the object is not reported within 10 cm. of these distances, a slight contraction is present which may call for closer study or mapping on the perimeter. If the field is contracted to 50 degrees in all directions, as it is in many hysteric cases, then the blackboard is as satisfactory for the purpose of studying the case as any tangent screen. Accuracy requires fixation of the head, one eye comfortably closed, even distribution of light (5 to 7 foot-candles), fresh test objects; and a slight allowance made for myopia, long lashes, deeply set eyes, etc. In addition to these contractions of the visual field which occur in hysteria, there are other phenomena which the simple blackboard will disclose:

1. Normally the field is somewhat widened with the enlargement of the test object, and more especially if the subject is moved further back. In hysteria this does not occur to the same extent, if at all, and the field is then described as "tubular"—a condition necessarily of functional origin.

2. With the normal subject there is an area of uncertainty as the test object is moved back and forth over the edge of the field. In hysteria the patient is likely to be more prompt and positive in reporting the appearance and disappearance of the object, which may be seen as coming in "bit by bit," or "just half in sight," if a large test object, such as a piece of writing

paper, is used:[7] thus, the field is sharply demarcated.

3. The "predilection for red," stressed as a characteristic of hysteria, shows itself frequently as a fully normal or slightly exaggerated field for that color, while the form or white field is considerably contracted. In this connection, girls, who are rarely color blind, may be found confusing various shades which under normal circumstances they would readily distinguish.

4. Foerster's displacement phenomenon depends on the fact that the appearance of an object within the field exerts a greater stimulation than its disappearance. If an object is moved from the extreme temporal side it may be perceived at 90 degrees, when moved across the center it may disappear at 35 degrees on the nasal side while it should be seen as far as 60 degrees. This is an occasional happening in hysteria.

5. Color field interlacing and reversals are too complicated and time-consuming for young subjects in whom this game of hysteria hunting may well be limited to five minutes at a sitting.

It is not only those who show eye symptoms who exhibit the fields of hysteria; these peculiarities are quite as likely to be present when the complaint is referred to some point as far from the orbit as the tip of the spine or the "pit of the stomach." As an experimental control I tested fifty uncomplaining and healthy appearing children of average intelligence, from eight to twelve years of age. Forty-four showed full, normal fields; four were slightly contracted—faulty attention and appreciation; one boy, generally inaccurate; one girl, probably unsuspected hysteria. For the purpose of comparison I then tested fifty of the same age period, all of whom had been passed as having no obvious physical defects, but who were given to complaining of headache, side-ache, fugitive pains in various localities, vertigo and so on. In this group of complainers, twenty-two showed more or less field contraction: ten moderate narrowing; twelve concentric contraction, and in other respects the fields were definitely of the hysteric type. Also, in the group of ten young amblyopes previously referred to, eight showed definitely contracted fields. The boy mentioned in the introduction of this paper had a narrow and tubular field on the right, on which side he did not allege blindness, and the girl of the automobile accident had fields confined to the 20 degree circle.

Pierre Janet[9] defined hysteria as "a form of mental depression characterized by retraction of the field of consciousness, and a tendency to dissociation, etc." This limitation of consciousness is comparable to the contraction of the visual field, which is, indeed, part and parcel of the general inhibitory process. The hysterical subject according to this view is incapable of taking into the field of consciousness all of the impressions which the normal individual is aware of; and it is this failure which can be so easily demonstrated, and to some extent measured, on the ordinary blackboard. Charcot[10] first stressed the frequency of cutaneous anesthesia in hysteria, although the neurologists now say that this is not as frequent an occurrence as the French master originally insisted. These visual field contractions, with their concentric form and abrupt edges, are again comparable to the curious anesthetic areas of geometric pattern and sharp outline found on the surface of the body. In medieval days, and even on into the eighteenth century, adepts in the art of locating these spots with lost sensation were professionally employed in testing the epidermis and mucous membranes of those suspected of being satanically possessed. Could the "tester" outline the claw of the Devil, or any anesthetic area resembling it, it was all up with the unfortunate suspect. Well was it for the witches that the tangent screen was not in use in those days.

The matter under discussion has been limited to preadolescents because they have been available for group study; partly, too, since they are less subject to the border-line neuroses, and partly since behind their complaints there is less likelihood of organic disturbance. Moreover, the mind of a child, from seven to fourteen, corresponds to the period of psychological development of ancient and medieval people, among whom, from all accounts, hysteria was highly prevalent. Also does this affection turn more to the eyes than formerly, with the increasing number of ophthalmologists, the glittering advertisements of optometrists, and the increase of schoolbooks, school nurses and test charts. Hysteria, too, changes its fashions: there are now fewer witches and fewer bewitched; the phantom

tumor is not as frequent as it was thirty years ago; the nail of Sydenham[15] has been replaced by tenderness in McBurney's point; globus hystericus is somewhat replaced by those undetectable foreign bodies in the throat, the search for which so wearies the laryngologist. From fourteen to nineteen may have been the preëminent half decade for hysteric exhibitions in the reign of Queen Victoria when girls of that age were more tightly dressed and more socially suppressed than at present, and had less opportunity to let loose their emotions. Even somnambulism is less heard of since young ladies have taken to pajamas. The age of hysteric preference may have moved down from sophisticated sixteen to the more simple minded year of eleven. Today, also, not only are the eyes more frequently involved than formerly, but the Devil's claw has recently reached into the paranasal sinuses. A few days ago a child appeared saying she had "sinus trouble"; no careful study of the nose had been made, and no *x*-ray pictures taken, but she did exhibit a sharply contracted visual field.

CASE REPORTS

Case 1.—Hilma K., aged 9, Finnish. Complaint: Indistinctness of the writing on the blackboard, and the fading away of the features of her teacher (the child had been recently separated from her parents and farmed out). Appearance: Healthy, well nourished. Demeanor: Passive. Vision each eye 20/40. Reads fine print (J.2) without difficulty. The fields are concentrically contracted, of tubular type, and the test object is reported with alacrity as it passes over the edge—and this in contrast to the rather slow responses which are given to other tests. One month later refraction under atropin showed hyperopia 1 diopter, and a trace of astigmatism. Vision not improved with any correction.

Case 2.—Viola B., eight and a half years old, Italian. Complaint: Blurring of objects in the school room; lacrimation, photophobia. Vision 20/40. Fields limited to 40 degrees in all meridians. Refraction under atropin: Hyperopia, as in Case 1, with a half diopter of astigmatism. No improvement of vision with any correction.

The glasses with which these children were provided were soon discarded when some weeks later the vision became normal and their eye troubles had been forgotten.

Hyperopia of one diopter and a small degree of astigmatism occurs in 50 to 60 per cent of the children of this age.[12] Whatever change takes place in the refractive error is slow and is not materially influenced by the wearing of glasses. A group of sixty children were observed who had had such weak plus corrections ordered. Forty-eight of these children were persistently forgetting to wear their glasses. "Eye strain" in childhood is a bogey to be regarded with some suspicion. "Asthenopia, meaning weakness of vision, is a functional condition more common in early adult life than in children." (Kerr.) "The retina does not get tired and refuse to function; variations in response are due to variations in central rather than retinal function, and the terms retinal fatigue and retinal asthenopia have probably a much more restricted significance than is usually attributed to them." (Traquair.)

Case 3.—Louise F., aged 12, had had a bad cold in February. In the month of April, after a quiet interval of six weeks, she begins to cough daily about 2:00 p. m. and keeps it up until school is out. The cough is non-productive; pulse and temperature normal; chest, nose and throat negative; but the visual fields are typical of hysteria.

Case 4.—Mary D., aged 11. The complaint is that of recurrent pain in the right side. Physical examination has given negative results; fatigue, diet and posture have been considered. The only positive finding is a visual field limited to 40 degrees, and tubular in type.

Case 5.—Ellen S., aged 11. Healthy in appearance, slightly underweight, she has few complaints. The pulse rate while standing was found to be 120, and after 10 minutes in the recumbent position 106. Temperature normal; recent history and physical examination negative. No coffee; no evidence of mental excitement. The visual fields were similar to those mentioned above. The pulse rate five days later was 104 while resting, and the fields were still contracted: hysteric tachycardia (?).

Case 6.—Alice H., aged 13. Slightly anemic; growing rapidly; mild fatigue symptoms. Pulse 105 while resting; distinct tremor of the extended fingers and a fibrillary tremor of the tongue. There is a suggestion of an exophthalmos and an enlarged thyroid of the type and size found in 20 per cent of the girls in this locality. The central vision is normal, but the fields contracted, tubular, and very sharply defined. This girl reported to be very nervous, appears to be taciturn and unconcerned. Six months later the tremor had quieted down, the pulse slowed, and the visual fields were back to normal.

Case 7.—Ellen F., aged 14. Referred for examination of the eyes because of difficulty with reading and "terrible headaches." There was no manifest refractive error; muscle balance, accommodation and vision were apparently normal. The headaches, the location and periodicity of which she was very vague about, dated from an appendicitis operation fourteen months before. She also stated that her doctor had given her pills which had caused the trouble with her eyes. The fields were typical of hysteria.

This same story of an appendicitis operation

followed by persistent headaches I have heard from two other girls who showed hysteric fields, and in whom there was no pronounced refractive error, and little else to account for the complaint.

Case 8.—Margaret S., aged 18. This girl had been admitted to the hospital with a diagnosis of appendicitis made by one physician, and of pelvic abscess by another. I was asked casually by the surgeon-in-charge to see this patient who alleged great tenderness in the lower right abdomen and exhibited rigidity of the abdominal wall. The temperature and pulse were normal. A day or two later on with an improvised screen, the visual fields were found moderately contracted—about 20 degrees. The complaint of abdominal tenderness, however, being persisted in, an exploratory operation was performed: appendix normal; no abscess found; recovery rapid.

Case 9.—John H., aged 13. Long legged and slow brained; in an opportunity class with children several years his junior. The boy was eager to get away from school and work on a freight boat. There had been some complaint of poor sight, but the vision reached 20/20 after coaxing; the fields, however, were those of hysteria, and that he was reporting with a fair degree of accuracy was evidenced by the rapidity with which he located and outlined the blind spot; a proof of concentration and observation which is entitled to a position among the mental tests, but not yet included in the text-books.

Case 10.—E. H. A highly intelligent boy of 20; an only child, constantly attended by one or both parents. He has stammered, moderately and intermittently, since early boyhood, and has been much examined with negative results. Recently a pronounced tremor of the fingers has developed, and the handwriting begins to show irregularity; there is a scanning type of speech. The visual field shows a slight shortage in the upper nasal quadrants, and extends only to 75, in place of the normal 90 degrees, in the temporal line. This supports the suggestion of disseminated sclerosis, but fortunately may belong to the more common affection.

The pathology of hysterical amblyopia has its seat neither in the eye or the visual pathway to the occipital lobes nor in those receiving stations, but, it is suggested, in the fibres which run from thence to the higher intellectual centers where "the synapses at one or more of the cell stations in the path to the cerebral cortex must become unswitched, probably as the result of the retraction of the dendrons";[11] thus, the going wrong of a localized process which is somewhat akin to the widespread cerebral working which results in natural sleep. The result is a failure in the function of response to that which is properly registered in the brain; a fault, if you will, in the starter! On another occasion in the same type of brain certain inhibitory fibers fail—the brakes won't work—sobbing, laughing, hiccoughing, naturally excited, unnaturally persist, and we are confronted not with blindness, deafness and such, but with "hysterics."

As a diagnosis "hysteria" is unpopular, both from the standpoint of patient and physician; to the one the word implies a weak mind and a suspicion of prevarication; to the other it is an indefinite affection, and one as yet not clearly defined. For the oculist the word hysteropia, an invention of Dr. Casey Wood, is a convenient refuge. Hysteria, however, must be admitted to be a clinical entity, although one which, unless we possess the superknowledge of the psychoneurologists, we are prone to confuse with the other neuroses and psychoses which Freud and others have so striven to teach us to separate and distinguish. It is neither imagination gone rioting nor malingering. It is not merely the result of suggestion, although those afflicted with hysteria are most easily led by that process. The idea of a defense reaction continually suggests itself; children are most frequently affected in school-time; adults thus react to "an intolerable situation." Our most remote ancestors probably utilized the trick (now referred to as a neurosis) to save themselves from assaults of their enemies, as do molested spiders and the proverbial opossum. All of this relates to but does not define hysteria, which Mobius, Janet, Babinski, Freud[14] and forty others have attempted with more or less disagreement. Plato[13] himself planted the misnomer in a poetical definition; and this idea about the uterus lasted from 400 B. C. until about 1750 A. D. when the disease was discovered in the male of the species by one Raulin,[9] a Frenchman, who may have gotten his idea of masculine participation from Sydenham[15] who was, indeed, antedated in this by Shakespeare.[16] All medical Europe was racked for a while over this heresy to a long cherished belief, which may come again into its own when we find that hysteria is due to the curdling of the ovarian hormone, or the accidental precipitation of its analogue in the male.

The question here is not just what hysteria is, nor by what method the affliction is to be relieved, for those are the problems of psychoneurology; but how shall it be told, and to what extent does it mix in and complicate the already somewhat discredited science of symptomatology? It is common in those of childish mind from eight to forty-eight and on; its minor

exhibitions are especially frequent in preadolescence. If in one of these young subjects one eye alone sees double, or the visual field is concentrically, or otherwise contracted, it is a four to one venture that the patient in her (or his) complaint is mimicking, magnifying or prevaricating, and the last—without any reflection on the moral aspect—to such an extent that the substitution of the name prevaricosis multiforme might not be out of place.

VALVULAR HEART DISEASE IN YOUNG ADULTS*

C. A. McKinlay, M.D.
Minneapolis

THE observations noted in this paper are from 67 cases, chiefly University students, who were given entrance and subsequent physical examinations which revealed valvular heart defects. These examinations were done routinely or on account of the presence of cardiac murmurs, tachycardia, palpitation or anxiety regarding suspected heart trouble. The cases then were selected, from a large group ranging as to age from 15 to 35 years with an average of 20 years, and as to sex, 47 males and 20 females, from a student body in which males predominate approximately 2 to 1. It is a selected group also in that they were individuals without cardiac decompensation; as a rule they had suffered little or no inconvenience from their condition and they may, therefore, be considered in the heyday of life as far as cardiovascular efficiency is concerned. Only 17, or about one-fourth of the group, had noted dyspnea.

An attempt has been made to use critical judgment in the diagnosis of the type of lesion. The clinical picture presented by the group with aortic insufficiency has been as clear as any known. A diastolic murmur beginning early and heard best at the left sternal border, associated with water-hammer pulse, has been considered pathognomonic of aortic insufficiency. Often capillary pulse and Duroziez sign were demonstrable. Similar peripheral vascular signs with increased pulse pressure present in hyperactive hearts, notably in hyperthyroidism, were of course not considered significant. On the other hand, hardly any single pathognomonic sign of mitral involvement in the absence of demonstrable pulmonary congestion was known, although, in mitral stenosis, diastolic murmur at or near the apex has been emphasized and, with bulging in the area of the pulmonary conus, has been considered pathognomonic. A check of clinical diagnosis with necropsy findings has shown, according to Cabot (1), that mitral stenosis of all valvular lesions has been most frequently overlooked; that in a series there were 107 solitary lesions of the mitral valve compared to 28 of the aortic, and that 25 of the 28 were in men. Dr. E. T. Bell[2] states that in a series of about 460 necropsies which revealed valvular defects of rheumatic origin over 50 per cent had involvement of the aortic valve, usually combined, and that solitary lesions of the mitral valve were about three times as common as defects of the aortic valve. Such usual pathological findings would indicate that, in the group reported clinically recognized as having solitary aortic lesions, the mitral involvement may have been occasionally unrecognized.

Paul D. White,[3] in Cecil's textbook, classifies the types of valvular lesions as follows: 100 mitral, 50 aortic, 25 tricuspid, and pulmonic one or less. Willius[4] found, in a series of 170 cases, 78 per cent of mitral, 13 per cent of aortic, and 15 per cent combined. In a recent report, B. A. Schwartz[5] in 55 cases of valvular disease, 40 under 11 years of age, found 51 of mitral involvement, 3 aortic, and one combined. The impression gained from this last observation is not supported in the series here reported, where there is a relatively higher percentage of aortic involvement. It is thought that an inadequate impression of the incidence of involvement of the aortic valve in rheumatic infection has prevailed, fostered in part by certain texts which have not recorded series of cases.

In the 67 cases reported, 22, or approximately one-third, were classified as mitral stenosis and insufficiency, 18 as mitral insufficiency, 20 as aortic insufficiency, 2 aortic stenosis, 4 aortic insufficiency combined with mitral stenosis and insufficiency, 1 aortic insufficiency and stenosis combined with mitral insufficiency; 27 cases, or 40 per cent, had aortic involvement alone or combined. In aortic cases, solitary and combined, males predominated 22 to 5, while in mitral they predominated only 25 to 15.

*From the Students' Health Service, University of Minnesota. Presented before the Minnesota Society of Internal Medicine, Duluth, Minnesota, May 26, 1930.

Outline of the heart upon six-foot plates and by orthodiagram more recently was obtained in 33 cases and bulging in the region of the pulmonary conus aided in establishing the diagnoses in 10 of 17 mitral cases, and increase in the left ventricle in 7 of 13 aortic cases. The others did not show change considered to be above possible normal limits. In the group studied, inability to demonstrate in certain cases change of cardiac outline by *x*-ray calls attention, first, to the fact that with perfect compensation there may be very minimal change actually present; and, second, to detect minimal changes the *x*-ray interpretation of cardiac outline should be made in view of the individual's height and weight and that more frequent examination of the retrocardiac space by esophagram be made.

The detection of cases largely silent as to usual cardiac symptoms is illustrated by K. R., aged 20, engaged in active athletics, wrestling, who appeared for examination on account of moderate sleeplessness. Physical examination revealed aortic insufficiency without preceding infections except occasional sore throats and without recognized change in cardiac outline on the six-foot plate. He was advised to guard against cardiac overload and to have tonsil tags removed. Four years later a fatal illness supervened and necropsy showed subacute bacterial endocarditis and the old fused aortic valve defect. Another case in the series with aortic defect is known to have succumbed to subacute bacterial endocarditis.

Seventy-one per cent gave a history of rheumatic fever or chorea 1 to 15 years previous to observation, with an average of 7.4 years, which would make the average initial attack at 12.5 years of age. The incidence was essentially identical in individuals with mitral involvement and in those with aortic alone or combined. Approximately one-third, or 31 per cent, of those with rheumatic fever had recurrent attacks. Lues was not found in any case. Electrocardiographic study was not available in a majority of instances.

As a control, a record was made from 100 histories in normal males of similar age regarding the incidence of rheumatic fever and tonsillar infection and removal. Two gave a history of rheumatic fever; 27 gave a history of tonsilitis; 36 had normal appearing tonsils; 42 had had tonsillectomy; and 22 had infected appearing tonsils.

Approximately one-half, or 36, gave a history of frequent sore throats, tonsillitis or quinsy. Nine out of 19 cases without rheumatic fever gave a history of attacks of tonsillitis and only 2 without a history of rheumatic fever or tonsillitis had scarlet fever alone. There were 17 instances of both scarlet fever and rheumatic fever or tonsillitis. Scarlet fever alone did not appear to be an important precursor.

While there was the usual expected frequency of history of rheumatic fever, an appreciable number (15 per cent) have remembered no significant throat infection or joint or muscle pains in childhood. Thirty-five, or slightly over half of the group, had had tonsils removed with a clean result; 15 had tags remaining, and 14 had not had tonsillectomy. Several had had tonsillectomy two or more times. The possible malevolence of tonsil tags in this relationship is illustrated by G. F., male, age 21, college athlete, who gave a history of tonsillectomy in childhood. In December, 1929, he developed tonsillitis, followed two weeks later by rheumatic fever with subsequent development of signs of mitral insufficiency which were not present at the time of previous examination. Delayed complete tonsillectomy was done and the door was locked after the horse was stolen. Not infrequently tonsillitis in small tags has been noted with marked systemic reaction.

Although it is realized, as stated by Swift,[6] that available statistics do not show any great advantage in tonsillectomy from either a prophylactic or curative standpoint with regard to rheumatic fever, figures at present are too meager for final judgment. Farnum,[7] in a report concerning the effect of tonsillectomy upon existing cardiac disease in 526 adults, chiefly with valvular defects, concludes that if tonsillectomy is to be used in the future as a definite therapeutic measure its best results will be obtained before the incidence of heart infection or very early in its course; and that the removal of tonsils certainly will not guarantee a halt in the progress of existing cardiac disease, because the cause of such infection may still be present in the throat or elsewhere in the body.

Gordon[8] expresses a common attitude that the tonsils may be considered guilty until proved in-

nocent; that rheumatic fever may develop after satisfactory enucleation, but that such attacks are milder and cardiac damage less pronounced. A continued minimal fever after acute tonsillitis without rheumatic fever, as occasionally seen, cannot help but impress the clinician with its significance as a cause of carditis when associated with signs of valvulitis. Illustrative is M. B., female, aged 21, who had acute follicular tonsillitis with marked systemic reaction and with minimal fever and tachycardia continuing for about eight weeks without tuberculosis or other demonstrable infection. Carditis may have occurred and, although positive proof was lacking, the development of systolic murmur and tachycardia was suggestive. In this series no history of the first attack of rheumatic fever occurring after clean tonsillectomy was obtained. Even if allergic phenomena, as emphasized by Swift, are of importance, nodes of primary infection will always challenge interest.

Again, thinking in terms of sore throat and rheumatic infection, even in those who have had all their tonsillar tissue removed there has occurred not rarely a so-called follicular pharyngitis in which patchy exudate, edema and injection involve the lymphoid tissue of the pharynx instead of the lymphoid tissue known as the tonsil, with as severe systemic reaction as in tonsillitis. In the student group, the frequency is striking with which this type of pharyngitis has occurred with marked systemic reaction in individuals either with or without tonsils. The local and general reactions are similar to tonsillitis and there is no good reason to postulate any other type of bacteria as causative. Granted that the lymphoid tissue of the pharynx does not present the opportunity for chronic infection and formation of pus pockets as do the tonsils, situated in their restricting fossa, it is nevertheless the frequent seat of an apparently primary acute infection which may be significant as regards rheumatic fever and carditis, and persisting hypertrophy suggests chronic infection. Small[9] believes that the organism of rheumatic fever prefers the superficial sites in the pharynx and describes, in that disease, a reddening of the anterior pharyngeal pillars extending upward toward the uvula, without ulceration or exudate, coinciding possibly with the rheumatic throat of the older clinicians. Nasal and dental infections are, of course, factors which participate in the infection and hypertrophy of the lymphoid tissue of the throat and must be considered in treatment. In addition, other less obvious portals such as the gastrointestinal tract have been suggested. The not infrequent occurrence of subacute bacterial endocarditis, possibly due to the same organism as rheumatic fever, should emphasize the importance of reducing predisposing tonsillar, oral or nasal infection. If it is avoided, the other horn of the dilemma, decompensation, may possibly be indefinitely delayed, granted that physical overload can be consistently reduced or that the lesion is minimal. The management of the group as above illustrated, resolved itself, in the main, into reduction of physical overload, the avoidance of dyspnea and also invalidism, and the promotion of physical fitness as contributing to increased resistance to infections.

While recognizing that the problem of rheumatic fever has its roots deep in fields that include epidemiology, immunology, and bacteriology, from the clinical standpoint insufficient emphasis has been placed upon the importance of complete tonsillectomy, also upon the importance of pharyngitis and the methods of ridding the body of such infection. Williams[10] and others have advocated the use of radium in the treatment not only of pharyngitis but also of tonsillitis, acute or chronic.

In an attempt to determine whether and how often acute follicular tonsillitis is accompanied by bacteremia, Dr. B. J. Clawson has consented to examine the blood cultures taken during the active state of acute follicular tonsillitis. So far no positive cultures have been obtained.

SUMMARY

1. The good functional capacity of most individuals in the series was noted.

2. The relatively high incidence of aortic insufficiency was noted in a series of cases. This corresponds well with actual pathological findings referred to.

3. Clean tonsillectomy had been done in only about one-half of the cases.

4. The frequency of hypertrophic and follicular pharyngitis is discussed in view of pos-

sible significance in relation to rheumatic fever, the methods of treatment, and prevention.

THERAPY WITH OVARIAN PREPARATIONS

The Council on Pharmacy and Chemistry sponsors the following statement on therapy with ovarian preparations in the current (1930) edition of New and Non-official Remedies: "Rational as ovarian therapy may theoretically appear to be in some conditions, the actual results are rarely striking, and often nil to the careful observer. It is altogether probable that the activity which may be presented by the fresh gland is not contained in a finished desiccated product, or else, when given by mouth, it is destroyed by the digestive juices; extensive clinical experience has failed to establish the value of desiccated preparations administered orally. There is considerable evidence that the aqueous extracts prepared for hypodermic use are inert . . . much work has been done toward the elaboration of a potent, standardized preparation of the ovary, and as a result of these investigations such potent standardized preparations for use by subcutaneous injection have become available. These preparations have been shown to induce estrus in mature animals and to induce sexual maturity in immature animals. Somewhat limited clinical evidence indicates their probable value in ovarian hypofunction." The Council has omitted all desiccated ovary preparations for oral administration on the ground that there is no adequate evidence for their value and, so far, has not accepted any ovarian hormone preparation, because the evidence for the value of these was considered inadequate. (Jour. A. M. A., July 5, 1930, p. 64.)

JOHN R. BRINKLEY, QUACK

John R. Brinkley of Milford, Kansas, has for years been quacking it, but having his own so-called hospital, it has been possible for him to keep his own records, so that only by accident do the results of his work become public. The newspaper publicity that has recently been given to Brinkley is beginning to bring to light some of the crudities of his work. Brinkley's "specialty" is the alleged sexual rejuvenation of the male by the (also alleged) implantation of goats' testicles into the human scrotum. Naturally, the deluded individuals who go in for this particular line of medical humbug are not going to complain after they have found that they have been swindled. If Brinkley had been shrewder, he would have confined his quackery to this particular field. More recently, however, he has been going into the treatment (still alleged) of prostate trouble and, naturally, men do not have the same hesitancy about discussing operations for the relief of pathologic conditions of the prostate that they do in talking about sexual rejuvenation. The Kansas City Star, which has been giving its readers a great deal of information about Brinkley's methods, has now published some interesting material from Brinkley victims who throw light on the way in which he uses his radio station to get in touch with persons and how he treats them at his hospital. (Jour. A. M. A., April 26, 1930, p. 1339.)

THE CLINICAL ASPECTS OF SCLEROTIC CHANGES IN THE AORTIC VALVE*

Carl B. Drake, M.D.
Saint Paul

SCLEROTIC changes in the aortic valve consist of connective tissue thickening and commonly of calcification of the valve leaflets. The calcification may be for the most part at the bases of the valves on one or both sides of the leaflets, may prevent complete opening during systole, or may accompany an adherence of the valve leaflets, producing an osseous-like rigidity of the valve. The outstanding result of the sclerosis is a stenosis of the valve, and often there is an accompanying insufficiency.

The pathologists have recently become much interested in this not infrequent autopsy finding. There is no agreement among them as to the etiology of the sclerosis, but there is a growing opinion among them that a senile sclerosis does not explain the picture. Microscopically, the picture is difficult to distinguish from terminal changes in this valve resulting from known previous rheumatic or endocarditic infection. Clawson has failed to find cholesterol in microscopic sections of these sclerosed valves, which is characteristic of senile sclerosis. There are good arguments for accepting either view as to the etiology of the sclerosis.

It is logical to conclude, when at autopsy there is other evidence in the heart of previous rheumatic disease, that the sclerosis is scar tissue healing of an old endocarditis. Clawson, who has collected a series of seventy-five cases of sclerotic aortic valves, tells me that he has found evidence of a fibrous or adhesive pericarditis in 14 per cent of his cases. There was evidence of a previous rheumatic mitral lesion in 29 per cent of these same cases. However, with this complication the age incidence of the patients was lower.

On the other hand, sclerosed aortic valves are most frequently found in elderly individuals, the male predominating. Often the aortic valve is the only valve showing abnormality. There is usually evidence of marked generalized arteriosclerosis, but it is not uncommon to find little or no atheroma of the aorta in these cases. In many instances there is no history of a preceding rheumatic infection nor of previous symptoms suggesting an endocarditic infection. This lack of history does not, of course, rule out a previous infection of this sort for we know that such an infection can involve the endocardium and go undiagnosed due to lack of arthritic or other characteristic manifestations.

The recognition of these sclerotic changes in the aortic valves means the diagnosis of aortic stenosis and often stenosis with regurgitation. The predominant lesion is stenosis. In most cases the stenosis at autopsy is obvious. The determination at autopsy of the presence of an accompanying insufficiency of the valve in many cases may be largely a matter of individual judgment, but in some instances there is no room for doubt that the valve is also a leaky one. Until we have a method of testing the competency of a valve in vivo we cannot always feel sure of the presence or absence of a valve insufficiency. Aortic regurgitation alone on a purely sclerotic basis probably does not exist any more than an aortic stenosis alone on a luetic basis.

The diagnosis of aortic stenosis is often difficult. Cabot states that the direct evidence is rarely sufficient for a diagnosis. Where regurgitation accompanies the stenosis in these sclerosed aortic valves the regurgitation is even more difficult to detect, as the usual signs of aortic regurgitation may be almost entirely absent. However, with the evidence available, both direct and indirect, it does seem that we should be able to diagnose the presence of a sclerotic aortic valve more often than we do.

The following four patients were rather carefully studied, three of them on my service at the Ancker Hospital, and the fourth (case three) was examined by me, but was attended and correctly diagnosed by Dr. A. R. Hall, to whom I am indebted for the privilege of including this report. All four patients came to autopsy.

Case 1.—C. W., a male aged 66, and a laborer, was admitted to the Ancker Hospital April 10, 1927, complaining of dyspnea, anorexia, precordial pain, weakness and cough. His symptoms had begun three years

*Presented before the Minnesota Society of Internal Medicine, Duluth, May 26, 1930.

previous, and he had been confined to his bed eight weeks before admission. He had never had rheumatic fever.

On examination, orthopnea was present and slight cyanosis noted. A tortuous, sclerotic, pulsating vessel was palpable just median to the insertion of the right sterno-mastoid muscle. A broad, but not forceful, apical heart beat was palpable in the fifth interspace 13 cm. (by projection) to the left, and the right border was percussed 4 cm. out. No basal thrill was felt, and there was no increase in the mediastinal dullness. There was a faint systolic murmur heard at the apex transmitted to the left. The pulmonic second sound was accentuated. A harsh systolic murmur was heard over the entire precordium, loudest at the second interspace to the right, but not transmitted into the vessels of the neck. Râles were heard over the lung areas, and there was a hand's-breadth area of flatness at both lung bases posteriorly. The radial pulse was scarcely palpable, but there was a marked sclerosis and calcification of the radial and brachial arteries. The pulse rate ranged from sixty to seventy. The blood pressure was 128/82 and later 160/90. Marked generalized edema with casts and albumin in the urine developed before death June 8, 1927.

At autopsy, the heart measured 16 cm. in diameter, weighed 560 grams, and both ventricles were markedly dilated. The left ventricle was definitely hypertrophied. The mitral, tricuspid and pulmonary valves were normal. The aortic valves were markedly sclerosed and calcified, two of the leaflets being fused for 1.5 cm. along the borders. Irregular calcified nodules were present in both sides of the aortic valve leaflets, more marked in the aortic sides. The aorta was thin and somewhat dilated, and the intima showed no atheroma. The coronary arteries were calcified, but the lumina were not narrowed. The myocardium showed definite areas of scarring, for the most part in the left ventricle. Mural thrombi filled the left auricle and were present at the tip of the left ventricle.

The noteworthy points in this case were: (1) the undoubted existence of aortic stenosis without transmission of the murmurs into the neck, nor the presence of a thrill; (2) in spite of an aortic regurgitation undoubtedly present, blood pressure reading of 128/82 and 160/90; (3) a murmur at the apex transmitted to the left without organic disease of the mitral valve. Either a relative mitral insufficiency was present, or the aortic stenotic murmur was transmitted to the apex and to the left of the apex.

Case 2.—G. McT. a male aged 61, was admitted to the Ancker Hospital January 21, 1929, complaining of shortness of breath, swelling of the ankles, cough, nervousness, and loss of forty pounds in weight. Shortness of breath had begun two years before, and was noticed on walking fast. A slight cough for several years had become more troublesome the past six months. There was no definite history of acute rheumatic arthritis, although fifteen years previous he had had pains in the knees relieved by extraction of teeth.

The patient had a dusky cyanosis. The heart apex was palpable in the fifth interspace 10.5 cm to the left. A systolic murmur was heard at the apex, transmitted to the left, and the pulmonic second sound was slightly accentuated. A different pitched, harsh, systolic murmur was heard over the first and second interspaces on the right, also at the second interspace on the left, and was transmitted into the vessels of the neck, more markedly on the left. The aortic second sound was reduplicated. No thrill nor diastolic murmur was noted. The radial vessels were tortuous and sclerosed, the pulse rather small, and of low tension. A general edema involving the pleural and peritoneal cavities, legs and thighs, and a large liver were present. The pulse ranged from seventy to ninety, but he had been taking digitalis for several weeks before admission. The blood pressure was 120/80. The urine was normal, and the blood Wassermann was negative.

The patient died February 2, 1929, of bronchopneumonia, and at autopsy the heart measured 16 cm. in diameter, and weighed 615 grams. There was a slight thickening of the free margins of the mitral leaflets, but a marked stenosis of the aortic valve due to fibrosis and calcification involving chiefly the ventricular surfaces of the valves. There was mild calcification of the coronaries and the heart muscle was pale.

The presence of a reduplicated second sound at the base in this case is against the presence of an accompanying aortic regurgitation and no mention of the probable existence of a regurgitation was made in the autopsy report. A different pitched apical murmer is not conclusive proof of a mitral regurgitation having been present.

Case 3.—Miss E. E. aged 80, was examined before her admission to the Miller Hospital under the care of Dr. A. R. Hall, on December 12, 1927. Her complaint was general weakness, pallor, and shortness of breath. She had been fairly well until about two months previous, when marked shortness of breath on exertion was noticed, which had been progressive. Swelling of the abdomen had also occurred. She had never had rheumatic fever.

On examination, the patient was markedly dysneic on lying in bed. A marked anemia was present, and a slight cyanosis. The pulse rate on admission was 68, but later ran as high as 120. The heart was enlarged to the anterior axillary line, and there was a diffuse cardiac impulse. No thrill was palpable. A rough systolic murmur was heard over the entire precordium. Moist râles were heard in the chest. The abdomen was distended, but there was no evidence of fluid. There was a slight edema of the ankles.

The blood pressure was 130/82; R. B. C. 2,160,000; hemoglobin 46 per cent. *X*-ray showed a left-sided enlargement with the mitral configuration and no widening of the aortic arch. The electrocardiogram showed a left ventricular preponderance.

Death occurred January 9, 1928. At autopsy the

heart was extended to the left costal margin and weighed 360 grams. The muscle was pale and flabby. The coronaries were patent. The heart valves were normal except the aortic, which was thickened, very rigid, and admitted just the tip of a finger. The valvular thickening was more marked at the base and on the inner surfaces, producing a marked irregularity. The edges of the valves were thin, and contained no calcium deposits. The root of the aorta contained numerous atheromatous patches and some deposits of calcium salts.

The accompanying anemia in this case doubtless accounted for some of the symptoms, and a very definite myocardial weakness. Although the heart was very large, it weighed only 360 grams. The murmur at the apex was apparently the same as that heard at the base.

Case 4.—J. M. L., male, aged 69, was admitted to the Ancker Hospital April 15, 1930, complaining of shortness of breath and a choking sensation of two weeks duration, a general weakness, and a swelling of the feet. His history of shortness of breath on exertion went back at least to the fall of 1928, when he was in the hospital with the same complaint. At that time he was diagnosed hypertension, with the highest blood pressure reading of 124/105, and also had an auricular fibrillation. He had been a laborer all his life, and had not had rheumatism.

The patient was poorly nourished, orthopneic, and somewhat cyanotic. There was a diffuse, heaving, cardiac impulse, and the heart apex was palpable in the sixth interspace 12.5 cm. to the left (projection) and the right border was percussed 5.5 cm. from the midline. The cardiac ryhthm was typical of auricular fibrillation. A blowing, systolic murmur was heard at the apex and transmitted to the axilla, and no second sound was heard. The pulmonic second sound was accentuated at one time. A faint, medium pitched, rasping, systolic murmur was heard over the second interspace both on the left and on the right, and was transmitted to both subclavians and common carotids. No thrill was felt and no diastolic murmur heard. The radial and brachial arteries were tortuous and sclerosed. There was a two-finger dullness at the right lung base, and numerous râles were heard at the left lung base.

The electrocardiogram showed an auricular fibrillation, and a low tension in the Q. R. S. complex (rate 150). The Wassermann was negative. The *x*-ray showed the heart measuring 17.5 cm. in diameter with a left ventricular type of enlargement and evidence of fluid at the right lung base. Blood pressure was 140/100.

Diagnosis: Aortic stenosis (calcification); auricular fibrillation with cardiac decompensation.

The patient improved considerably, but rapidly failed before his sudden demise on May 8, 1930.

At autopsy, the heart weighed 468 grams. The pulmonary tricuspid and mitral leaflets were normal in appearance. There was a definite thickening of the aortic cusps, with calcification most marked near the attachments of the leaflets. The aortic side of all the leaflets showed definite, raised, calcified nodules. A definite stenosis was thought to be present and also a certain degree of insufficiency. The coronary arteries were moderately sclerosed but there was no evidence of occlusion. The myocardium was brownish in color, and there were numerous fine scars present throughout the left ventricle. The root of the aorta showed some calcification but the rest of the aorta was smooth.

The points worth noting in this case were: (1) the absence of the second sound at apex and second interspace on the right suggesting an aortic regurgitation; (2) the faint systolic basal murmur due undoubtedly to the weak left ventricular action.

SUMMARY

1. The four cases reported were all in elderly individuals none of whom had a rheumatic history nor, if we except a slight thickening of the mitral valve in Case 2, a demonstrable lesion in any but the aortic valve.

2. In all four cases, stenosis of the aortic valve was the predominating lesion. A striking feature was the absence of a systolic thrill in any of the cases reported. This was probably due to an insufficient velocity of the blood stream as a result of a weak myocardium.

3. Although the aortic valve was doubtless insufficient in some of the cases reported, no diastolic murmur was heard in any of the cases. This was doubtless due to the accompanying stenosis which prevented an elevation of the systolic blood pressure and thus the pressure and velocity of the return blood flow through the aortic valve was insufficient to produce a murmur.

4. The pulse pressure in all four cases was within normal limits in spite of regurgitation undoubtedly being present in at least some of these cases. The only explanation of this phenomenon is that the greater the stenosis, the less the regurgitation possible, and the regurgitation is not sufficient to noticeably affect the pulse pressure.

5. Systolic murmurs heard over the mitral region and transmitted to the axilla were not due to demonstrable lesions in the mitral valve. While they may have been caused by a relative mitral insufficiency, they were probably the transmission of the murmur produced by the stenosed aortic valve.

6. Atheroma of the aorta was not an outstanding feature in these cases although there was evidence of marked arteriosclerosis elsewhere in every case reported.

CONCLUSIONS

1. Sclerotic changes in the aortic valve are relatively common in elderly individuals, especially in men.

2. Aortic stenosis is the predominating lesion produced by the sclerosis, but in many instances there is also an accompanying aortic insufficiency. The presence of the stenosis obscures the findings usually diagnostic of aortic regurgitation such as diastolic murmur, increased pulse pressure, and Corrigan pulse.

3. A systolic thrill is frequently absent in these cases, probably due to a lessened velocity of the blood stream passing through the aortic valve as a result of a myocardial weakness.

4. The etiology of the sclerotic process is so far undetermined. Rheumatic involvement of the aortic valve alone is supposedly unusual. No explanation can be given why a senile sclerosis should pick out the aortic valves.

5. The diagnosis should be possible with the finding of a harsh systolic murmur of maximum intensity at the second interspace to the right, transmitted into the vessels of the neck, left ventricular hypertrophy, marked arteriosclerosis in the peripheral arteries, and a small, slow pulse. If there is a marked left ventricular dilatation as well as hypertrophy, a faint or absent second sound, the probable coexistence of aortic regurgitation may be assumed even in the absence of a diastolic murmur or an increased pulse pressure.

6. The sclerotic process producing aortic stenosis does not particularly shorten life, is a gradually progressive affair, and the patient usually adapts himself to a definite limitation in the field of his cardiac response.

A BAKER INSTITUTE "DIAGNOSIS."

The history of every quack concern that professes to cure cancer is monotonously alike. The scheme consists in diagnosing every simple skin lesion, no matter how benign, as cancer. Caustics are then applied and a hole eaten in the tissues with inevitable disfigurement and the patient finally sent back home "cured." Of course occasionally the quacks get real cases of malignant disease. Most of these are sent back home in time to avoid the necessity of the "institute" having to sign the death certificate. A recent case is of interest in that the victim showed more intelligence than is frequently displayed and thus saved himself considerable suffering an disfigurement. Mr. I., an Iowa farmer, developed a lesion on the chin that worried him. He went to Muscatine to the Baker Institute where he was "examined." Mr. I. reports that he was told that he had cancer of the chin and would have to pay two hundred and fifty dollars and also sixty dollars a week hospital charges for four to six weeks. The Baker Institute, according to the victim, applied their cancer remedy. Then the young man got to thinking and decided that the Iowa State University was not far away and that they probably knew as much about cancer as Mr. Baker and his "institute." He went to the College of Medicine of the state University of Iowa where the dermatologic department diagnosed the lesion as *Tinea barbæ*. Treatment for ringworm of the beard was instituted and in less than two weeks the young man went home. (Jour. A. M. A., July 26, 1930, p. 285.)

STATUS OF TINTED LENSES*

Leo W. Fink, M.D.
Minneapolis

IT IS a fact apparent to all who give sufficient consideration to the subject that tinted lenses are being prescribed by many ophthalmologists in an aimless and indiscriminate manner. That one should have a definite therapeutic object in view when he places a tinted lens before the eye needs no affirmation. Too many refractionists, priding themselves upon the finest detail in attaining scientific accuracy in correcting refractive errors, end their careful work by placing a tint in the lens, giving no consideration to whether it is a therapeutic necessity, but only hoping that it may help. This thoughtless method of prescribing reflects the influence which is exerted by optical firms, who by extensive advertising campaigns lead astray the unwary refractionist inclined to follow routine procedure instead of treating each case as an individual and applying therapeutic measures as they are indicated.

As a result of this routine method of prescribing there are at present a large number of individuals with healthy eyes wearing glasses with a tint which is not only unnecessary for protection but which is actually harmful to retinal adaptation. The healthy eye used with proper hygienic consideration and under normal conditions, making exception, of course, to the extraordinary conditions existing in certain climes or occupations, needs no protection from either the visible or invisible rays.

A great deal has been written about the harmful effects produced by the ultraviolet end of the spectrum, and no doubt many a tint has been placed in a glass to obviate the harm caused by ultraviolet radiation. It is true that this radiation in sufficient concentration has a decided injurious effect upon certain structures of the eye, as has been amply proved by clinical observation and experiment, and even in the concentration present in the solar radiation a few isolated instances of injury have been reported, as in the case described by Syme[1] where a woman developed an erythematous rash and injection of her eyes on a bright summer day (Duke Elder[2] explains this by a sensitizer in the blood); but for the vast majority, nature has provided abundant protection against the ultraviolet ray.

This protection is furnished by the cornea and lens. It has been shown by experiment that the cornea absorbs all rays below 2,900 a.u. and that the lens gives even greater protection by absorbing all rays under 3,500 a.u.

When we consider that the sunlight at lower atmospheres, due to the absorption in the higher atmospheres, contains very few rays under 3,500 a.u. and the lower limit is reached around 2,900 a.u., we realize how well the eye is protected against this particular radiation. According to Abbott,[3] the percentage of waves between 3,050 and 2,910 a.u. at ordinary altitudes averages about 0.25 per cent of the total solar spectrum. Lawson[4] says that in the laboratory the ultraviolet waves average about 200 a.u. It is therefore obvious that it is impossible for very much of the ultraviolet ray to reach the retina under ordinary circumstances.

In granting protection from the heat, or infrared radiation, nature has again been liberal. Injury to the superficial portion of the eye is prevented to a large extent by the moist surface. According to Fuchs,[5] the water in the media absorbs so much of the heat radiation that little, if any, reaches the retina at all. Vogt[6] states that about 25 per cent reaches the superficial portion of the vitreous but causes no harm unless very intense and of long duration. So far as the visible spectrum is concerned, it causes no ill effects unless it is very intense and produces dazzling. As Lawson observes,[4] "The eye of all human races is self-adapted to endure without harm the sunlight of that part of the world in which they live."

The self-evident fact that colored lenses cut down the intensity or brightness of light of necessity raises the question whether this decrease of luminosity is harmful or beneficial. As pointed out by Ferree and Rand,[7] "Increase of the intensity of white light gives a greater power for clear seeing through its enabling the retina

*From the Department of Ophthalmology and Otolaryngology, The Nicollet Clinic, Minneapolis, Minnesota.

to perceive greater detail. Secondly, with a given difference in coefficient of reflection between an object and its background the sensation difference is increased with the intensity of light. Therefore, greater visibility is produced. Thirdly, it narrows the pupil, thus resulting in fewer aberration effects and narrowing the cone of light, which in turn decreases the size of diffusion circles. The effect of increased intensity is to speed up clear seeing, lessen fatigue, and prevent ocular discomforts."

The blurred image of the ametropic eye is cleared considerably by increasing the intensity of light, thereby allowing the retina to see more detail. According to Ferree and Rand,[7] an eye which is corrected for medium and high intensities of light may give much trouble when used in lower intensities. If this is true, it is reasonable to expect that eyes corrected for the light intensities ordinarily used in test charts would not be benefited but would be harmed by tinted lenses, which automatically tone down the intensity of light and force the eye to work in a decreased brightness. Such individuals demand more light to counteract the effect of the colored glass. Increased intensity of light is especially important in elderly people. They have less difficulty in seeing near objects and there is a greater range over which clear seeing is possible. In myopes and hyperopes there is an abnormal relation for accommodation and convergence. In these the strain of attempting to see clearly is much reduced by high intensities of light. It is not, then, the brightness of light which produces the asthenopic symptoms, but it is the faulty lighting arrangements, which cause a faulty distribution of light. Instead of lowering the brightness, more attention must be paid toward effecting a proper distribution. This entails, first, the elimination of unevenness of illumination, which produces glaring and brilliant surfaces; second, the proper diffusion of light; third, careful attention to the angle of incidence; and, fourth, elimination of high brilliancies in the field of view.

It is apparent that many ophthalmologists do not properly appreciate the power of the normal retina for adapting itself to the various degrees of illumination to which it is subjected. This process of adjustment to the illumination present is an experience common to all. An individual who goes from a brightly lighted room into a dark one at first sees nothing, but the longer he stays in the room the more his vision adjusts itself, so that finally he is able to distinguish objects about him. After his vision is adjusted, if he again returns to the brightly lighted room, he finds that at first he is so dazzled that he sees poorly, but after a time the sense of dazzling and poor vision disappears.

This power of the eye to adjust itself to the illumination present is called adaptation, or, specifically, light adaptation. By this process the healthy eye is adjusted to broad ranges of varying illumination and this adaptive power is fully sufficient to keep the eye healthy in all degrees of solar illumination.

It is a fact easily comprehended that tinted lenses impair light adaptation by preventing its exercise, and if it were generally recognized that healthy adaptation is necessary, there would be fewer eyes weakened and made less useful by tinted lenses.

In a statement embodying the principle that tinted lenses are not necessary for a healthy eye, certain abnormal conditions must be considered as modifying factors. These include, first, the intensity of the light to which the eye is subjected; second, the duration of the exposure; third, the presence of glare; and, fourth, the occupation of the individual.

Where a person is subjected to intense degrees of sunlight, protective lenses become an absolute necessity. This condition arises in high altitudes where the absorptive properties of the atmosphere are not so great and consequently there is a high concentration of radiant energy. Experiment has shown that the chief danger lies, not in the ultraviolet radiation, but in the infra-red. Prolonged exposure, even in healthy eyes, produces its effect by lowering the resistance of the individual.

Glare, which is defined as the unpleasant effect produced by excessive reflection from below, is usually caused by reflection from large bodies of water, snow, ice, sand or rock. This light itself may be of moderate intensity, but when reflected from a large body of snow, produces an intense effect. It is estimated that snow reflects 70 per cent of the sunlight. According to Lawson's experiment,[4] the effects of glare are produced by the luminous and infra-red portions of the spectrum. Snowblindness is in reality a sunburn of the conjunctiva. Certain occupations

and trades produce effects from radiant energy due to the excessive concentration of certain wave lengths. It is a fairly well established fact that there is a type of cataract produced in individuals who are subjected to intense heat waves. The ultraviolet wave plays an important role in the ocular disturbances manifested in acetylene welders.

In certain disease conditions of the eye, or in structural defects, either congenital or acquired, it becomes necessary for the individual to use a tinted lens to alleviate the photophobia which is an accompaniment of his ocular disturbance; for here the eye must be protected from ordinary sunlight as there is great sensitivity to light, and here we must put the eye at rest, for, as Fuchs[5] says, the eye is stimulated by light to the performance of its function and shutting out the light is the first requisite.

Photophobia, defined as the discomfort and sense of dazzling and blindness produced by light, originates both in the terminal fibers of the trigeminal nerve and in the retina. These nerve terminals end mostly in the cornea and for this reason superficial inflammations of the cornea are accompanied by marked photophobia. Since the iris has an abundant supply of sensory nerves, there is also marked photophobia when it becomes inflamed. In diseased conditions of the retina photophobia may be a marked symptom, but here it is not the sensory fibers that play a role, but the optical fibers which carry the reflex to the pupil.

Among the structural defects for which a tinted lens is advisable may be mentioned albinism, coloboma of the iris, and aphakia. It may be well here to call special attention to the need for a tinted lens for the aphakic eye. After the extraction of a cataract the eye is deprived of its most effective protection against the ultraviolet light and all aphakic patients should wear a tinted lens out of doors, except on dark days.

When we place a tinted lens before the eye, we have for our object the total or partial elimination of certain spectral radiations. We can, by selecting certain types of glass combined with certain colors, confine our results to particular areas of the spectrum. As mentioned above, the harmful effects of radiant energy are produced by the rays from three portions of the spectrum —the ultraviolet portion, the visible portion and the infra-red portion. It is known that certain types of glass produce this result in a selective manner and in general can be arranged in three groups. In the first group we have the ordinary colored glasses which are produced with no scientific basis and recommended for general use in healthy or diseased eyes. In the second group are those which absorb the ultraviolet rays and in the third group are those which absorb the heat rays. In late years there has been placed on the market a glass which is recommended for absorption of visible rays only.

It is generally agreed that the elimination of the ultra-violet radiation is a simple matter and glasses recommended for this purpose, such as Hygat, Euphos, Crookes and Ultrasin, are quite satisfactory.

In 1925 Sir Arnold Lawson[4] carried out a series of experiments to determine the absorptive power of various tinted lenses. In these studies he used: (1) No. 3 London Smoke; (2) three shades of amber; (3) four shades of Fieusol; (4) Crookes A, A2, B, B2; and (5) peacock blue. Concerning the ultraviolet rays, he concluded that the darker shades of Fieusol were the most effective. Very close to these were placed the Crookes glass; then came amber, and least protective of all was London smoke. All three shades of Crookes were equally effective and did not protect the eye from ultraviolet radiations under 3,500 a. u. The only tints which cut off the ultraviolet completely were the darker shades of Fieusol. Lawson recommended these instead of Crookes for acetylene welders or for use in high altitudes.

In respect to the heat rays, the protecting glasses in general use are deficient, for, as pointed out by Imre,[8] they not only fail to give the desired protection but actually lengthen a considerable quantity of the visible rays and change them to heat rays and thus produce heat behind the glasses. Imre[8] advises that these rays be held back, not by absorption, but by reflection. For the accomplishment of this result he advises the use of thin, transparent, metallic layers which admit a sufficient quantity of the visible spectrum but at the same time have great reflective ability. He has shown that glasses covered with a thin metallic layer of platinum or gold can protect the eye equally from ultraviolet and infra-red and that the visible spectrum can be admitted in any desired quantity. In his clinical practice he finds that the metallic glasses

are very agreeable to the patients, as there is no accumulation of heat behind them, but rather an actual feeling of coolness.

In his experiments Lawson[4] finds that peacock blue is most effective for infra-red absorption and that this is closely followed by Crookes B2 and F 4 & 5, amber being less effective than either.

The luminous rays are cut out equally well by all glasses, but Fieusol 4 & 5 are superior to Crookes in high sunlight and glare, and peacock blue is best in extreme cases.

For active inflammatory conditions in the eyes, Lawson[4] advises the use of peacock blue. Imre[8] is quite enthusiastic over the results obtained in these patients with the use of metallic reflecting glasses. He points out the advantages of less heat production behind the lens. This heat, he maintains, dries the cornea and results in blinking and increased tear production, thus irritating the inflamed eye. From his observation he concludes that these patients are far more comfortable with the reflecting glasses and that the cure is greatly accelerated.

The prescribing of tinted lenses for the apparently healthy eye without tangible and sufficient reason for so doing is a practice to be condemned. It is no more logical and fully as reprehensible to place such a glass before an eye as it is to routinely add a +1 diopter lens for reading because the patient is forty-five years old. It is not only unscientific, but in many cases positively contraindicated. When we stop to realize that under ordinary circumstances the sound eye needs no protection against ultraviolet ray and that the tinted lens cuts down the visible rays from 15 to 35 per cent or more, depending upon the shade, it is inconceivable that we prescribe a tint without full and sufficient reason. The retina is stimulated into activity by visible rays. Any means which lessen this stimulus interfere with the perceptive apparatus to some extent. It is true that certain individuals with apparently sound eyes are made miserable in ordinary sunlight. These individuals may be pathologically affected, in that adaptation is slow or that adaptation, when once effected, is below normal, or they may in reality be mentally or physically abnormal. Very often in physical diseases or neurasthenia, the general function of the eye is impaired and in this type of patient help is needed.

Where the glare exists in moderate amount, attention should be directed to the lighting arrangement and hygienic measures before the easier method of tinted lenses is employed. If this were done, many cases of asthenopia attributed to light effects would be cured without cutting down the luminous spectrum.

In the myopic eye a tinted lens is more often needed. Here it is advisable to use a soft tint to cut down the sharpness of the image.

Ophthalmologists, then, should not be misled by advertising claims of various optical houses which for pecuniary reasons alone seek to popularize the routine prescribing of absorptive lenses, but should consider the absorptive glass as a therapeutic procedure to be used when indicated, and realize that it can be just as harmful to certain eyes as it can be helpful to others.

STONE IN THE UPPER URINARY TRACT: ITS CLINICAL MANIFESTATIONS AND TREATMENT*

PHILIP F. DONOHUE, M.D., F.A.C.S.
Saint Paul

THE clinical picture of stone in the kidney or ureter in the majority of cases is typical. Possibility of the presence of renal or ureteral stone is at once suggested by the history of sharp severe pain beginning in the lumbar region and radiating forward and downward into the genitalia. Such pain is spoken of as renal colic and is scarcely ever mistaken for pain produced by other conditions. Morphine is required and the attack usually ends spontaneously. In many cases complete relief is experienced until a second similar attack occurs. In other cases, in the interval between colics there is constant dull achy pain in the flank of the affected side.

Not infrequently typical colics do not occur and the character of the pain is not suggestive. There may be only a dull achy pain which does not radiate though its location in the flank at once suggests the possibility of renal origin. In other cases not even flank discomfort may be noticed. This is particularly true with ureteral stone. Here there may be only vague discomfort in the upper or lower quadrant. Even the helpful lead that unilateral distribution offers may be lacking, the patient complaining only of vague generalized abdominal discomfort. Because of the atypical character and location of the pain many of these cases are mistaken for cholecystic disease, appendicitis, intestinal obstruction, and other intra-peritoneal conditions. Deaver has said that the possibility of renal or ureteral stone should be considered in any case of unexplained abdominal pain.

Of importance in the history of these cases is the character of the urine voided during or after an attack of pain. When gross hematuria is reported the presence of some lesion in the urinary tract is established and we need no longer concern ourselves with intra-peritoneal possibilities. In more than half the cases the voided urine is reported grossly clear. Unless the specimen is submitted to microscopic examination this fact is of no value in the history. When examination has been made in these cases of clear urine a few red cells are almost regularly found, though their absence does not rule out stone.

In a considerable number of cases, during attacks of pain there suddenly occurs some degree of bladder irritation. When this is marked there is an almost constant and severe desire to void which compels voiding every few minutes with several urethral burning and terminal tenesmus. In other cases the irritation may be nothing more than itching discomfort referred to the urethra and bladder associated with an abnormally frequent but not compelling desire to void, the actual number of voidings being no more frequent than normal. In many cases the bladder irritation immediately disappears with the end of the pain. In other cases the irritation continues and may eventually become the chief symptom complained of. This is particularly true in the event of infection occurring as a complication of calculus disease. Examination of the urine in these cases will show pus cells, and when the infection is marked the urine is often quite cloudy.

The history of the passage of a small stone or gravel during an attack or some time later is, of course, conclusive evidence that stone has been present in the kidney or the ureter. This occurrence is reported in the history of approximately one-third of the cases. When the passage of stone is followed sometime later by persisting flank pain, repeated attacks of colic, bladder irritation, or the voiding of bloody urine, it may be assumed either that multiple stones are present, recurrence of the stone has taken place, infection has occurred, or that some other condition of the upper urinary tract associated with the presence of stone is the cause of these symptoms.

The examination of these patients should contemplate more than mere proof or exclusion of the presence of stone. The exact location of the stone can and should be demonstrated. Associated conditions of kidney or ureter which may have influenced the formation of the stone or are likely to invite its recurrence should be discovered and their importance appraised. Among the conditions found associated with calculus disease that may be considered important in this

*Read before the sixty-first annual meeting of Wabasha County Medical Society, Wabasha, Minnesota, July 11, 1929.

way are loose sagging kidney with kinking of the ureter, anomalous renal vessels causing obstruction at the uretero-pelvic junction, various other forms of ureteral obstruction such as stricture and partial stenosis of the uretero-vesical orifice, various abnormalities associated with obstruction, and finally persisting upper urinary tract infection. Most of the conditions mentioned interfere mechanically or otherwise with the peristaltic activity of pelvis and ureter essential to normal movement of urine and prevention of stasis.

Fig. 1. Plain *x*-ray. Branched stone in right kidney. Medium sized stone in left kidney.

Fig. 2. Bilateral pyelograms. Advanced hydronephrosis of right kidney. Stone in right kidney pelvis. Uretero-pelvic junction obstruction due to aberrant renal artery.

Fig. 3. Plain *x*-ray. Faint shadows in region of right kidney tracing the outline of calyces. (Pyelogram localized these shadows in pelvis.) Single oval shadow above (cortical stone).

Any degree of obstruction impedes the passage of urine from the kidney to the bladder, causing stasis of urine in the kidney pelvis in early cases and hydro-nephrosis in advanced cases. In the cases in which there is an inherent tendency to form stones, recurrences are more likely when there is any degree of obstruction in the kidney or ureter.

Of importance in the management of these cases is the condition of the upper urinary tract on the other side. This information is particularly needed in the cases with stones in both kidneys, since experience has shown the wisdom of operating first on the functionally and anatomically better kidney. In cases of calculus pyonephrosis knowledge that the remaining kidney is capable of good function is essential before nephrectomy can be undertaken safely.

The clinical picture of renal and ureteral stone has been described. Associated conditions frequently found in the examination of these cases that serve as contributing causes in the formation and recurrence of stone have been pointed out. The destructive changes in kidney and ureter resulting from stone have been alluded to and will be further emphasized in connection with the cases to be reported. It is also our purpose to present the treatment of renal and ureteral calculus. In many cases removal of the stone will be sufficient. In cases in which associated conditions are present it will be necessary also to correct these, thus rendering recurrence of stone less likely. The indications for treatment and the various procedures employed are illustrated by summarized clinical records of typical cases, representing many of the circumstances in which stones in the kidney and ureter are found. These reports will also serve to illustrate the diagnostic methods employed in these cases.

Case 1.—Female, 38 years.

Complaint—Frequency of urination. Pain in right flank. Hematuria. Discomfort in left flank.

Present Illness—Began two years ago, following last pregnancy, with pain, frequency and hematuria. Periods during which she voids, every half hour by day and once during the night. Attacks of dull aching pain in right flank prior to one year ago, at which time a severe attack of colicky pain. No typical radiation. Repeated hematuria. Recently vague discomfort in left flank. Tenderness to deep percussion in both flanks.

Urine—Clear. Microscopic: 100 pus cells, moderate number red blood cells.

Plain X-ray—In right kidney field is a large branched stone. In left kidney field is a smaller shadow toward the lower pole (Figure 1).

Cystoscopy—Bladder mucosa shows chronic inflammatory change over trigone and floor. Indigo-carmine

appeared in 5 minutes on left with poor concentration; on right side in 7 minutes, even poorer concentration.

Pyelograms—Left pyelogram shows slight dilatation of minor calyces. Shadow localizes in inferior calyx.

Diagnosis—Renal calculi, bilateral, with infection.

Treatment—Left pelvio-lithotomy (left kidney function best). Complete relief of left sided symptoms.

Three months later right nephrotomy, with removal of multiple calculi. Complete relief of right sided symptoms.

COMMENT

The better kidney was operated upon first for the following reasons: Better function, fairly good anatomic condition, and the presence of a relatively small stone which could be removed by pyelotomy, the preferred procedure. With the function of this kidney improved, radical removal of the branched stone from the remaining kidney was undertaken safely.

Removal of either kidney is avoided in these cases of bilateral lithiasis because of the frequency of recurrence of stone on one or both sides. Even the employment of wide nephrotomy for the removal of large branched stones is justifiable and should be performed in cases in which marked damage of the kidney parenchyma has not occurred. The danger of postoperative hemorrhage following this procedure demands careful hemostasis and this is accomplished by tightly approximating the margins of the calyces with a strong continuous suture after the method of Schwyzer, fortifying this with several deeply placed mattress sutures through the cortex.

Case 2.—Male, 56 years.

Complaint—Hematuria, frequent painful urination. Pain over the bladder.

Present Illness—Four months ago noticed dark chocolate colored urine associated with slight frequency, nocturia two to three times, slight urgency but no burning at urination. Urine cleared in a few days but slight frequency and urgency continued. Bloody urine occurred on four or five occasions. Pain in bladder region at times. Fifteen years ago passed a small stone. Physical examination negative.

Urine—Dark but clear. Microscopic: many pus and moderate number of red blood cells.

Plain X-ray—Large oval shadow in right kidney region.

Cystoscopy—Bladder normal. Slight redness of right ureteral orifice. Indigo-carmine appeared in 7 minutes on the left in good concentration. No dye seen on right after 12 minutes. Ureters catheterized. Seventy-five c.c. cloudy urine aspirated from right kidney, no dye coloring.

Pyelograms—Marked dilatation of right pelvis and major calyces (Figure 2).

Diagnosis—Right hydro-nephrosis. Uretero-pelvic junction obstruction, due to anomalous artery. Renal calculus.

Treatment—Nephrectomy. Complete relief. At operation an anomalous artery accounting for the uretero-pelvic junction obstruction was found.

COMMENT

This case illustrates the production of hydronephrosis due to obstruction at the uretero-pelvic junction by an anomalous renal artery. It is probable that stone formation in this patient was secondary to the stagnation of urine in the kidney pelvis caused by the obstruction. Marked damage to the kidney had occurred and nephrectomy was the rational procedure. In other cases seen earlier, hydro-nephrosis may not be so advanced and the kidney may still be capable of recovering a good deal of its function if the obstruction is corrected at the same time the stone is removed. In such cases conservative surgery is indicated and the anomalous vessel is divided and the stone removed through an incision in the pelvis.

Case 3.—Male, age 45.

Complaint—Pain in right lumbar region.

Present Illness—One year ago sudden attack of sharp pain in right lumbar area radiating into inguinal region. Dull pain ever since. Patient unable to work because of pain. No urinary symptoms. Marked tenderness to deep percussion in right flank.

Urine—Clear. Microscopic: occasional pus cell, no red blood cells.

Plain X-ray—Oval shell-like shadow, size of olive, opposite second lumbar vertebræ on right. Group of shadows in right kidney area closely tracing outline of upper and middle calyces (Figure 3).

Cystoscopy—Slight cystitis confined to trigone. Ureteral orifices normal. Clear jets of urine from each.

Pyelograms—Right pyelogram, moderate hydronephrosis. Oval shadow outside pelvis. Faint shadows localized in upper and middle calyces. Left pyelogram, slight dilatation of true pelvis, sharp bend in ureter.

Diagnosis—Calcareous pyelo-nephritis, right. Cortical renal stone, right.

Treatment—Right nephrectomy after exploration showed impossibility of removal of fine stone particles, and because of good anatomic condition of left kidney. Complete relief.

COMMENT

In this case a kidney capable of good function and showing only moderate anatomic change was excised because it was found impossible to remove all the fine calcareous particles scattered throughout the pelvis and calyces. Any one of these particles would have served as a nucleus for further stone formation. It was also apparent that this calcareous material was due to infection of the kidney by urea splitting organisms of the bacillus proteus group with the for-

mation of alkaline urine and the precipitation of inorganic salts. Infection of the bladder with organisms of this group is responsible for the condition called alkaline incrusted cystitis. All cases of infection of the kidney in which cultures of ureteral catheter specimens show organisms

Fig. 4. Bilateral pyelograms. Horse-shoe kidney. Left renal calculus.

Fig. 5. Left pyelogram. Left ectopic kidney with stone.

Fig. 6. Left pyelo-ureterogram. Moderately advanced hydronephrosis and hydro-ureter. Large stone in left ureter at level of third and fourth sacral vertebra.

of this group should be submitted to vigorous treatment to destroy these bacteria and prevent the formation of calcareous material.

Case 4.—Male, 36 years.

Complaint—Pain in left lower abdomen. Hematuria.

Present Illness—Began six months ago with attacks of pain occurring at two to three day intervals. Pain worse when standing. No urinary symptoms. Blood found in urine at examination for life insurance. Tender in left abdomen along course of ureter and in left costo-vertebral angle.

Urine—Slightly cloudy. Microscopic: moderate number of red blood cells and pus cells.

Plain X-ray—Shadow on left opposite third lumbar vertebra.

Cystoscopy—Bladder normal. Clear urine from right orifice. No jets on left. Indigo-carmine appeared promptly from both sides. Concentration better on right. Ureters catheterized.

Pyelograms—Left pyelogram (Figure 4) shows abnormal rotation of kidney, calyces directed medially, lower ones almost to mid-line. Pelvis moderately dilated. Right pyelograms also show abnormal rotation with calyces directed medially. Lower poles drawn toward one another.

Diagnosis—Horse-shoe kidney. Left renal calculus.

Treatment—Left nephrotomy and removal of stone. Presence of horse-shoe kidney confirmed. Complete relief of symptoms.

COMMENT

This was a case of unexplained abdominal pain. Urologic investigation was prompted by the finding of a few red blood cells on microscopic examination of the urine. In cases of horse-shoe kidney some degree of obstruction at the uretero-pelvic junction is frequently produced by the abnormal relations of the blood vessels, the under rotation of the kidney, and its faulty position. Corrective surgery is often out of the question, and in this case removal of the stone only was performed. Recurrence of stone in this patient would not be surprising.

Case 5.—Male, age 54.

Complaint—Pain in left flank.

Present Illness—Past four years attacks of pain in left side of back. Pain radiates down into thigh. Associated with attacks of pain are periods of frequency and dysuria. At times urine is cloudy. Flank pain constant past eight months. Tenderness left costo-vertebral angle.

Urine—Clear. Microscopic: few pus and red blood cells.

Plain X-ray—Shadow 1x1.5 cm. to the left of the lower sacrum.

Cystoscopy—Bladder normal. Ureteral orifices normal. Indigo-carmine 3.5 min. on right, 5 minutes on left, with better concentration on right. F 6 catheter full length on right, 18 cm. on left. Good flow of urine from right, poor flow from left.

Pyelogram—Left kidney in pelvis over lower portion of sacrum. Calyces fairly normal. Ureter folded over. Shadow localizes in pelvis (Figure 5).

Diagnosis—Ectopic left kidney. Renal calculus, left.

Treatment—Nephrectomy. Complete relief.

COMMENT

Ectopic kidney should not be confused with a loose kidney, which occasionally migrates to the pelvis. The ectopic kidney receiving its blood supply from the aorta or iliac artery at the level

it occupies in the body is in a fixed position and its ureter is usually not redundant. A loose kidney with a much lengthened vascular pedicle is capable of considerable descent which can be demonstrated by pyelograms made in both horizontal and vertical positions and its ureter is redundant. The differentiation between these two conditions is of importance in calculus disease, since stone in an ectopic kidney is best treated by nephrectomy and a loose kidney in good anatomic condition may be appropriately treated by nephropexy after removal of the stone.

Case 6.—Female, 28 years.

Complaint—Pain in left side.

Present Illness—Attacks of pain since childhood. Attacks worse past two years. Pain begins in left lower quadrant of abdomen and radiates up into flank. Occasional passage of bloody urine. Definite tenderness to pressure in left flank and along the course of the left ureter.

Urine—Cloudy. Microscopic: many pus and red blood cells.

Plain X-ray—Fairly well defined shadow in region of lower left ureter.

Cystoscopy—Bladder normal. Chronic inflammatory reaction about left ureteral orifice. Orifice reddened and swollen. Right ureteral orifice normal. Indigo-carmine appeared more promptly and in better concentration from the right side. Resistance to passage of ureteral catheter met on left side at about 4 cm. Passage of catheter to kidney finally accomplished.

Pyelograms—Left kidney pelvis extremely dilated. Ureter markedly dilated. Shadow localized in lower ureter (Figure 6).

Diagnosis—Left ureteral stone with hydro-ureter and hydro-nephrosis. Marked infection of left kidney.

Treatment—Nephro-ureterectomy. Complete relief.

COMMENT

Removal of the entire ureter with the stone as well as the kidney is desirable in cases of marked hydro-ureter due to calculus. If only nephrectomy with removal of the stone is performed the ureter remains as an atonic hollow structure very liable to infection, if this has not already occurred. An infected blind ureter may be the cause of persistent cystitis and require removal at a second operation. In occasional cases carcinoma occurs in infected ureters remaining after nephrectomy and removal of the stone.

Case 7.—Male, 63 years.

Complaint—Attacks of pain both sides of lower abdomen. Cloudy urine. Nocturia.

Present Illness—Past three or four years feeling of distress over entire lower abdomen with occasional sharp severe attacks of pain. Pain usually on left side, but has been also on right. No radiation. Morphine for relief. No bladder symptoms but blood and pus were found in the urine after an attack. Nocturia two to three times. During the past few weeks has noticed swelling of the face and general loss of strength. No tenderness in abdomen, or flanks. General condition fair.

Urine—Clear. Microscopic: 12 pus and 60 red blood cells.

Plain X-ray—Oval irregular shadow to left of sacrum.

Cystoscopy—Bladder normal. Ureteral orifices normal. Indigo-carmine appeared in 8.5 minutes on the left and in 12 minutes on the right. Concentration of dye poor on both sides.

Pyelograms—Marked hydro-nephrosis and hydro-ureter on left. Shadow localizes in left ureter and dilatation begins immediately above (Figure 7). Marked hydro-nephrosis of right kidney pelvis, not as marked as on the left. Right ureter not well outlined.

Diagnosis—Left ureteral stone. Bilateral hydro-nephrosis, most marked on the left.

Treatment—Left uretero-lithotomy. Course of pelvic lavages and dilatations of right ureter. Complete relief.

COMMENT

Lower abdominal pain in this case was diffuse and was not suggestive of lithiasis. Here again urologic examination was prompted only by the microscopic examination of the urine. This case illustrates the value of investigating the opposite kidney even though no symptoms may have been present on that side, and bears out the contention that pyelography together with functional tests are more reliable in demonstrating the anatomic condition of a kidney than functional tests alone. In this case right renal function was within normal limits, as estimated by indigo-carmine after intravenous injection. The pyelogram of this kidney, however, showed advanced hydro-nephrosis, almost as marked as on the left side. In this case a serious mistake might have been made if the left kidney and ureter had been removed along with the stone. The function of the right kidney alone could scarcely have maintained life for any length of time. Nephrectomy would have been preferable in this patient if the right kidney had been anatomically sound. As it was, removal of the stone only was all that could be undertaken safely.

Case 8.—Male, age 29.

Complaint—Right flank pain. Hematuria.

Present Illness—Severe right flank pain began four years ago. Hematuria for two days. Pain lasted four days. Several such attacks. Morphine for relief. Ache in right flank between attacks. No bladder irritation. Marked tenderness in right costo-vertebral angle. Marked tenderness in right lower abdomen.

Urine—Clear. Microscopic: 40 pus cells, 60 red blood cells.

Plain X-ray—Oval shadow 1x0.5 cm. to right of lower sacrum (Figure 8).

Cystoscopy—Edema of right ureteral orifice. Bulging inward of bladder wall above right ureteral orifice. Left ureteral orifice normal. Bladder mucosa normal. Indigo-carmine, intravenously, appeared in three minutes from left orifice. No appearance on right after 12 minutes.

Pyelogram—Right hydro-ureter. Shadow included in ureterogram. Slight dilatation of kidney pelvis, right.

Diagnosis—Right ureteral lithiasis. Obstruction of ureter. Hydro-ureter.

Treatment—Cystoscopic manipulation. Meatotomy of right ureteral orifice. Stone extracted from ureter. Stone removed from bladder with cystoscopic Rongeur. Complete relief.

Fig. 7. Bilateral pyelograms. Advanced hydronephrosis and hydro-ureter with infection. Large stone in left ureter 5 cm. above uretero-vesicle orifice.

Fig. 8. Plain *x*-ray. Right ureteral stone just above uretero-vesical orifice. (Removed by cystoscopic manipulation.)

COMMENT

Many stones impacted in the vesical portion of the ureter or just above this point, may be removed by cystoscopic methods. Several attempts to remove such a stone should be made before more radical operative removal is resorted to. The employment of this manipulation should be contingent on: (1) good condition of the patient; (2) investigation of the case showing that nephrectomy is not necessary and that removal of the stone will be sufficient; (3) no associated conditions present in the upper urinary tract demanding operative treatment; and (4) that further significant damage to the kidney by the existing obstruction during the time consumed in these manipulations is unlikely.

Case 9.—Male, age 21.

Complaint—Pain right lower abdomen. Ache in right flank.

Present Illness—Began two months ago with sudden sharp pain in right lower abdomen, referred upward toward crest of ilium. Two such attacks since. Morphine for relief. Discomfort in right flank noticed occasionally since first attack. No urinary symptoms. Marked tenderness in right lower quadrant. Moderate tenderness in right costo-vertebral angle.

Urine—Clear. Microscopic: no pus, few red blood cells.

Plain X-ray—Indistinct shadow, small, in region of lower right ureter. Subsequent plates showed no shadows.

Cystoscopy—Bladder normal. Indigo-carmine appeared in 4 minutes on the left. No appearance on the right after 10 minutes. Ureteral catheter F 6 passed full length on right. Twenty c.c. of urine immediately aspirated from right kidney pelvis. Patient immediately experienced relief.

Pyelogram—Right pyelogram normal. Negative for stone.

Cystoscopy—Soft wax bulb passed through length of right ureter. Examination after removal showed two or three linear scratches.

Diagnosis—Right ureteral lithiasis, impacted. (Permeable stone.)

Treatment—Cystoscopy. Ureter dilated to F 12. Seven days later patient passed stone during voiding. Stone .5x.35 cm. Recovery complete.

COMMENT

This case might have been mistaken for acute appendicitis when first seen because of the nature and location of the pain and the absence of urinary symptoms. However, discomfort had been noticed in the right flank and there was tenderness in this area to palpation. Of particular interest in this case is the method employed to diagnose the stone in the ureter. *X*-ray examination on one occasion showed an indistinct shadow

but several subsequent examinations showed no shadows suggestive of calculus. Although the patient carefully strained his urine at each voiding no stone was recovered. A soft wax bulb was passed to and fro in the ureter of the affected side. This method is recommended in cases in which typical colics are repeated, no stones are passed, and *x*-ray examinations and pyelography are both negative for calculus. In many cases the presence of soft stones in the ureter that cast no shadow on an *x*-ray plate can only be diagnosed in this way.

CONCLUSION

In conclusion it should be emphasized that there are an appreciable number of cases of renal and ureteral stone with symptoms that may be indefinite or misleading. It will be necessary to keep a sharp lookout for these cases if they are to be recognized. A carefully taken history with proper appraisal of the facts obtained is essential. Cases exhibiting typical colics should never be mistaken for anything else. The presence of stone should be considered very probable in cases with pain of any sort associated with urinary symptoms. Following Deaver's axiom, any cases of unexplained abdominal pain should be suspected of having calculus. All cases exhibiting these features should be investigated. The information furnished by cystoscopy, ureteral catheterization, divided functional tests and pyelography will lead to a diagnosis and enable one to decide between conservative and radical treatment. In many cases removal of the stone will be sufficient. In all cases the possibility of associated conditions causing stasis and influencing the formation of stone should be kept in mind. In addition to removal of the stone these conditions should be recognized and corrected when present. Conservation of kidney tissue will be effected and the instances of recurrence of stone will be kept to a minimum.

LYDIN NOT ACCEPTABLE FOR N. N. R.

The Council on Pharmacy and Chemistry reports that "Lydin," a product of the Harrower Laboratory, Inc., is claimed to be "a physiological sex-stimulant of note" consisting of a combination of "the male sex hormone" with "the antisterility fat-soluble Vitamin E." It is marketed in capsules for oral administration and is recommended for use in the treatment of impotence with the suggestion that "the indications are too well known to be enumerated." The Council publishes a report on the biologic assay of "Lydin" by T. F. Gallagher sent to the Council by F. C. Koch, head of the Department of Physiological Chemistry and Pharmacology of the University of Chicago. This study shows that when administered by mouth "Lydin" is without effect as measured on capons by the comb growth method or on guinea-pigs as measured by the spermatozoa motility test. Brown-Sequard was convinced that an extract of the testes promoted the vitality, but his experiments were not confirmed or accepted. In the meantime, the available knowledge of the glands of internal secretion has aroused commercial promoters to the exploitation of all sorts of glandular extracts and combinations without an iota of evidence to show that any preparation of extracts of the testes, singly or in combination, has ever been shown to have the slightest effect on the human body when given by mouth. (Jour. A. M. A., July 19, 1930, p. 201.)

CARCINOMA OF THE STOMACH*

Karl W. Anderson, M.D.
Minneapolis

THE prevalent attitude towards carcinoma of the stomach is a pessimistic one. Such an attitude of hopelessness does not tend towards progress, either in research or in regard to aggressive treatment. The internist has in the past assumed this detrimental attitude more than the surgeon. One of our recent associates in the University Hospital told the students that the proper treatment of carcinoma of the stomach when the diagnosis was made was to give the patient some white powder in a palliative fashion, as they all soon die, from the disease. Eventually we all die, but to put this time as far in the future as possible is one of the aims of the medical profession. It is evident that to do this we must assume an aggressive attitude. It is with this spirit that we best attack the problem of carcinoma of the stomach. This aggressive spirit is just as important in the diagnostic field as it is in the surgical. This is illustrated by the following case.

D. W., aged 67, was operated upon by Dr. O. H. Wangensteen. Since August, 1929, the patient had had epigastric distress, consisting of a sensation of fullness immediately after meals, even following small meals. The use of alkalies or frequent feedings gave him no relief. The only relief he noted was obtained by belching. The patient had no history of pain, nausea or vomiting nor any food intolerance. Tarry stools were never noted. Since August, 1929, he had lost thirty pounds in weight. He was sent to the University Hospital in January, 1930. He was a white, senile, emaciated individual who was ambulatory and in no apparent distress. In his abdomen there was tenderness and pain on palpation, but no definite mass could be felt. The gastric analysis showed a total acidity of 14, but no free HCl. Occult blood was found in the stool in all examinations. Blood chemistry was within normal limits, but morphologically his blood showed a secondary anemia. The interest in this case centers itself on the gastrointestinal tract. Fluoroscopic examination by Dr. L. Rigler showed a large filling defect on the greater curvature of the stomach and within this area a large ulceration could be made out near the greater curvature. In the distal third of the stomach there was an infiltration that appeared to be more scirrhous in type and extended mostly along the lesser curvature. Some peristalsis could be made out along the greater curvature in this region. The pylorus was wide open, suggesting infiltration, and the barium meal poured through very rapidly. The whole picture was quite characteristic of an advanced malignancy with ulceration. The duodenal bulb filled out well and appeared normal. There was marked dilatation and regurgitation in the second portion. At the end of six hours the head of the meal was in the cecum and a small amount of barium could be made out in the upper portion of the stomach which was probably in one of the ulcerated areas. Conclusions: Carcinoma involving three-fourths of the stomach.

In spite of the fact that this case involved so much of the stomach no metastasis could be demonstrated. That is, no rectal shelf, no enlarged glands, no nodules in the liver or umbilicus, no jaundice nor metastasis in the lung. Dr. O. H. Wangensteen did a total gastric resection in which the lower inch of the esophagus had to be removed. The end of the esophagus was anastomosed to the jejunum and an entero-anastomosis between the afferent and efferent loops of the jejunum was made. Fluids were started by mouth on the fifth day. He made an uneventful recovery and is now up and around and is eating a semi-solid diet without any discomfort.

It is interesting to speculate on what will happen to the part of the small bowel that was anastomosed to the esophagus. It is evident that the small bowel has a great power of dilatation and hypertrophy. This was evident in a case of multiple stenosis of the small bowel that was recently on our service. Pouch-like enlargements were noted all through the small bowel when a barium meal was given. These pouches simulated stomachs, in size and shape. We anticipate that part of the small bowel used in the anastomoses will dilate and become hypertrophied. Barium meal examination done March 10th showed a beginning dilatation of cone-like enlargement in this area. He has no diarrhea. There are one or two formed bowel movements daily.

So far surgery is the only salvation in this type of case, and it is only by the aggressive attitude that a few of these carcinomas of the stomach, usually called inoperable, have any chance whatever.

In the past I believe we have been prone to call a case inoperable on insufficient data. A

*From the Medical Service, University Hospital, Minneapolis. Presented before the Minnesota Society of Internal Medicine, Duluth, May 26, 1930.

pathologist[4] in London has made the observation that from 20 to 25 per cent of all cases of carcinoma in his series that died unoperated had no lymph node involvement and no metastases, therefore they were purely local growths. Surely it is more important to explore a few abdomens than to have such a large percentage in one series where gastric resection was not attempted. It is true that no one can state the time when metastasis occurs, but when one is unable to demonstrate any metastasis clinically or by roentgenological examination, the advisability of laparotomy should be considered. In some cases where laparotomy previously has been performed and the growth considered inoperable, a second exploration is not out of order if, when the patient comes under one's observation, there is no evidence of metastasis. This is especially true in cases where the previous operator had limited experience. This is illustrated in the following case.

Mrs. S., seventy-five years of age, complained of pain in the epigastrium, loss of weight, nausea without vomiting and loss of appetite. For approximately two years the patient had been having gastrointestinal symptoms. The pain in the epigastrium seemed to have no relation to meals and she found no medication that gave her relief. The type of food that she ate did not appear to affect the pain nor increase her nausea. She gradually lost weight, from 185 pounds to 148 pounds, most of this during the preceding three months. She went to a hospital in June, 1929, where an operation was performed. The surgeon stated that he could do nothing for her and closed the abdomen. Three months after the exploratory operation, September, 1929, she was admitted to the University Hospital, because of gradual increase of her symptoms.

Physical examination revealed nothing of note except in the midepigastrium where there was a small palpable tumor, rather indefinite in outline. Blood showed hemoglobin 51 per cent, red blood cells 2,800,000, white blood cells 8,600. The blood Wassermann reaction was negative. Occult blood was present in the stool on each examination. *X*-ray examination of the stomach and duodenum revealed a characteristic filling defect in the pyloric portion of the stomach just proximal to the pylorus. This extended up to the junction of the pyloric and the middle third of the stomach. The appearance suggested a scirrhous type of carcinoma, but there were several nodules projecting into the lumen of the stomach. The duodenal bulb showed considerable deformity, and there was also some deformity of the second portion of the duodenum. This might have been due to pressure or to perigastric and periduodenal adhesions. The diagnosis was: carcinoma of the stomach, pyloric end, probably operable. A second exploration was advised. Because of the condition of the blood, several transfusions were given before and one immediately following the operation. Partial gastric resection was done. The operation was performed on September 23, 1929, by Dr. W. T. Peyton. The patient is gaining weight, has relief from her original complaints and is doing her own housework. Gastrointestinal *x*-ray study the 20th of June, 1930, revealed a normally functioning gastric resection. No evidence of metastasis in any part of the body could be found.

It is evident in cases like the ones just cited that no thoughtful surgeon or internist would claim a definite cure. But both patients have been given the only existing chance and life has been prolonged. How soon, if at all, the cancer will recur no one can state, but by pursuing the attitude thus exemplified a number of patients will enjoy a long period of relief.

We have noticed that many of our cases of carcinoma of the stomach, where there is a definite palpable mass, turn out to be operable in spite of the size of the tumor. In other words, it often appears that large, palpable carcinomas are purely local growths.

In many cases where there are vague symptoms only and no mass is palpable, the diagnosis is difficult. In these cases we rely upon the *x*-ray and fluoroscopic examination for the early diagnosis. The most important information is obtained by means of the fluoroscopic observation and the *x*-ray films chiefly serve to fix the impression gained from the fluoroscopic examination. It is our opinion that all patients in the cancer age who have gastrointestinal symptoms should have a barium meal examination and this should be repeated from time to time as long as the gastro-intestinal symptoms go unrelieved. This is especially true in cases where occult blood is found in the stool. Any case that shows persistent occult blood in the stool and where no satisfactory explanation therefor can be found, we believe should be considered for an exploratory laparotomy. Sometimes the cause of occult bleeding from the gastrointestinal tract is very difficult to unravel, requiring detailed studies. Where there is an *x*-ray report of a suspicion of a cancer in the stomach and occult blood is present in the stool, there is definite indication for exploration.

When a patient has been carefully studied and a diagnosis such as chronic gallbladder disease has been made and the patient subjected to operation but when after the operation no diminution of the symptoms is noted, we are likely to try to get rid of such a case in any way possible. The importance of post-operative follow-up work constantly impresses itself upon us. Thus we

have learned how easily a cancer of the stomach might be overlooked. Time and again this point is brought home to everybody who tries to carry out a systematic follow-up work on his patients. Thus we are trying to use as a working hypothesis that every patient in the cancer age has a potential malignancy until otherwise proven. The case of Mrs. F. illustrates this.

A housewife, aged 45, was admitted to the University Dispensary, in June, 1925, complaining of pain in the abdomen which was constant and gnawing, especially in the right upper quadrant. The condition was made worse by greasy foods and coffee. By occasional vomiting, unrelated to meals, the patient obtained almost complete relief. Soda and other medications gave no relief. The symptoms were of two years duration. The patient was constipated most of the time.

Physical examination was essentially negative except for moderate tenderness over the right, upper quadrant. *X*-ray examination of the gall-bladder showed no evidence of filling. *X*-ray examination of the stomach and duodenum showed no abnormalities. Gastric expression showed free HCl. Hemoglobin 80 per cent, red blood cells 4,500,000, white blood cells 7,200. In August, 1926, the patient was referred to the University Hospital where an appendectomy and cholecystectomy were performed. The stomach and duodenum were reported negative on direct palpation during the operation. The gallbladder and appendix appeared normal, but were removed and the patient made an uneventful recovery. Five weeks after the operation all her original symptoms returned. In January, 1927, she returned to the University Dispensary for further study. This time she complained of frequent vomiting after meals. Her weight was 134 pounds. Her best weight had been 160 pounds. *X*-ray of the gastrointestinal tract showed no abnormalities.

In October, 1927, she re-entered the hospital and physical examination was negative. Her weight was 106 pounds. Blood: Hemoglobin 90 per cent, red blood cells 4,500,000 and white blood cells 5,100. Stool examination was positive for occult blood on one examination. Gastric expression showed no retention, a free HCl of 6 and a total acidity of 20. *X*-ray examination by Dr. L. Rigler showed a normal stomach in size, shape and position. There was, however, an area on the lesser curvature in the middle third of the stomach extending from the junction of the proximal and middle third down to the junction of the pyloric and middle third which showed definite infiltration, rigidity and absence of peristalsis. There was some spasticity on the greater curvature of the stomach opposite this infiltration. The meal passed through the stomach without hindrance and the remainder of the stomach appeared normal. There was some slight suggestion of ulceration in the region of the infiltrated area. Conclusion: carcinoma, middle third of the stomach, lesser curvature, scirrhous type. No metastasis could be demonstrated in the liver, lymph nodes or lungs. There was no rectal shelf nor was there at any time any jaundice. November 9, 1927, she was operated upon. The surgeon at first could find nothing and he wanted to close the abdomen, but the internist and the roentgenologist present at the operation insisted that the operator open the stomach and palpate the inside. This was done and he felt an infiltration in the area suggested by *x*-ray. Large lymph nodes on the greater curvature of the stomach were noted. The midportion of the lesser curvature of the stomach was occupied by an indefinite, indurated, thickened area. The size was approximately 2 cm. in diameter. The posterior wall of the stomach was adherent to the pancreas. A partial gastrectomy was performed. She made an uneventful recovery. The pathologist reported a small, firm, flat tumor of the lesser curvature of the stomach, 2 cm. in diameter, with edges slightly elevated. Microscopic examination showed thin infiltrating cords of epithelium resembling lymphoid cells and there was marked fibrosis. Diagnosis: scirrhous carcinoma.

Her symptoms did not recur and the patient gradually gained weight. Since her operation she has gained approximately forty pounds and has no gastric symptoms. At this time we are unable to demonstrate any metastasis or recurrence in the stomach.

In this connection it is probably fitting to cite another case where Dr. F. W. Bissell,[2] formerly roentgenologist of the University Hospital, made a diagnosis of early scirrhous carcinoma of the pyloric end of the stomach. An exploratory operation was performed but the surgeon claimed he could find no carcinoma. But, he did not open the stomach. Ten years later the patient died at the Ancker Hospital in St. Paul, and at necropsy a scirrhous carcinoma involving the entire stomach was found. This demonstrates a point successfully fought out years ago in regard to duodenal ulcer and equally true in regard to explorations for cancer of the stomach; namely, that an explorative laparotomy cannot be accepted as negative until the stomach has been palpated from the inside.

In this connection I wish to cite a case related by Dr. E. T. Bell,[1] chief of the Department of Pathology. A diagnosis of carcinoma of the stomach had been made and an exploratory operation performed. The surgeon found numerous large glands in the region of the stomach. He removed a few of them, but thinking that the carcinoma was inoperable because of the glands, no gastric resection was done. Section of the nodes showed a scirrhous carcinoma. The patient was practically symptom-free for two years, but after four years died from scirrhous carcinoma involving practically the entire stomach.

An interesting phase of the subject is being

studied by Dr. J. Sagel,[3] Fellow in the Roentgenological Department at our hospital. In a series of approximately fifty cases of carcinoma of the stomach that have been studied by the Roentgenological Department for the last ten months, approximately 75 per cent have seen a physician because of gastrointestinal symptoms six months to a year before they were referred to the Dispensary or had any gastrointestinal study. That means that the majority of cases in this series had seen their doctor early, had had a superficial examination and been given some prescription and usually a diet and told to report back in from two weeks to a month. The majority of these cases were in the so-called cancer age. It is significant that 5 per cent of the cases were examined behind the fluoroscopic screen by the local physician from two to four weeks previous to the admission to our hospital and told that the stomach and duodenum were normal. These facts are worthy of serious consideration from several points of view. For one thing they bring up the question of the value of fluoroscopic examinations of the gastrointestinal tract when done by the general practitioner who possesses an *x*-ray machine but who has had little special roentgenological training. It is a commonplace to state that every patient who is being subjected to the expense of *x*-ray examination is entitled to have the work done by a competent roentgenologist. Of course, to do a routine gastrointestinal *x*-ray study of all cases in the cancer age would mean a tremendous expenditure of time and money, and it is questionable whether it would be justified. In our hospital it is a routine procedure that all cases on the Medical Service and in the Dispensary have at least two stool samples studied especially for blood, pus and mucus. Whether there is gross blood present or not, a sample from the inside of the stool is examined for occult blood and if such is present the assumption that it comes from high up in the gastrointestinal tract often proves correct.. This simple procedure is an inexpensive check that might be correctly used as an indication for complete gastrointestinal study. In the last month in our hospital two cases of carcinoma of the stomach were discovered in this way.

Many private surgeons as well as hospitals have reported cures in carcinomas of the stomach of from five to ten years duration. Dr. Arnold Schwyzer of St. Paul has a unique series ranging from eight to twenty-four years of freedom from recurrence after removal of the cancer. He has in his experience six instances of cures lasting more than eight years. Three of them have been definitely proven to have had carcinoma. In the others the specimens have been lost.

Mr. B. was operated on by Dr. Schwyzer,[4] September, 1915. A large carcinoma involving two-thirds of the lesser curvature and one-half of the posterior wall was found. It was adherent to the liver. A large piece of the liver was removed with the mass. Microscopic examination revealed an adenocarcinoma. This patient is today living and well.

Many of his patients have had a gastrointestinal history lasting from three to five years before any operation was attempted, and it is surprising how many of them were favorable for resection. This is illustrated by the case of Mr. B., sixty-six years of age, who was operated on in April, 1915. His symptoms dated back three years and for one year he had severe pain, nausea and vomiting with a marked loss of weight. A radical resection of the stomach was made and the patient is still living at the age of 80. Dr. Schwyzer also has a patient that he operated on in 1905 and the specimen is in the Museum of the Department of Pathology, University of Minnesota. A partial gastric resection was done for a large carcinoma. At the time of the operation he was sixty years of age. He died last fall at the age of eighty-four. In other words he enjoyed twenty-four years of life that he could not have had if he had not been operated upon by an aggressive surgeon. Other cases are reported in literature similar to the above mentioned; enough to encourage us in our aggressive stand.

In the statistical approach to the study of carcinoma of the stomach one must not lose sight of the fact that although it gives some definite information concerning what has been done in the past with carcinoma of the stomach, it is evident that it tells nothing concerning what can be done. Statistical studies are important, but we must be careful concerning the interpretation of the results. It appears from this type of study as though the carcinomas were on the increase, but when one considers that more people are living to the cancer age, one has to defer the interpretation of the apparent increase and at present it is permissible to doubt that any real increase has taken place.

When one studies the favorable cases reported in the literature one is impressed with the fact that they are not the results of chance diagnoses, I mean not picked up without symptoms in the course of routine examination. In the majority of cases the diagnosis was due to thorough, persistent diagnostic work by those in charge. Most of the cases had symptoms referable to the gastrointestinal tract and through proper study and interpretation the right diagnosis was reached. Hence, the correct treatment was instigated. Of course in some cases metastases occur early. That is, there is an early breakdown in the lymph node barrier but there is the question whether these cases are not in the minority. Most of our cases that prove inoperable are so because of local infiltration into the surrounding tissues. If this is correct, it gives encouragement, for in this type timely diagnostic work should lead to decrease in mortality. This reminds me of a case referred to the University Hospital from a town not so far from the Mayo Clinic. I say this to show how close the doctor was to competent roentgenologists and yet he did not use them. The patient was a prominent man of forty-eight years of age who wanted good service. He went to the local doctor complaining of belching gas, food idiosyncrasies and distress in the upper part of his abdomen. The doctor treated him for ten months with a bland diet and powders. An examination of his stools was not made nor was the patient subjected to an *x*-ray examination, although he was close to one of the greatest medical centers in the world. At the end of ten months the patient became dissatisfied and came to the University Hospital, where a subsequent examination showed an inoperable carcinoma; inoperable, not because of metastasis in other parts of the body, but because of the extension and infiltration of the tumor into the surrounding tissues. If the unfavorable statistics reported are made up of many cases of this type there is a chance for a marked improvement. As the result of the propaganda which is being spread over the country educating the laity to go to the doctor early, the burden of the early diagnosis is being shifted to the medical profession. It is imperative that we take up the challenge so that the statistics in the future will not indict us for not having done our part.

In summarizing I might state that an attitude of pessimism has been associated with carcinoma of the stomach to an extent which, I believe, is detrimental. More emphasis should be placed on stool examinations. All patients in the cancer age that have gastric symptoms warrant a fluoroscopic and *x*-ray examination. An exploratory operation is indicated when a malignancy of the stomach is suggested and it is not complete until the stomach itself has been opened and palpated from the inside. A large carcinoma of the stomach is not necessarily inoperable; in fact some of the largest carcinomas have given the best results from operation. Sufficient instances of cure of carcinoma of the stomach over three, five, ten and even twenty year periods are found in the literature to justify a more optimistic attitude.

AMBROSE PARÉ—MILITARY SURGEON

HAROLD EDWIN HULLSIEK, M.D., F.A.C.S.
Saint Paul

"TREPAN the King!" cried the doctors with horror.

"And what is the nature of this operation?" asked the Duke de Guise.

"It is little known, monseigneur," said the surgeon. "It is an operation with an instrument invented by myself, and which I call a trepan, making on the top of head, or rather on the lateral part of the brain, an opening the width of an angelot."

"God of mercy!" cried Catherine de Medici indignantly, "Pierce the king's head! And you would have done it!"

"Yes, madame," replied Ambroise, simply.

Although the above lines of Dumas are taken from what is probably a purely imaginative account of the fatal illness of Francois II, it presents a very complete picture of Ambroise Paré, his professional and social contacts, scientific attainments, and his simple and unswerving adherence to the dictates of his medical conscience in a crisis. All about him ran rampant intrigue, plots, wickedness, lust for power, superstition, with poisonings, assassinations, and loss of heads commonplace events, yet anyone familiar with the character of the great Paré would know that in the face of so desperate a situation he would hew straight to the line, and if the king needed to be trephined, trephined he would be.

Born in Bourg Hersent, now part of the city of Laval, in the province of Maine about the year 1510, little did the cabinetmaker's son know, when he was first put out to board with the cleric, that he was to occupy an honored position as physician and friend to the royalty of France during one of the most glamorous periods in her history. Beginning his medical career in the early part of that century during which his country was to experience some of her most terrible days: civil, religious, and foreign wars; political and religious persecution; wicked extravagance and wanton waste; stark poverty, misery, and suffering; with the Field of The Cloth of Gold as one extreme and the salt tax as the other; he was destined to be confidant and medical adviser to many of the principals in the great drama.

Catherine de Medici, licentious, bigoted, crafty, the instigator of the Massacre of Saint Bartholomew; the terrible woman's three degenerate sons, Francois II, husband of Mary Queen of Scots, Charles II, weakling, under whose reign the wholesale slaughter of the Huguenots took place, and Henry II, who caused the murder of the Duke de Guise and his brother, the cardinal; Margaret of Angouleme, Queen of Navarre—the marrying and murdering daughter of the King of Scotland and Mary of Guise, whose schemes finally lost her her head; Diana de Poitiers, fascinating mistress of Henry II; Henry III, the thirteenth and last Valois king, whose family ruled for two hundred and sixty-one years; Admiral Coligny, the celebrated naval general and Huguenot leader; Rabelais, monk, doctor and humorist, whose ribald pen wreaked havoc with the evils of the time; Montaigne, the philosopher; Montmorency, the soldier; the entire family of Guises; and a host of others. What a calling list! What a practice! The fact that he continued to act in as confidential a capacity as that of physician to such a host until his eightieth year is the best testimonial as to his courage, sagacity, honesty, and technical skill that one could wish for.

Paré is known as the father of modern surgery, and since much of his wisdom and experience was gained through his duties with the armies on the various campaigns, he was essentially a military surgeon. As a boy, he was sent to live with an ecclesiastical gentleman for the purpose of learning Latin. Whether or not this was done with the idea of a medical career in mind we do not know, but at any rate, he acquired no knowledge of Latin, the pious one keeping him busy with other tasks than those leading to a classical education. Soon we find him apprenticed to a barber-surgeon, who taught him bleeding, cupping, leeching, and such other duties of his calling that he deemed essential. The barber-surgeon, Laval, was unable to teach him the Latin so necessary to the surgeon of the day, and this failing, which he never corrected, was to bring upon him much adverse criticism and ridicule

by his confreres in later years. He remained for some time with this master, and then, through what influence is not known, became a *compagnon chirurgien,* a sort of interne or resident physician at the Hotel Dieu. This was the only public hospital in Paris, having been founded in the seventh century, and although under the management of the Canon of Notre Dame at the time of his stay there, became the battle ground for the then frequent altercations among the various classes of the medical profession.

In France during the early part of the sixteenth century the practitioners of medicine were divided into three groups: the physicians, the surgeons, and the barber-surgeons. The first class belonged to the Faculte de Medicine, and exercised an autocratic supervision over all who practiced the art; the surgeons, members of the Confrerie de Saint Come, wore long robes, and deigned to treat surgical conditions by means of ointments, plasters, and cauterizing agents only, and would not stoop to perform operations; the barber-surgeons did venesection and cupping. Each group encroached on the fields of the other groups, all were jealous, and the rowing and bickering was furious and continuous.

An old work enumerates the following table of the practitioners of medicine, possibly a short time later than the early sixteen hundreds, and probably including Germany as well as France, but for the purpose of illustration, gives a good picture of the chaos that existed at the time.

I. Medical practitioners proper.
   a. Medici in general, commissioned, court, field, hospital, and plague medici.
   b. Surgeons, barbers, regimental surgeons, oculists, herniotomists, lithotomists, bath-keepers.
   c. Superior sworn midwives, ordinary midwives, inferior midwives, nurses.

II. Sundry impostors and pretended physicians. Old Women, village priests, hermits, quacks, uroscopists, Pseudo-Paracelcists, pyrotechnists, Jews, calf-doctors (emetic-peddlers), executioners, crystal romancers, mountebanks, vagrants, magicians, exorcists, monsters, wood-hermits, rat-catchers, bankrupts, jugglers, gipsies, professors, veterinary physicians, and (*sic*) etc.

After three or four years at the Hotel Dieu, a period concerning which we have meager information, he left, and about the year 1536, began his military career as a surgeon with troops. At this time Anne de Montmorency led the French army away on a campaign in which they followed the retreating forces of Charles V across the Alps, finally ending up in Turin, where a considerable time was passed. Paré acted as surgeon to Mareschal de Montjan, a position he held for two years until the death of his chief, when he returned to Paris. During this campaign his duties were many and arduous. If the army surgeon of today imagines that his task is a difficult one, let him glance at the order given the field surgeon of Paré's time. In addition to superstition, ignorance, sorcery, Black Magic, etc., he had to contend with a dismal lack of knowledge of anatomy, psysiology, and pathology as we know them today. Wounds almost invariably became horribly infected with the result that amputations were universally done in cases where today such a procedure would be entirely unnecessary. The following is a short list of the ordinance used to keep the surgeon busy. "There we found," says Ambroise, in his "Apology and Treatise," "everyone in arms, tocsin sounding from all sides, yea, for five or six leagues about the harbors, to wit, Brest, Couquet, Crozon, le Fou, Doulac, Laudenac, each well-furnished with artillery such as cannon, demi-cannon, bastards, posse-volants, field-pieces, culverines, serpentines, basilisks, sakers, falcons, falconneaux, flutes, orgues, arquebuses a croc, ..." Add to this imposing arsenal such toys as halberds, pikes, axes, javelins, swords, daggers, clubs, bars of iron, chains, grenades, lances, torches, fusees, melted lead, and quick-lime (to put out eyes) and it is small wonder that the good Paré frequently had his ingenuity tested to the point of entirely novel therapeutic measures.

It was in this his first campaign that he cast aside the time-honored custom of cauterizing wounds made with firearms. According to tradition and because gunpowder wounds "participate of venomosity" they must be treated with boiling oil, notwithstanding the

attendant pain and bitter objections on the part of the patients. So great was the carnage in the battle about the Chateau de Villane that the supplies of the young surgeon became exhausted and he presently found himself with many wounds still to be treated and no oil remaining. Necessity mothering invention, he conceived a dressing of egg-yolk, oil of roses, and turpentine. During the night he became so worried concerning the wounds he had dressed in so radical a manner that sleep was impossible, and after tossing about all night, he arose at dawn to inspect his wounded. He was overjoyed to discover that those which had been treated with the new ointment were quite comfortable, while the wounds of those burned with the hot oil were feverish and swollen, and the unfortunate victims writhing and groaning in pain. "Then," he writes, "I resolved with myself never more to burn thus cruelly men wounded with gunshot."

Although humble enough at times (one of his favorite expressions being *"Je le pansai, Dieu le guérit"*) he is Cellini-like enough at others. In apology for the latter characteristic it might be suggested, however, that with the jealousies and obstructions he was forced to combat among his confreres, a shrinking nature most certainly would have got him nowhere. He remarks of the soldiers fighting among themselves and modestly says, "If there were four wounded I always had three of them, and if it was a question of cutting off an arm or a leg, or to trepan, or to reduce a fracture or a dislocation, I brought it well to an end." In consultation, if there was any serious piece of surgery to do, he was always the one chosen to do it, and he always did it "promptly and dextrously, and with great assurance," so that the other surgeons wondered at such skill in one so young.

As has been said, parts were lopped off ruthlessly, and by no means always unnecessarily, since the prevalence of infection in traumatized wounds often meant a fatal termination, whereas a more or less cleanly made amputation gave the patient at least an even chance. Tradition dictated that all amputation wounds be seared with white-hot irons, and a set of cauteries were a regular part of the military surgeon's armamentarium. Paré had for some time been mulling over the idea of supplanting the cautery with the ligature as a means of controlling hemorrhage after amputations. In fact he had discussed it some time earlier with two confreres who agreed that it might be safely attempted. In 1552 he amputated an officers' leg, and instead of using the hot irons to close the great vessels, he tied them securely with ligatures. He writes about his patient, "He returned home gaily with a wooden leg, saying that he had got off cheaply without being miserably burned to stop the bleeding." This innovation was to bring about countless arguments and objections from the conservatives, and it was years before the practice became generally accepted.

In 1554, at the age of forty-four, he was made a member of the College of Saint Come, and being no longer a barber-surgeon, was allowed to wear the long robe which was the surgeon's distinguishing mark. It was no secret that he was ignorant of Latin. In fact he voiced loud defies to the effect that the French tongue was good enough for anybody to speak or write. His inability to use the language of the surgeons was more than offset by his now recognized technical ability and experience, and also, what was by no means a trivial consideration, his influence with the nobility, so that it was considered expedient to admit him by means of an examination in Latin that even he could pass. After having spent the better part of fifteen years campaigning, he now set himself to work studying anatomy and rewriting one of his books, in which manner he passed the ensuing three or four years.

In 1559 he was saddened by the death of his king and friend, Henry II, also dramatically and incidentally incorrectly described by Dumas. The king, riding in a tournament and wearing the colors of the beautiful Madame de Poitiers was laid low by a blow over the right eye with a lance in the hands of Gabriel de Montgomery. Although Dumas has it that Paré was at Peronne and was not called to attend his majesty, it is a fact that both he and Vesalius were among the surgeons who were with him in his last days. Though numerous consultations were held, the splinters of the lance could not be located, even after the surgeons experimented with the heads of

four recently beheaded criminals, driving lances into the skulls in an effort to determine the direction taken by the fragments. The king died on the eleventh day and in his works Paré describes very accurately the postmortem findings in the royal brain.

Throughout his long lifetime he was constantly observant and always eager to avail himself of every opportunity to utilize a new idea in his art. He relentlessly pursued another surgeon who was purported to have a formula for a very excellent ointment to be used as a wound dressing. It was only after two years of pestering that he finally persuaded the other to relinquish his secret, and when Paré did obtain the prescription, it was found to contain several ingredients, among which was boiled new-born puppies. To his credit is the improvement in the technic of amputations, and the use of the ligature as a substitute for the cautery. His ointment for gunshot wounds instead of boiling oil was one of the first steps in the rational treatment of those injuries. Malgaigne believes him to be the first to make mention of metastatic abscesses in the various organs following wound infection. He popularized the truss for hernia, and made the first disarticulation of the elbow-joint. In obstetrics he described podalic version, and induced labor in cases of uterine hemorrhage; he devised various appliances and procedures improving the practice of dentistry. An operation for cataract is given, but his link with the past is shown by the statement that it should only be performed at the waning of the moon. He was responsible for many advances in the art of medicine, swept away many superstitions, and popularized many valuable procedures.

His treatise on the mummy and the unicorn is an indication of the popular state of mind. Mummy was a resinous substance supposed to be obtained only from Egyptian mummies. Unicorns horn was extremely costly since it was considered an absolute preventative against poisoning, a piece of it dipped into any decoction rendering the drink harmless. Genuine unicorns horn commanded a fabulous price. Paré cast a bombshell into the camps of the entire medical fraternity when he declared that there was no proof that such an animal as an unicorn ever existed, and if such did, the horn was of no value.

His works include among others a treatise on gunshot wounds published in 1545; a work on podalic version in 1550; Wounds of the Head, and Anatomie Universelle in 1561; and a treatise on surgery published in 1564. Following epidemics he wrote in 1568 a set of works on plague, small-pox, and measles, and in 1573 in addition to two more works on surgery, his famous book dealing with "Monsters, Terrestial and Marine." In 1582 came the death blow to the charm-merchants in his work on mummy and unicorn's horn.

Francis Packard speaks of Paré as "one whose fame as a human benefactor will last until the race is no more, who from the humblest origin rose to high station solely as the result of his own genius . . . . his kindly, genial nature, coupled with his good sense . . . . a Frenchman writing scientific works with logical incisiveness and art . . . . his benevolence and charity to common soldiers. L'Estoile writes of him, "Thursday, twentieth of December, 1590, the Eve of Saint Thomas, died at Paris, in his own house, Master Ambroise Paré, surgeon to the king, aged eighty years, a learned man and the chief of his art; who, in spite of the times, had always talked and talked freely for peace and for the good of the people, that which made him as much loved by the good as he was wished evil and hated by the wicked."

HYPERTHYROIDISM*

A REVIEW OF 270 HOSPITAL RECORDS

EVELYN GRUHLKE MCLANE, A.B., M.D.†
Sleepy Eye, Minnesota

BETWEEN the dates of January 1, 1924, and January 1, 1930, 270 cases of hyperthyroidism were treated in the New Asbury Hospital, Minneapolis. Of this number 224 were treated surgically: 213 by thyroidectomy; 10 by ligations without subsequent thyroidectomies in this hospital; 1 by drainage of an abscess involving an adenoma.

Sex.—There was a marked predominance of females (83 per cent) over the males (17 per cent).

Age.—The ages of the males ranged from 18 to 64. Those of the females ranged from 11 to 93. The four oldest were 93, 72, 70 and 70. Fifty-three per cent of females were between 20 and 40 years. The following is a table of age distribution:

Age	Male	Per Cent	Female	Per Cent
11-20	3	6	4	2
20-30	10	23	60	27
31-40	16	35	58	26
41-50	4	8	35	16
51-60	11	24	46	20
61-70	2	4	19	8
71-93	0	....	2	1

The average age of the females was 39.4 years; of the males, 38.8 years.

Symptoms.—The following is a survey of the frequency of subjective symptoms. The most constant symptoms were: nervousness, palpitation, and loss of weight. It is to be noted that a tumor mass or enlargement of the neck was complained of in only one-third of the cases, but was palpable in 75 per cent.

	Per Cent
Nervousness	81
Palpitation	75
Loss of weight	48
Fatigue and weakness	27
Excessive perspiration	21
Tremor or unsteadiness	16
Increased appetite	15
Dyspnea	14
Abdominal cramps	12
Choking sensations	8
Edema of feet and ankles	7
Cough	6
Sensations of heat waves	6
Decreased appetite	5
Nausea, with or without emesis	5
Diarrhea, periodic	5
Decreased menstrual flow	3
Insomnia	3
Mania	2
Epistaxis	2
Generalized pruritis	2
Headaches	2

Other complaints appearing only once were: backache, swollen lids, dizziness, diplopia.

Physical Findings.—Order of frequency of physical findings was as follows:

	Per Cent
Palpable enlargement of thyroid	75
Tremors	70
Heart murmur	35
Exophthalmos	28
Lid lag	13
Nystagmus	10
Increased reflexes	10

Pulse pressure was generally high. The diastolic readings remained about normal, while the systolic were consistently higher than the usual findings. The average systolic blood pressure on entrance was 146, and the average diastolic was 76, giving an average pulse pressure of 70. The highest blood pressure, both in systolic and diastolic was 214/110 in a female of sixty years. In no case was the systolic reading below 100.

The average body weight among the males was 140 pounds, and among the females 122 pounds. The lowest weight of the males was 115 pounds, and of the females was 70, the latter in a woman of 37 years. The highest weight of this group of patients was 215 pounds in a female. Twelve per cent of the females were below 100 pounds.

Pre-Operative Treatment.—In reviewing the

*Presented May 1, 1930, before the Minneapolis Surgical Society by invitation after having been granted second prize in the Surgical Society Essay Contest.

†Formerly interne at the New Asbury Hospital, Minneapolis.

pre-operative treatment of these cases six (2.5 per cent) were found to have had previous operative procedures for hyperthyroidism; five had had thyroidectomies one to four years previously; one had had a ligation fifteen years before.

The medical preparation for surgery was limited to the use of only a few forms of medication:

Eighty-five per cent were given Lugol's solution—10-20 m. t.i.d.

Twenty-three per cent were given Luminal—grs. 1 to 1.5 in the evening.

Twenty per cent were given bromides, usually as triple bromides, and in dosage of grs. 15, t.i.d. or q.i.d.

Thirteen per cent were given some form of digitalis.

Bed rest was given to all those prepared in the hospital and to many who were prepared in the home. The average time for pre-operative preparation was two to three weeks. Some few cases received no formal preparation, but I noted that in nearly all of this group the symptoms were not intense, and also observed that where studies were made by the pathologist that the report was usually adenoma.

In preparation of those patients with the very highest basal metabolic readings, the following combination of rest and medication for two to three weeks seemed to be the most common:

Lugol's .....t.i.d.
Luminal..... ..... in the evening
Triple Bromides.....t.i.d.
Bed Rest.

One patient was given the Crile method preceding a double ligation.

Basal Metabolic Rates.—The highest reading of this series was so high that the patient was in the hospital and under the above treatment for one week before it was low enough to be registered on the graph, and then it was 128 (plus). No later record was available, but a thyroidectomy was accomplished and the patient made a good recovery.

The next highest rate was plus 98. This was reduced to a plus 45 in three weeks of this treatment. The two next highest were plus 95 each, one being reduced to plus 42 in three weeks and the other to a plus 45 in two and one-half weeks. Another of plus 93 was reduced to plus 55 in two and one-half weeks, without the bromides.

Examples of less extreme readings are:

Rate of plus 66 reduced to plus 22 in two weeks;
Rate of plus 44 reduced to plus 19 in two weeks, no bromides;
Rate of plus 50 reduced to plus 19 in two and one-half weeks, no bromides;
Rate of plus 39 reduced to plus 12 in two weeks, no bromides or luminal.

Many charts had as high as four basal metabolic readings during the pre-operative records. Some charts had only one basal reading, and a few had none, but these latter comprised a small enough group so as not to interfere with averages.

Seventy-five per cent of the basal metabolic rates went down under this treatment.

Twenty-five per cent either increased slightly or did not change.

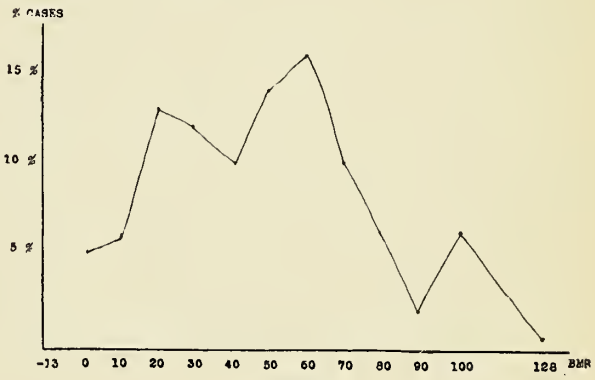

Figure 1.

Figure 1 is a graph of the distribution of the basal rates. The lowest was a minus 13, but this and other cases of minus rates were showing clinical symptoms of hyperthyroidism.

Post-Operative Treatment. — Post-operative treatment was very similar in type to the pre-operative:

Seventy-three per cent received Lugol's; 15 per cent were given luminal; 12 per cent were given some form of digitalis.

Otherwise the care was as is found in any group of post-operative cases. Glucose by rectum was given frequently. Patients remained in sitting posture three to five days. The treatment, postoperative, could not be traced for longer than the hospital stay, so cannot be reviewed completely. Most of the uncomplicated cases remained in the hospital seven to ten days following operation.

Complications.—The complications may be divided into a very few groups. About 9 per cent of the patients had cardiac complications following operation. Fibrillation was most common and in some cases there was no other finding than an exaggerated tachycardia, causing the patient fear and discomfort. The next most frequent group of complications was respiratory infections. Bronchitis was the most frequent, coryza next, and one case was recorded as broncho-pneumonia. These respiratory infections occurred in 5 per cent of the cases, one-fourth following local anesthesia, and three-fourths after general anesthesia. An infected wound was present in 3 per cent of the cases. In two instances the patient had been under treatment for diabetes for some time preceding thyroidectomy. No ill effects were noted after operation that could be attributed to the diabetes, these patients being under careful insulin management continuously by experts in care of diabetes.

Anesthesia.—The following is a calculation of the frequency of the use of the various anesthetics: 27 per cent novocaine plus nitrous oxide; 29 per cent nitrous oxide, or nitrous oxide plus ether; 44 per cent novocaine.

Post-Operative Condition.—No post-operative check on the condition of the patients could be made later than the date of leaving the hospital. Basal rates taken after operation were not available. However, the condition of the pulse and respiratory rates at the time of discharge from the hospital were as follows:

Seventy-four per cent showed moderate to marked lowering of pulse and respiratory rates; 19 per cent showed little change; 7 per cent showed a slight increase; none were marked.

The general condition of all seemed improved with the exception of two cases.

Pathology.—Studies and reports, either gross or microscopic, or both, were made by the pathologist in 74 per cent of thyroidectomy cases. Only one record of malignancy was found and this was reported to be open to question.

Personnel.—The work on this group of cases was done by sixty-one physicians, both medical and surgical. Of the operated cases, one-half was done by nine members of the staff, and the other half was divided among forty members.

Mortality.—Out of the 224 operative cases there were five deaths, a post-operative mortality rate of 2.3 per cent. In addition, two patients died without thyroid surgery. One who had marked hyperthyroid symptoms died following a cholecystostomy. The other entered the hospital in a toxic state and died the same day, autopsy showing cirrhosis of the liver and adenoma of the thyroid. Of the thyroid post-operative deaths, one was a male and four were females.

A brief review of the five fatal cases follows:

Case 1.—Female, age not given, weight 95 pounds.

Symptoms—Extreme nervousness for one year; palpitation and nausea, 3 months; very poor appetite.

Physical Findings—Lid lag, small mass in neck, tremor, tachycardia (108), poor tissue turgor. No. B.M.R. record.

Pre-operative Treatment—Digifolin, Lugol's (uncertain time).

Operation—Thyroidectomy.

Post-operative Treatment—Digifolin, Lugol's, intravenous saline, proctoclysis.

Complication—Auricular fibrillation. Death fifth post-operative day. No autopsy.

Case 2.—Female, aged 38, weight 215 pounds.

Symptoms—Nervousness, insomnia, weakness, excessive perspiration, and extremely active appetite for one year. Palpitation for five years. Palpitation started when patient took thyroid to reduce.

Physical Findings—Small mass in neck, tremor, obesity. Blood pressure 160/90. B.M.R. plus 43 on entrance, and after two weeks' treatment plus 25.

Pre-operative Treatment—Lugol's m X t.i.d., luminal at night.

Operation—Thyroidectomy.

Complication—Died within few hours after operation; extreme tachycardia, shock, hemorrhage into wound, and collapse of trachea. No autopsy.

Case 3.—Female, age 31.

Symptoms—Palpitation, loss of weight, visual disturbances, markedly increased appetite, and edema of the feet and ankles.

Physcial Findings—Exophthalmos, lid lag, nervousness, B.M.R. plus 20.

Pre-operative Treatment—Lugol's m X t.i.d., luminal at night, triple bromides t.i.d. Eight days' preparation.

Operation—Thyroidectomy started, but just as muscles were separated and the right upper pole grasped, the patient breathed strangely and died.

Autopsy—Air embolism (massive collapse of the lungs secondary to artificial respiration).

Case 4.—Female, age 42.

Symptoms—Dyspnea for four months, palpitation and nervousness for three months, vomiting for one week, with loss of weight.

Physical Findings—Mass in neck, exophthalmos. B.M.R. plus 77.

Pre-operative Treatment—Patient had taken Lugol's continuously for six weeks before entrance to hospital. After entering she was treated with bed rest, triple bromides, morphine sulphate, and hyoscine for seventeen days. Patient became steadily worse, and was

finally taken to operating room in semi-conscious condition.

Operation—Double ligation.

Complication—Died first day in apparent collapse. No autopsy. Toxic myocardium.

Case 5.—Male, age 64, weight 125 pounds.

Symptoms—Nervousness, palpitation, increased appetite two years.

Physical Findings—Exophthalmos, mass in neck, B.M.R. plus 41, and after two weeks' treatment increased to 52.

Pre-operative Treatment—Lugol's, luminal.

Operation—Thyroidectomy.

Complication—Died first day in shock. No autopsy.

SUMMARY

In reviewing this series of 270 hyperthyroid cases, treated in a private hospital by 60 members of the staff, it was found that 75 per cent responded by reduction of basal metabolic rate, to a treatment consisting chiefly of Lugol's solution, luminal at night, and triple bromides, this being given over a period of two to three weeks. Females predominated very markedly in number, individual weights were somewhat low, and systolic blood pressure somewhat high.

A remarkable standardization of treatment is shown with excellent results. The mortality under surgical treatment of 2.3 per cent under the conditions described in this paper, demonstrates the progress made in the treatment of this once dreaded disease.

DESICCATED OVARIAN PREPARATIONS FOR ORAL ADMINISTRATION OMITTED FROM N. N. R.

The Council on Pharmacy and Chemistry reports that, believing that the available evidence fails to prove the therapeutic value of desiccated ovarian preparations composed of all or a part of the ovary for administration by mouth, it decided to omit all such preparations with the close of 1929 unless new evidence should meanwhile develop making other action justifiable. No acceptable evidence for the value of desiccated ovarian preparations for oral administration having become available, the Council confirmed its decision and omitted all desiccated ovary preparations for oral administration from New and Non-official Remedies, 1930. (Jour. A. M. A., June 21, 1930, p. 1997.)

GOLD SODIUM THIOSULPHATE IN LUPUS ERYTHEMATOSUS

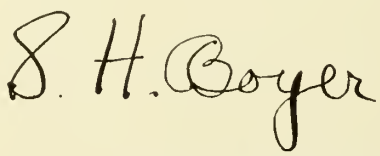
Gold salts have provided an effective method of treating lupus erythematosus. The treatment usually definitely improves the condition and often gets entirely rid of it. Gold sodium thiosulphate is the salt generally used in the United States. The initial dose is 10 mg. dissolved in 2 c.c. of sterile distilled water, given intravenously. If this is well tolerated, the second dose is 25 mg. given from five to seven days later. After this the dose is repeated at weekly intervals. Doses up to 50 mg. may be administered and they have been as satisfactory as doses of 100 mg. Occasionally severe reactions result from the use of the drug. The drug should not be pushed when symptoms occur from it. (Jour. A. M. A., May 24, 1930, p. 1715.)

President's Letter

For reasons not difficult to understand, expert medical testimony as adduced in our courts is looked upon with considerable contempt by the laity, and with a feeling of exasperation by the medical profession. The legal profession appears to be quite complacent in regard to it, evidently considering the present methods of its application quite suitable to their needs.

Regardless of how medical testimony may be considered in general, the phase dealing with crime and insanity in particular appears to have aroused the greatest criticism on the part of the public and of the medical profession.

The Committee on Medico-Legal Affairs of the State Association made a careful study of this subject during the past year. An excerpt from its report to the House of Delegates follows:



"It has been the belief of the Committee on Medico-Legal Affairs that the time is ripe in the state of Minnesota for some constructive legislation along the lines of expert testimony, particularly with reference to the mental status of criminals being brought to trial. It has been felt desirable to have the initiation of such legislation as in the state of Massachusetts, whereby the matter of the sanity of criminals is not brought before a jury for decision, but is determined by a commission or board appointed for that purpose, and that the matter of the sanity of the criminal should never be left to a lay jury to determine. In view of the fact that this involves an amendment to the constitution of the state of Minnesota, it is impossible to make any rapid progress in the enactment of such legislation. It is felt by this committee that such legislation should primarily be enacted through the legal profession, with the moral support of the medical profession of the state."

Whether or not the legal profession will become actively interested in such constructive legislation cannot be stated at the present time. In our opinion it is a duty incumbent upon them. The dictates of reason would suggest that *no* technical question should be decided by a lay jury.

The purpose of courts of justice is to learn and establish the truth. Judges and attorneys at the bar are, after all, merely instruments of legal interpretation and procedure, just as we of the medical profession are but instruments of healing. They are not expected to possess more than general knowledge on subjects outside of their special field of activity. The work of lawyers consists, in part at least, in gathering supposedly reliable information for presentation in court. Therein rests the reason for the expert witness. The latter is presumably accurately and scientifically informed in his particular field of training, whatever it may be. He is therefore called upon for the purpose of *enlightening the court* in regard to matters concerning which he has special knowledge and for the purpose of expressing an opinion based upon such knowledge.

Such being the fact it would seem that medical witnesses themselves could do a great deal toward improving the status of the medical expert. The spirit of scientific accuracy with its totally impersonal attitude should be cultivated. There are increasing instances in which the doctors called upon opposite sides of trial cases quietly get together and freely discuss the medical phases entering into such cases. Their attitude toward each other is one of candor and confidence. Their attitude toward the case in court becomes impersonal and unbiased. Their discussion is scientific and analytical. Such expert medical witnesses are interested not at all in one side or the other. They care not an iota which lawyer wins. They are vitally interested in arriving at a common and rational conclusion. Having reached a reasonable understanding they are prepared to appear on the witness stand and submit information and opinions which are truthful and not in conflict. As the purpose of such *ex cathedra* discussions is to advance honesty and truth it is impossible to see wherein any court could offer objection. Conceivably opposing counsel might not be so favorably disposed.

Manifestly the success of such conferences depends upon the complete trust and confidence of the conferees in each other. Happily, as the medical profession advances in knowledge, widens its field of contacts and takes on an increasingly broader outlook upon life, its members develop a greater respect for each other's attainments and integrity.

President,
Minnesota State Medical Association.

BOEHLER'S METHOD OF TREATMENT OF FRACTURES

At the meeting of the Minnesota State Medical Association, in Duluth, Dr. Lorenz Boehler, of Vienna, gave a presentation of his treatment of fractures as conducted at his clinic. The large attendance at his lecture was evidence of the general practitioner's desire for more information on the subject. Owing to the fact that machinery, with all its hazards, is used on the farms so much more than formerly, and that modern highways, with rapid transportation, increase hazards, the staffs of hospitals in rural communities are called on to treat increasing numbers of types of fractures that formerly were seen chiefly in the industrial centers.

The establishment of Doctor Boehler's fracture clinic was brought about through his conviction that fractures demand special treatment and, therefore, that carefully planned and selected equipment is essential. By emphasizing the economic importance of the patient with a fracture he was able to induce certain insurance companies to establish the clinic solely for the treatment of fractures.

Because Doctor Boehler's methods are ingenious and unusual, the underlying principles may not be generally grasped. Traction is the keynote of his treatment, and is made possible by inserting rustless steel pins through the fragments and thus providing skeletal traction. The fracture is reduced, and while the position of the fragments is maintained, a split plaster-of Paris cast is applied and the pins are locked in its substance. Elevation of the part prevents subsequent swelling, which, if allowed to occur, would necessitate removal of the cast and loss of position. Local anesthesia simplifies reduction in certain types of fracture, and early use of the part prevents the necessity of a prolonged course of treatment with physical therapy, after union is obtained.

Briefly, Doctor Boehler's method consists of reduction by skeletal traction, elevation of the extremity to prevent swelling, and early motion of the parts involved.

M. S. H.

COOPERATION WITH THE PURPLE CROSS

It may or may not be appropriate that entrance to this world should be certified by the physician and exodus by the undertaker. It is not generally known, however, that according to the law in this state the undertaker is required to furnish a death certificate filled out and signed by the last physician in attendance, before a burial permit is allowed. This law went into effect several years ago and there might be room for argument whether the entire responsibility for certification should in justice be placed on

the undertaker. The law being as it is, there is every reason why the physician should cooperate in every way in filling out his part of the certificate. We are informed that 95 per cent of physicians promptly do their part. There are, of course, exceptions. One physician, we are informed, refused to be bothered because it was Sunday. This necessitated a second trip on the part of the undertaker, and, of course, caused inconvenience and hard feeling. It is almost inconceivable that any physician should have taken such an attitude.

The Purple Cross is the insignia adopted at the time of the World War by the funeral directors of the country, more commonly known as undertakers. Various localities, including Minneapolis and Saint Paul, have a Purple Cross Club composed of the local funeral directors.

The attention of officials of the State Medical Association has been called to this joint obligation of undertaker and physician, with the idea that better understanding will result. Both professions serve the public and it is in the interests of better service that attention is called to the need for 100 per cent cooperation.

MEDICAL MEETINGS

That the medical profession of Minnesota is alive is evidenced by the unusual opportunities recently afforded and about to be offered to physicians in the state. The A. M. A. meeting in Minneapolis in June, 1928, the Congress of the College of Physicians in the same city last February, and the Kidney Symposium at the University last July, are all fresh in our minds.

At a time when we were feeling considerable depression over the loss of three of our outstanding professors at the medical school, Drs. Schlutz, Adair and Scammon, along came the Kidney Symposium, a stupendous undertaking involving the assembling of world authorities on the kidney, conceived and accomplished by the energy of Professor Berglund.

In spite of the almost intolerable hot spell which outlasted the symposium, the meetings were well attended. Besides the many visitors, a number of local physicians attended the majority of sessions, and many returned frequently for another taste of what was for them a rather rich diet.

The first week of the two-week session was devoted to addresses and round table discussions of fundamental phases of kidney study—the growth, development and function of kidney structures. This was contributed to by such men as Drs. Carlson of Chicago, Haber of Michigan, Marshall of Johns Hopkins, Richards of Pennsylvania, White of Saint Louis, Scammon, Jackson and Bieter of Minnesota. Functional phases of the kidney were presented by Drs. Hannon, Rockefeller Institute, Rehberg of Copenhagen, Magath and Rowntree of Rochester, and Diehl, McKinlay and Bieter of Minnesota. Drs. Robinson of Sprague Memorial, Seeter of Hastings, Barker of Chicago and Berglund of Minnesota discussed the subject of blood proteins, chlorides and water balance. Dr. Bell of Minnesota, who has directed so much of his attention to kidney pathology, gave his well known views.

The second week of the symposium was spent in discussing pathological aspects of the kidney and treatment. This phase of the subject was contributed largely by Drs. Volhard of Frankford-on-the-Main, Snapper of Amsterdam, Longcope of Johns Hopkins and Fahr of the University. Eye background changes were presented by Drs. Foshberg, Friedenwald and Wagner. The question of whether nephrosis is or is not was not finally settled, but Epstein's views were listened to attentively.

And now comes the Inter-State Assembly to Minneapolis in October. The organization originated in this section of the country as the Tri-State Medical Association, but has rapidly grown in size and national importance until attendance has rivaled that at the A. M. A. meetings. Its activities have been and should continue to be strictly devoted to post-graduate education, the program being for the most part contributed by professors or associate professors of medical schools in the United States, Canada and abroad. Members of the profession of national and international reputation will contribute to the lengthy and interesting program to be offered. This opportunity should not be missed.

COFFEY-HUMBER METHOD FOR CANCER

The remarkable publicity accompanying the introduction of the Coffey-Humber method for the treatment of cancer passed briefly into a quiet phase, leaped upward with the eastward jaunt to the congressional hearing, again became quiescent for a few weeks, and burst forth into a Sunday supplement feature. In the meantime pathologists, surgeons and other cognoscenti who have investigated the method express nothing but profound disappointment with both the clinical and the pathologic results. (Jour. A. M. A., May 3, 1930, p. 1410.)

OF GENERAL INTEREST

Dr. G. D. Guilbert, formerly of waterville, is now located at Maynard, Minnesota.

Dr. L. F. Woodworth, of Le Sueur Center, is taking post-graduate work at Iowa University.

Dr. Edward Gibbs has recently become associated in practice with Dr. Charles N. Hensel of Saint Paul.

Dr. W. C. Ehmke, of Willow River, has returned to his practice following a vacation trip in Southern Minnesota.

Dr. J. J. Kolars, of Le Sueur Center, is taking a course at the Post-Graduate School of Surgical Technique, Chicago.

Dr. C. R. Christenson, formerly of Starbuck, Minnesota, opened offices at 404-406 Wilmac Building, Minneapolis, July 1.

John A. Cameron, Jr., son of Dr. John A. Cameron, Saint Paul, died August 18, 1930, following an automobile accident the previous day.

Dr. H. K. Helseth is practicing at Appleton, Minnesota, where he located following a year's interneship at St. Barnabas Hospital, Minneapolis.

Dr. Eugene Edward Scott has opened an office at 814 Lowry Medical Arts Building, Saint Paul, for the practice of general surgery and proctology.

Dr. R. Wayne Esperson has established a practice in Bend, Oregon, following the completion of his interneship at the Miller Hospital, Saint Paul.

Dr. Valorus F. Lang, of Minneapolis, after completing his interneship at Ancker Hospital, Saint Paul, is taking a fellowship at the Mayo Foundation.

Dr. Elmer Wahlberg is engaged in general practice at Isle, Minnesota. Dr. Wahlberg completed his interneship this year at the Miller Hospital, Saint Paul.

Dr. Elmer A. Smisek is now associated in practice with Dr. Thomas Gratzek of Saint Paul. Dr. Smisek completed his interneship at the Miller Hospital this spring.

Dr. A. F. Hunte, formerly of Truman, Minnesota, is now located at the San Carlos Indian Agency, Rice, Arizona, where he has accepted an appointment as physician.

Dr. Marland Williams, after completing his internship at Bethesda Hospital, Saint Paul, has taken over the practice of the late Dr. Connolly at Cannon Falls, Minnesota.

Dr. Lee R. Alderson, Rochester, after serving his interneship in the Indiana University Hospital last year, is now majoring in pediatrics at the Mayo Foundation, Rochester.

Dr. Raymond B. Allen, Minneapolis, has severed his connection with the Northwest Clinic of Minot, North Dakota, and is majoring in urology at the Mayo Foundation, Rochester.

Dr. John R. Meade, Saint Paul, is taking a post-graduate fellowship in the Mayo Foundation, Rochester, having served the past year as interne at St. Joseph's Hospital, Saint Paul.

Dr. Leslie L. Nunn has opened offices at 521 Arts Building, Vancouver, Washington, for the practice of general surgery. Dr. Nunn was formerly associated with the Mayo Clinic, Rochester.

Dr. L. R. Peck, graduate of the University of Minnesota, 1929, has established a practice at Hastings and Hampton, Minnesota. Dr. Peck was an interne at St. Barnabas Hospital, Minneapolis, the past year.

Dr. Philip Bray and Dr. Donald Dukelow, who recently completed their interneship at Miller Hospital, Saint Paul, are taking fellowships in pediatrics and dermatology, respectively, at the Minneapolis General Hospital.

Dr. D. C. Wirtz, who was resident physician of the Gillette State Hospital for Crippled Children, from July 1, 1929, to June 30, 1930, has recently opened offices at 414-415 Southern Surety Building, Des Moines, Iowa, doing general practice and orthopedic surgery.

Dr. H. R. Anderson, who interned at the N. P. B. A. Hospital from July, 1929, to July, 1930, has opened an office at Twenty-seventh Avenue and Lake Street, Minneapolis. He is engaged in general practice in the view to specializing in surgery later.

Dr. M. H. Siefert, who interned at the N. P. B. A. Hospital from June 1, 1929, to June 1, 1930, was married to Miss Laura Dupont on May 31, 1930. Dr. Siefert has opened his office at Excelsior, Minnesota, where he is engaged in general practice.

Dr. Lorenz Boehler, of Vienna, was in Rochester July 17 and was entertained at a dinner given by the Olmsted County Medical Society, seventy guests from Rochester and vicinity being present. In the evening Dr. Böhler gave a lecture before a large audience on his new methods in the treatment of fractures.

Invitations to the dinner and lecture were sent out to members of the State Society in the First Councilor District.

THE BAKER BALLYHOO

Norman Baker, the high-pressure gentleman at Muscatine, Iowa, who has recently invaded the medical field with two quack cancer cures—those of Ozias and Hoxsey—continues to get publicity. This in addition to the very good job that he does over his own radio station, KTNT. Recently newspaper accounts have appeared stating that Baker had claimed that an attempt had been made on his life and that an attempt had been made to blow up his radio station. These reports were not confirmed. The only other newspaper items that have been noted regarding Baker are the reports of cancer victims who have died following the Baker Institute "treatments." (Jour. A. M. A., April 26, 1930, p. 1430.)

A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION

"Summer Complaints"

"The growls one hears in the good old summer-time!" sighs the bulletin of the Brooklyn Medical Society of the County of Kings. Interesting but astonishing reading for medical readers in Minnesota.

The aftermath of a hot dry summer plus a state medical meeting is certainly not general conviction that everything in the world is wrong with medicine in Minnesota.

The County of Kings commentator picks just a few of the complaints from the din about his ears. "The costs are too high . . . the rewards are too low . . . medical men back-bite . . . the specialist becomes wealthy in short order . . . the child of the generalist goes without shoes . . . hospitals are too few, too large, too elaborate, too congested . . . and cults are anathema or life savers as the mood directs."

He should come to Minnesota. In Minnesota "summer complaint" occurs only as a name in old fashioned medical literature. Otherwise there is a sound, unalterable conviction of the dignity and worth of a free, independent, solidly organized medical profession—and complaints are chiefly conspicuous by their absence, at least in the environs of medical society executives and committee chairmen.

"As a matter of fact," asserts the County of Kings commentator sturdily, "the medical profession is not so bad. It does do its sincere bit of work every day, every hour."

It does in Minnesota, Mr. County of Kings.

The Best of a Bad Bargain

"The ethical medical profession did its utmost to prevent the passage of the Porter Narcotic Bill.

"This sort of legislation was unnecessary, uncalled for, and superfluous in every respect. Further, it is of a piece with the menacing tendencies toward bureaucratic control, that, if unchecked, will soon work the destruction of our democracy.

"Any good that is accomplished by this new narcotic drug legislation will depend upon the wisdom of the president in the selection of the Commissioner of Narcotics and the wisdom of the Secretary of the Treasury in appointing a deputy commissioner. That these two officials should be chosen from the ethical medical profession stands to reason, from the point of view of human welfare. Blanketing as it does all drug usage from import and manufacture to distribution through many channels, it would seem that this statute gives the federal government a large hunk upon which to chew. To put it mildly, the situation is so complicated that it offers endless opportunities for leakage. The chemist, the doctor, the veterinarian, the dentist, and possible commercial contingencies are all to be considered. These separate and several interests may sometimes be analogous but they are scarcely coincident. It can be disputed with justice that a physician need not be appointed to handle commercial problems, and certainly there is enough lay dictation of medicine on hand now to save the medical profession from having its needs and requirements passed upon by somebody who knows nothing at all about medicine, though possibly a terrible amount about business."—*Illinois Medical Journal*, July, 1930.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 10:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and St. Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of September will be as follows:

September 3—Bowel Obstruction.
September 9—Trench Mouth.
September 17—Cause of Flatulence.
September 24—Acne.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

The Northern Minnesota Medical Association will hold its annual meeting at Moorhead, Minnesota, Friday and Saturday, September 19 and 20, 1930.

These meetings are always well attended, and the usual attractive program is being developed for the occasion. The complete program is not yet formulated, but will include the following speakers:

Dr. Wm. Boyd, Professor of Pathology, University of Manitoba, Winnipeg—"Rheumatic Disease of the Heart."

Dr. P. F. Eckman of Duluth, Minnesota—"The Classification of Purpura."

Dr. W. C. Alvarez, Rochester, Minnesota—"Diagnosis of Gastrointestinal Disease."

Dr. H. W. Woltman, Rochester, Minnesota—"The More Common Diseases of the Spinal Cord."

Dr. E. T. Evans, Minneapolis, Minnesota—"Orthopedic Care of Poliomyelitis."

Dr. E. W. Humphrey, Moorhead, Minnesota—"The Open Treatment of Fracture."

Dr. Emil Geist, Minneapolis, Minnesota—Boehler's Treatment of Fracture."

Dr. James B. Carey, Minneapolis, Minnesota—Subject to be announced.

Dr. R. S. Allison, Minneapolis, Minnesota—"Bone Tumors."

Dr. Edgar Herrmann, Saint Paul, Minnesota—"Malaria and the Roman Empire."

Dr. C. W. Schougge, Bismarck, North Dakota—"Intestinal Obstruction."

Dr. M. A. Shillington, Saint Paul, Minnesota—"Spastic Constipation and Its Treatment."

Dr. Harold Hullsiek, Saint Paul, Minnesota—"Benign Polyps of the Colon and Their Relation to Cancer."

Dr. R. S. Ylvisaker, Fergus Falls, Minnesota—"Functional Disturbances of the Bowels."

Dr. W. H. Long, Fargo, North Dakota—"Consideration in the Management of Secondary Anemia."

Dr. F. E. B. Foley, St. Paul, Minnesota—"Plastic Operation of the Renal Pelvis for Hydronephrosis."

Dr. Wm. Baillie, Fargo, North Dakota—"Some Indications for Urologic Examination."

Dr. B. J. Branton, Willmar, Minnesota—"Ectopic Gestation."

Dr. M. H. Nathanson, Minneapolis—"Diagnosis and Management of Coronary Arterial Disease."

Other speakers on the program will be: Dr. J. A. Myers, Minneapolis; Dr. Max Hoffman, Saint Paul; Dr. A. Gibson, Winnipeg; Dr. J. D. Adamson, Winnipeg, and Dr. J. K. Anderson, Minneapolis.

The banquet is to be held Friday evening, September 19, 1930, and Dr. H. C. Cooney of Princeton, Minnesota, as president of the Association, will give his annual address. An address on "Publicity" is also to be given by Mr. Banshoof of Detroit Lakes.

The complete program will be mailed about September 1.

INTERNATIONAL ASSEMBLY OF THE INTER-STATE POSTGRADUATE MEDICAL ASSOCIATION OF NORTH AMERICA

Among the outstanding medical meetings scheduled for the fall is the Inter-State Postgraduate meeting, October 20 to 24, inclusive, at the Minneapolis Auditorium.

In addition to prominent members of the profession from Canada and the United States, the program includes the following from abroad:

Dr. Paul Clairmont, Head of the Department of Surgery at the University of Zurich, Switzerland.

Mr. John M. C. Fraser, Regius Professor of Clinical Surgery at the University of Edinburgh, Scotland.

Dr. Edmund Gros of the American Hospital at Paris, France.

Dr. Emile de Grosz, Professor of Ophthalmology at the University of Budapest, Hungary.

Mr. John Stephen Lewis, London.

Dr. Ferdinand Sauerbruch, Professor of Surgery at the University of Berlin, Germany.

Mr. A. H. M. J. Van Rooy, Professor of Obstetrics and Gynecology, University of Amsterdam, Holland.

Dr. Henry Wade, Surgeon, Royal Infirmary of Edinburgh, Scotland.

Dr. William D. Haggard, Nashville, Tennessee, is President of the Association; Dr. George W. Crile, Chairman of the Program Committee; Dr. William B. Peck, Freeport, Illinois, Managing Director; and Dr. Edwin Henes, Jr., Milwaukee, the Executive Secretary.

AMERICAN ASSOCIATION FOR THE STUDY OF GOITER

At the recent meeting of the American Association for the Study of Goiter at Seattle, Washington, Doctor William F. Rienhoff, Jr., of Johns Hopkins University, Baltimore, Maryland, received the annual award of $300 for the best essay dealing with the goiter problem. Doctors O. P. Kimball, of Cleveland, Ohio, and E. P. and D. R. McCullagh, Cleveland Clinic Foundation, Cleveland, Ohio, and Robert P. Ball, of the University of Louisville, received honorable mention.

CONSULTATION BUREAU

WM. A. O'BRIEN, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question*—Female nurse, age twenty-seven, weight 105 pounds. Past history of chorea in childhood and exposure to tuberculous patients while in training. Family history for tuberculosis negative. Present complaint dates back to summer of 1925 when she had hemoptysis of a few ounces of bright red blood and slight hemoptysis for several days following. She has had two or more similar afebrile attacks every year since. Excitement or exertion seems to be a factor in bringing on some of the attacks. Last March she coughed up bright red blood, one to four ounces, several times a day for five to seven days; feels better after hemoptysis. She has been losing strength since this last attack. In the last few days she has had two attacks of hemoptysis. Since January 1, there has been increased dyspnea and cough on exertion, some sub-sternal oppression, weakness, and slight loss of weight. In summer of 1928, I tapped her left chest and removed 1,000 c.c. of straw colored fluid which was negative for tubercle bacilli by guinea pig inoculation. Stereoscopic films of the chest four years ago were negative for tuberculosis. *X*-ray and chest examination negative since for tuberculosis.

   I have diagnosed her case as combined mitral stenosis and regurgitation on account of harsh, rumbling murmur ending in loud first sound at apex, slight left ventricular enlargement by *x*-ray; an apex beat as if a jet of liquid were pushed against the hand (no palpable thrill); a reduplication or rather gallop rhythm of P2 in third left interspace and normal blood pressure. What are possibilities in her case? Would mitral stenosis give such attacks of repeated hemoptysis, last attack lasting from four to six days? Can digitalis be safely given in such attacks?

   Answer—You have apparently ruled out pulmonary tuberculosis as the cause of your patient's hemoptysis. Mitral heart disease is a frequent sole cause of this condition. It is due to marked passive congestion secondary to a dilated left auricle and a congested pulmonary circulation or passive congestion combined with single or multiple infarction. Infarcts of the lungs occur frequently in connection with passive congestion. You state that the left ventricle is slightly enlarged by *x*-ray examination. Was this a six-foot plate or was it a flat plate in which a search for tuberculosis was being made? Enlargement of the left ventricle may occur in conjunction with mitral stenosis and regurgitation, especially when the regurgitant phase is more marked than the stenosis. Other causes would be associated hypertension, involvement of the aortic valve with a defect, or pericardial adhesions as a result of rheumatic infection of the pericardial sac. You did not state the temperature of your patient. Such a picture as you have described might be associated with active reinfection of the valves and mural endocardium.

   The patient is apparently decompensated and should be treated for myocardial insufficiency. The use of digitalis is not contraindicated. It is the only known way of treating such a patient with hemoptysis.

2. *Question*—A patient who has been injured comes to my office for care. I find it necessary to take *x*-ray pictures to aid me in making a proper diagnosis. The patient pays for his care and for the *x*-ray examination. To whom do the *x*-ray pictures belong?

   Answer—To the owner of the apparatus. In your case they belong to you. *X*-ray films are only a medium through which we gain certain information. They might be compared to a stethoscope or to a thermometer. If the examination was conducted in a hospital by you and the hospital owned the apparatus, the *x*-ray films would belong to the institution.

3. *Question*—A young man had been injured the night previously in an automobile accident, and he suffered several rather deep lacerations. These were cared for in the ordinary manner with thorough cleansing of the wounds with tincture of iodin and alcohol. After the wounds were dressed I told the patient that I would give him some tetanus antitoxin. He refused saying that he would rather take his chances with lockjaw than to take the serum. Should this patient develop tetanus, am I liable?

   Answer—No, you are not liable. It probably would be better in a case like this to obtain a written statement from the patient to that effect. Institutions use a regular form for this purpose, when patients sign out before the treatment is completed and against the advice of the physician. However, it probably would not make any difference in your case if witnesses were present.

4. *Question*—What is the cause and treatment of achylia?

   Answer—Achylia literally means absence of chyle which would include both pepsin and hydrochloric acid. In most instances achylia means absence of acid because the enzymes are not searched for. It is possible to have the enzymes present and the acid absent. Achylia occurs in apparently normal individuals, with advancing years, in certain families and in connection with several diseases, notably carcinoma of the stomach and pernicious anemia. The probable cause is atrophy of the glands of the stomach although it may be temporary depression. It is assumed that the condition follows chronic gastritis although this is problematic.

   The treatment of achylia is usually not started unless there are symptoms. Diarrhea is a fairly common complaint in patients with this disorder. When diarrhea or other symptoms develop, a bland, non-irritating diet is advised and dilute hydrochloric acid is given before meals.

OBITUARY

W. A. Frost, Ph.G.
1854-1930

Mr. W. A. Frost, one of the best known pharmacists in the state and one of the veterans in the profession, died August 12, 1930, at his home in Saint Paul, of heart trouble which had incapacitated him for a few weeks.

Mr. Frost was born in St. John, New Brunswick, April 11, 1854, and came to the States when sixteen years old in the employ of Caswell, Hazard and Company, the firm name later being changed to Caswell, Massey and Company.

He received his training in pharmacy at the New York College of Pharmacy, which later became incorporated with Columbia University. Upon leaving New York he came west and went into business under the firm name of Carlson Brothers and Frost at Willmar, Minnesota.

Several years later Mr. Frost came to Saint Paul and located under the firm name of Clark and Frost at Third and Robert Streets, when Third Street was the main business street of the city. When business left Third Street he moved to Sixth and Minnesota, where he was established until about 1890, when he moved to the present location at Western and Selby Avenues.

For twelve years Mr. Frost was president of the State Board of Pharmacy and for several years lectured at the University College of Pharmacy. He was elected honorary president of the American Pharmaceutical Association, an honor granted yearly to members who have been pharmacists for many years and whose practice in the service has been "distinctly professional." Many years ago he served as second vice president of the national organization and for three years was a member of the executive council.

Mr. Frost was a thirty-second degree Mason, a Scottish Rite Mason and for many years treasurer of the Summit Lodge and the building fund of that lodge.

Mr. Frost lived at 748 Goodrich Avenue, Saint Paul, and is survived by his widow and a niece, Mrs. Edward Schons.

Mr. Frost had a host of friends in the medical profession. Included among his friends were a number of the oldest physicians in Saint Paul, to whom he had lectured on pharmacy in the early days of the Saint Paul Medical School. His refusal to dispense liquor following national prohibition was an indication of his probity and adherence to his convictions.

Dr. John Frederick Russ
1866-1930

Dr. John Frederick Russ of Blue Earth, Minnesota, died at his home August 13, 1930, of cancer of the stomach. Dr. Russ was born in Buffalo, New York, in 1866. His medical training was received at the University of Iowa, where he received his degree in 1893.

Dr. Alfred Erwin Comstock
1872-1930

Dr. A. E. Comstock, Saint Paul, died a few hours following a stroke July 24, 1930, at his home. He was born at Fayette, Iowa, February 21, 1872, and was the eldest of six.

In 1895 Dr. Comstock obtained the degree of B.S. from the Upper Iowa University and M.D. from the Hahnemann Medical College of Chicago in 1899. He came to Saint Paul in 1900, and was associated for a year and a half with the late Dr. W. S. Briggs. His practice of late had been limited to surgery.

For some ten years Dr. Comstock was professor of surgery in the homeopathic department of the University of Minnesota, and for the past twenty-one years was chief surgeon for the Beneficial Association of the Omaha Railroad. He was a member of the staffs of St. Joseph's and St. Luke's Hospitals and for more than twenty years was visiting surgeon at the Ancker Hospital. At different times he had the benefit of postgraduate study at Vienna, Paris, London and Berlin.

Dr. Comstock was commissioned captain in the Medical Corps at the time of the World War and spent six months overseas attached to Mobile Hospital No. 103. From April, 1926, to February, 1929, he was executive secretary of the Minnesota State Board of Medical Examiners and at the time of his death was a member of the University, Minnesota, and Town and Country Clubs. He was also a Royal Arch Mason.

On February 8, 1907, Dr. Comstock married Miss Minnesota Berkey of Saint Paul, who survives him with a daughter, Minnesota, and a son, Alfred Erwin, Jr.

TESTICULAR GRAFTING

At the International Physiological Congress in Boston last summer, Voronoff boldly reported in relation to his widely proclaimed testicular grafting that the successive phenomenal results of the transplantation are now definitely established. Recently, Moore has discussed the astounding claims that are prevalent in this field and remarks that the absence of dependable indexes for the alleged "hypogonadism" in man, or the inability to utilize proved indicators for hormone introduction by any means, appears to have caused but little concern to clinicians employing these supposedly remedial measures. Astonishing as it may be, published statements of the effect of hormone introduction, or alleged hormone increases from the intact organs, claim improvements for conditions that fairly well exhaust the ills to which man has fallen heir. Moore concludes that there is no known acceptable evidence that non-viable testes grafts, that is, grafts that fail to become incorporated with the body and actively secrete, exert any immediate or remote beneficial effect on the host organism. (Jour. A. M. A., July 19, 1930, p. 203.)

PROCEEDINGS OF THE MINNESOTA ACADEMY OF MEDICINE

Meeting of May 17, 1930

On Wednesday evening, May 17, 1930, at the Minnesota Club, St. Paul, the Minnesota Academy of Medicine, in lieu of its regular May meeting, gave a Founders' Dinner in honor of the living members of the group that founded the Academy in 1887. There were 75 members and guests present.

Dr. Emil S. Geist, President of the Academy, acted as toastmaster.

Dr. Geist: Members of the Academy: In honoring our guests this evening we but honor ourselves. Of the forty founders of this association, ten are living today. They are

Dr. Frank Allport
Dr. R. O. Beard
Dr. J. W. Bell
Dr. H. M. Bracken
Dr. William Davis
Dr. F. A. Dunsmoor
Dr. J. F. Fulton
Dr. W. A. Jones
Dr. Justus Ohage
Dr. Thomas S. Roberts

We regret that Drs. Allport, Bracken and Dunsmoor are not with us this evening.

You will note that the majority of these gentlemen hail originally from Minneapolis, which may be proof that perhaps after all Minneapolis is a more salubrious city than St. Paul.

1887! That was the year of the founding of this Academy. At that time St. Paul had about 115,000 inhabitants and Minneapolis perhaps a few more. That was the time of the great "census war" when there existed much rivalry between the sister cities. Even the inhabitants of cemeteries were counted as "population" and no doubt our honored guests did their level best at that time to increase the population.

That was the time of the horse, the gas lamp, the horse-car and the cable-car.

St. Paul was a much smaller city than it is today. The Cathedral stood on the site occupied by the Hamm Building, filled as it now is with doctors. Can this be termed progress?

The end of Summit Avenue was at Dale Street. Beyond that was wilderness. Third Street was the chief business thoroughfare. Who of us does not remember the Tivoli and the Merchants Hotel? Who does not recall the old Windsor Hotel, located as it was across the street from the building occupied by a large group of physicians? And its bar?!!

To get to Minneapolis was a hardship. One availed oneself either of the railroad or took a horse and buggy. In either event it was a day's journey. Minneapolis had emerged from being St. Anthony Falls. Washington Avenue was "the" business street. It was the day of the Exposition Building and the "Panorama." The University was still a baby. There were not only large flour mills but also large lumber mills, the latter now a thing of the past.

In those days golf was unheard of. For amusement the doctors went fishing, boating and hunting. The Mississippi River, our finest asset, was much used for these purposes. It had not yet become a glorified sewer.

In introducing the first speaker, I am introducing the man whose mind conceived this organization. He was also its *first* President. He is with us tonight, as young as he ever was.

I take great pleasure in introducing Dr. John F. Fulton of St. Paul. (Applause.)

Dr. Fulton: In October, 1887, a few representative medical practitioners of the Twin Cities assembled in the West Hotel, Minneapolis, for the purpose of organizing a medical society with the intention of bringing together all of the specialties in medicine and thus combine the most powerful aids for the advancement of general medicine and surgery, keenly appreciating the fact that the specialist whose education is not well-founded on the art and science of general medicine is not worthy of recognition by the profession, and believing that the specialist, from the enthusiasm in his profession, devotes his entire life to the double object of planting seeds gathered from the great stores of general medicine into his special soil in order to return gratefully to general medicine the harvest which is ripened fruit. A specialist can make no advance or discovery in his field which will not have a beneficial effect upon all branches of medicine. So it was the wish of those who organized this Academy, expressed in the language of another, that each specialty should be a diamond held together by a string of gold which is scientific medicine and surgery.

Ophthalmology was the first specialty to establish itself as such. But no class of men have been so constant and determined in retaining their coöperative relationship with other branches of medicine. As an illustration, Doctor Cushing, in a recent address, referring to the maladies of the optic chiasm, remarked that this was the crossroads where the ophthalmologist, the physiologist, the pathologist, the neurologist and the general surgeon met, but the ophthalmologist holds the right of way. The association of the oculist and the neurologist has always been most intimate.

In 1865 Sir Hughlings Jackson said, "It is imperative in all cases of cerebral disease to examine the eyes with the ophthalmoscope whether the patient complains of defect of sight or not. The intraocular condition most frequently discovered is double optic neuritis and it is very common for this to exist in a patient who can read the smallest type and who supposes his sight is good."

In a recent address, Dr. Edward Jackson declared: "It is a modest inference going little, if any, beyond what individuals have already received, who claim that ophthalmoscopic examination of the optic nerve will, in the very near future, play as important a part in the observation of general disease as the feeling of the pulse did seventy years ago."

This is a very strong indication of the progress that

has been made in the development of the ophthalmoscope as a diagnostic instrument in general practice from the days of Sir Hughlings Jackson, of England, to the present day of Dr. Edward Jackson of America.

No one gave a greater impulse to the value of the ophthalmoscope in diagnosis than Sir Clifford Allbutt. His epoch-making monograph on the use of the ophthalmoscope in diagnosing diseases of the brain and spinal cord and of optic neuritis in pyemia is one of our most useful textbooks today.

The importance of medical opthalmology was quickly recognized by American physicians, among the first being S. Weir Mitchell. I know that every member of the Academy is familiar with his magnificent work along this line. It was this genius of our profession who first used the word "eyestrain" in his classification of headaches.

Other American authorities, such as William F. Norris, of Philadelphia, during my student days, insisted that all patients in the University Hospital of Pennsylvania should have careful ophthalmoscopic examinations.

The relation of the eye to the central nervous system has been referred to as the "bulletin board of diseases of the brain and the spinal cord." Of the twelve cerebral nerves, six are distributed partly or wholly in the eye and its appendages.

Now that so many of us are in a historical turn of mind, I am reminded that I was in Berlin when Koch first announced his tuberculin treatment of tuberculosis before it had been thoroughly investigated. It was claimed at the time, as I remember, that he was forced to do this by the high government officials on account of the international medical convention which was in session in Berlin at that time.

Mr. Treachor Collins, of London, was one of the first to test tuberculin therapeutically for ocular tuberculosis. The pathology being situated as nodules on the edge of the pupil, the result was disastrous, starting up a severe reaction which resulted in the loss of the eye. This did not discourage Mr. Collins, however, from continuing the use of tuberculin therapeutically for ocular tuberculosis, as he has recently pronounced it a most reliable and satisfactory remedy for this condition.

It is to be hoped that this Academy will use its influence to establish a great library in this community, such as the one that has recently been opened in the East, and others that are about to be opened, in which will be stored all of the treasures of medical literature. In the language of one who is the maker of books himself and a lover of books and literature, "It should not be a graveyard for the accumulation of volumes only to be forgotten, but in which there is a spirit world of books, useful to all who know how to use them."

The doctor need not go outside of his own profession in order to find absorbingly interesting literature. The chapter in Ballory-Radot's Biography of Pasteur on the working out of a vaccine for the relief of hydrophobia is the most thrilling and interesting that can be found in any literary production. And Cushing's Life of Osler is one of the most popular books that has been written in many years. If there is any member of this Academy who has not read it, he has a great treat ahead of him.

Since this Academy has been organized ophthalmia neonatorum has been eliminated; sympathetic ophthalmia is a rarity, and trachoma is confined to localities where hygienic conditions are not obtainable.

But what of the future? What will we have to report forty years from now? We are expecting much. Our hope, however, hangs on physiology, biochemistry and biophysics. The two conditions that will be most improved by such progressive development in opthalmology will be glaucoma and lenticular and corneal opacities. In regard to the latter, Duke Elder in a recent address expresses himself as follows: "Cataract, as we have seen, is another purely physico-chemical problem, the denaturation, hydrolysis and coagulation of the proteins of the lens—and the essential opacities which occur in the cornea seem to be of the same nature. All of these conditions will before long be explicable, and all of them should eventually be curable or preventable by physico-chemical means"; all of which I endorse.

With a more thorough knowledge of the internal fluid circulations of the eye and the study of the function of the supplementary system of circulation, known as the lymphatics, we have every reason to hope that the syndrome known as glaucoma will become preventable and then, when it does occur, its course will be checked from the disastrous course which we now think is inevitable.

I am enthusiastic in the belief that this Academy will continue to be a careful recorder of clinical observations, the encourager of laboratory investigation, and a just endorser of new, meritorious therapeutic agents.

I cannot do better in closing than to repeat a quotation from Sir T. Brown, as I did in my first address to this Academy, "Where Nature fills the sails, the vessel goes smoothly on, and where judgment is the pilot, the rate of insurance need not be high. Where industry builds up Nature, we may expect pyramids, but where this foundation is wanting, the structure must be low. They do most by books, who could do much without them, and he that chiefly owes himself unto himself, is a substantial man." (Applause.)

Dr. Geist (introducing Dr. Bell): In 1887 Lake Harriet was far away from Minneapolis. It was used for picnic purposes. Today it is surrounded by dignified city homes. It was my privilege to invite the next speaker at one of these homes. Dr. Bell has seen Minneapolis grow from infancy to mature manhood. During that time everything about Minneapolis has changed excepting himself, who has remained ever youthful. I take great pleasure in introducing Dr. John W. Bell, of Minneapolis. (Applause.)

Dr. Bell: On an occasion of this kind we naturally focus our attention upon the past. As early as 1885 the progressive physicians of the Twin Cities felt that

the time had arrived for the founding of a State Society that would especially appeal to those interested in original work.

Fortunately the founders of the Minnesota Academy of Medicine were not confronted by the unfortunate situation existing today of innumerable and overlapping medical societies and organizations, tending to weaken rather than strenghen the county, state and national groups. Personally, I feel that Drs. Fulton, Abbott, Wells and Beard are largely responsible for the birth of this organization.

Our first Secretary, Dr. R. O. Beard, who continued to labor for fifteen years in the interest of the Academy, undoubtedly had much to do with shaping its policy and destiny. It gives me great pleasure, after the many years of useful and unselfish service he has given to the Academy and to Medicine in general, to have him still active in Public Health work.

The Minnesota Academy of Medicine has had, and will doubtless continue to have a prominent part in shaping the course and destiny of things medical in the State and Northwest. (Applause.)

Dr. Geist (introducing Dr. Ohage): The next speaker your all know. I think perhaps you know him better than I do; I am still trying to figure him out. I take great pleasure in introducing Dr. Justus Ohage, of St. Paul. (Applause.)

Dr. Justus Ohage: Gentlemen: Being one of the charter members, and perhaps the oldest, of this organization, the present President, Dr. Emil Geist, of Minneapolis, requested me to make a few remarks about surgery at the present time compared to that half a century ago. A few years ago I had the pleasure of visiting one of the largest and finest clinics in the country, the Mayo Clinic at Rochester, Minnesota. Its grandeur, thoroughness and success were a marvel to me and I could not help comparing the facilities and resources of this institution to conditions which I had to face 50 years ago. Then there were but few hospitals, most operations were done in private houses under very bad aseptic conditions, different assistants, few nurses and often after hard and strenuous trips. My main reliance, and it is still the best, against sepsis, was scrupulous cleanliness with bichloride as an adjuvant. Often I had to be my own assistant, caretaker of instruments and dressings, while the local surgeon administered the anesthetic.

I will recite you only a few cases out of very many. In the winter of 1883, Dr. E. Y. Chilton, of Howard Lake, Minnesota, called me for an operation for intestinal intussusception. The doctor met me with his cutter at the depot and after an eight-mile ride over rough roads and snowbanks at 35° below zero, we arrived at the farmhouse where the patient lived. I operated, Dr. Chilton gave the ether, and an old farmer with a huge beard held the kerosene lamp for light. He got his whiskers over the lamp chimney, which set his beard afire. He fell and fainted, the lamp exploded and set the kitchen where we operated on fire. I had just relieved the obstruction and was ready to close the abdominal wound. I lugged the patient into the cold adjoining room, the fire was extinguished and I closed the abdomen, dressed him and put him to bed He made a clean recovery.

A year later I did an ovariotomy for Dr. Wm. Lincoln at Wabasha, Minnesota. The patient was the wife of the railroad section foreman. The operation was done in the sitting room of the section house. Dr. Lincoln assisted and a druggist gave the anesthetic. The operation was an easy one and after removing the tumor, Dr. Lincoln sponged out the abdomen while I was getting the sutures ready. At that period I used sea sponges previously boiled. Upon inquiry he answered me that everything was out. I closed the abdomen, applied the dressing and had the patient put to bed. I had heard of things being left in an abdomen and their dire consequences and always counted every instrument and sponge before and after an operation. Everything was accounted for but instead of six, I could find only five sponges—one was missing. We hunted all over the room, under tables and in closets, in the yard where the bloody water was thrown—but no sign of the sponge. I concluded if it was anywhere it must have been overlooked and still be in the abdomen. By this time her husband had joined in the hunt and he became rather boisterous and not very complimentary in his vocabulary. The situation was not a pleasant one. A wild, powerful Irishman, his wife just recovering from the anesthetic and a sponge in her abdomen! A last I succeeded in getting the patient back on the table, reopened the wound and found the sponge behind a coil of intestines. The patient made an uneventful recovery.

In the year 1886 I operated in St. Joseph's Hospital two cases for gallstone trouble: the first was a cholecystotomy and the other a cholecystectomy. Both cases recovered and lived to a good old age. They were the first cases ever operated in America. I published them in the "Medical News" of Philadelphia, Feb. 19 and 26, 1887, then the leading medical journal in the United States. I incidentally mention this as Dr. Geist claims the honor of priority for a member of the Minnesota Academy of Medicine. The feasibility and success of these operations having been established, they are now frequently done and have saved many lives and allayed suffering.

When the new and modern St. Luke's Hospital on Smith Avenue was dedicated, I was selected to do the inaugural operations: a resection of the stomach for malignant disease, and another patient for gallbladder trouble.

I operated before the senior class of the State University. Among the students were four young women. I was always skeptical about women entering the medical profession and at this occasion thought their attention was rather poor. I looked for a little revenge. During the gallbladder operation, I saved a little of the bile in a tumbler and with my talk about the operation I drew attention to the necessity of close observation. The *vox viva* of the teacher and an occasional addition of a little "Attic salt" will make a lasting impression. "Some of you," I told them, "may

settle in a small country town and get into a talk with some of the old wise women of the place. They will watch and judge you. They may ask your opinion about poor Mrs. Brown vomiting yellow bile and bitter as gall. So you may know everything about bile, I pass this sample. You can tell its weight, see its color. smell its odor, and if you do as I do, put the tip of your finger in it and taste it, you can tell whether it is bitter or not. Now have you all examined it?" "Yes." "Is it bitter?" "Very." "Then you all are poor observers. You did not observe that I put my middle finger into the bile and my index finger in my mouth."

The Minnesota Academy of Medicine has well done its share in advancing the progress of medical sciences and will certainly continue to do so.

Vivat—Crescat—Floreat! (Applause.)

Dr. Geist (introducing Dr. Roberts): In 1887 the next speaker was a young man. He is still a young man. He was then an excellent physician and ornithologist. He is still the same. During the past years he has devoted more of his time to his glorious hobby —"birds"—and his work for, about and among them is known all over the country. Long may he live! I take great pleasure in introducing Dr. Thomas S. Roberts, of Minneapolis. (Applause.)

Dr. Roberts: I wish to take this opportunity of thanking the committee that arranged this dinner. I was not aware until notified by our President and Secretary that I am entitled to a place among the Founders of the Academy. Such being the case, the honor must have come through the courtesy of my friend and preceptor, Dr. A. W. Abbott. I had the good fortune to be in his office for two summers before, and to be his surgical assistant for nearly seven year after my graduation. A more kindly, unselfish and loyal friend no young man ever had.

Dr. Ohage has told you of the primitive conditions under which surgery was often done in those pre-hospital days. The operating room was not infrequently the kitchen or living room of the patient's home and the operating table was usually the kitchen or laundry table. The helpers were members of the family or interested and curious neighbors; trained nurses were few and far between; the kitchen kettles and pans and stove provided the means for such sterilizing as was done; and not many of the things considered so essential today were at hand. However, the results were surprisingly good considering the increased risks incurred from the present point of view. Some years ago Dr. Abbott read before this academy a paper presenting in his happy manner a picture of those good old primitive pioneer days.

Having mentioned Dr. Abbott as a physician and surgeon, I may perhaps be permitted to present him in another aspect, unknown I imagine to most of you who knew him well in and out of the Academy. When I first became acquainted with the Doctor, I was acting as Secretary of the Minnesota Academy of Natural Sciences. Many of the original members of that organization were physicians, as it was the era when medical men quite generally were interested in the natural sciences. As a boy I turned naturally to such pursuits, attended the meetings of the Academy and became a member while still a student in the Minneapolis schools. A little later Dr. Abbott was admitted to membership and it is of his hobby or special interest that I wish to speak. He believed, whether independently or not I cannot say, that it might be possible to determine the age of a fish by studying the concentric lines of growth on the scales. He collected considerable material and made a beautiful series of enlarged fish scales of various species. The Smithsonian Institution and the United States Department of Fisheries with Dr. Spencer F. Baird in charge became interested in the Doctor's work and a correspondence developed. Dr. Abbott was preparing a paper embodying his findings which was to be illustrated with his drawings, but, becoming more and more occupied with a rapidly growing practice, he gradually drifted away from his project and failed to establish the truth of his thesis. Now, curiously enough, this is the recognized means of determining the ages of fishes. Had not Dr. Abbott become so absorbed at that time in the practice of his profession, it seems certain that he would have carried his studies far enough to have become a recognized pioneer in this scientific, but practically important, line of research. Dr. Abbott had a scientific, inquiring type of mind but he allowed his profession to stifle all outside interests. Today whenever I chance to open a work on ichthyology and see the illustrations of fish scales, depicting the regular series of striæ, my mind goes back to the beautiful collection of drawings that Dr. Abbott made so many years ago.

In closing, I wish to add my appreciation of the honor paid by you tonight to the small group of Academy Founders gathered around this table. (Applause.)

Dr. Geist (introducing Dr. Davis): In 1887 I was a nine-year old boy living in St. Paul. Our home was situated on the street running between St. Luke's Hospital and St. Joseph's Hospital. I recall seeting Drs. Wheaton, Stone, Fulton, Gillette, Ohage and others passing by in their buggies, vying with each other as to who had the "classiest" rig. Of these, I think Dr. William Davis' outfit attracted my attention more than the others; possibly because he had the best horse. I take great pleasure in introducing Dr. William Davis, of St. Paul. (Applause.)

Dr. Davis: Mr. President, Members and Guests of the Academy. An old camp-meeting preacher introduced his sermon with the modest statement that he would now proceed "to limit the illimitable, to fathom the unfathomable and unscrew the inscrutable." The inscrutable which I propose to unscrew is the beginning of the Academy. Previous speakers have given you their version. I will tell you now just how it was begun.

In October, 1887, the late Dr. Perry H. Millard came to the office which I shared with Dr. Witherle and told us of a plan to found an Academy of Medicine, made up of twenty men from St. Paul and twenty from Minneapolis, to hold monthly meetings alternately in the two cities. Dr. Millard was a great getter-up of things. It was largely through his instrumentality

that our State Medical Practice Act was brought about, and Minnesota was one of the first states to pass such a law. Then, too, he was foremost in establishing a teaching faculty at the Medical Department of the State University. There had been a medical faculty but it had been a paper faculty only. Dr. Millard accomplished the difficult task of getting the faculties of the St. Paul Medical School and of the Minneapolis Hospital Medical College to come to such an agreement as to unite and form the present Medical School of the University of which we all are so justly proud. When he told Dr. Witherle and me about the proposed Academy and said, "and you two gentlemen are invited to join," I was very glad to accept, for at that time the local medical societies were at a very low ebb. The profession in Minneapolis were divided into two hostile camps that fought one another tooth and nail. Many of the good men would not belong to the Hennepin County Society and had formed a new one, the Minneapolis Society of Physicians and Surgeons. Indeed, the antagonism was so bitter that a Minneapolis doctor whom I had known in the East told me seriously that he believed some of the men in the other camp had tried to instigate a malpractice suit against him. In Ramsey County we were more harmonious, but there was no enthusiasm for the Ramsey County Medical Society, which met around in doctors' offices, often cheerless and dimly lighted rooms, usually with no program prepared and with the scantiest attendance. Indeed, of one meeting the secretary, Dr. Spencer, made the report that those present were the president and secretary and his, Dr. Spencer's, dog Peter, and he drew a picture of Peter on the minutes, a picture which is on the records today.

From the start the Academy was a success, although it suffered from several handicaps. For one thing, the only transportation between the cities was by the steam railroads which ran half-hourly trains up to nine o'clock at night and less frequent trains after that. Then, too, there was sure to be a preponderance of the members from the city where the meeting was held. But when, three years later, through cars began to run on the street railway between the two cities, and when the meeting place was changed to the Town and Country Club, and best of all when the automobile came along and made access to the meetings quick and easy for us all, the attendance grew to such a point that at the April meeting the secretary reported that over fifty members had been present at the March meeting, and I am sure there were fully as many in April, while as for the enthusiasm, that leaves nothing to be desired.

There is an excellent story I read once called "The New Minister's Great Opportunity," which tells how a young minister, called to a country parish, found that almost the first duty expected of him was to conduct the funeral obsequies of the village patriarch, old Uncle Capen, who had just died over one hundred years old. And everyone said what a wonderful chance this was for the new minister to tell about Uncle Capen's remarkably long life. But when the minister came to look about for material for the expected eulogy he found very little to help him, for Uncle Capen had led a most colorless life. His occupations had been chiefly sawing wood and whitewashing, and he had much preferred to sit by the kitchen stove to doing either of these. He had taken no active part in social, civic, or political life. So when it came to the funeral, the minister spoke of the great age of the departed and then proceeded to tell of the great changes that had come during his lifetime. He described the invention of railway trains and steamboats, of the telegraph, of photography, and other inventions, and his hearers were delighted with the address. But afterwards one of the parishioners said to the minister, "I enjoyed your remarks at the funeral but there did not seem to be much about Uncle Capen in them." "No," said the minister, "but you must admit that I did not say anything that was not so."

Now I propose to borrow a leaf from the minister and instead of talking about the first members of the Academy and perhaps saying things that were not so, to look back at the changes that have taken place in medicine during the forty-three years of the Academy's lifetime. First of all I think it will be interesting to see what diseases headed the death list in 1887. Some of you will not be prepared to hear that the chief cause of death was cholera infantum, a disease that has disappeared entirely from medical nomenclature. And when we add the deaths from the related diseases, colitis, enteritis, enterocolitis, and gastroduodenitis, with moreover the large number of deaths ascribed to convulsions which were really the end result of diseases of the same class, the total is over four hundred, more than twice that of the number of deaths from the next on the list,—pneumonia. Cholera infantum and these allied diseases are all grouped together today under the title of the diarrheal diseases of infancy, the total deaths from which in St. Paul last year were sixteen. I am giving you the figures of St. Paul. Those of Minneapolis would be little different except that there was more typhoid there at that time because the city drank untreated river water.

The second cause of death, pneumonia, holds high rank today, being third in last year's list; but the third, typhoid fever, accounted for but four deaths last year. Tuberculosis of the lungs, then listed as phthisis, was fourth, and that has dropped now to sixth place. The next, diphtheria, caused only five deaths in 1928. Our list today is headed by heart disease, which was then eighth, causing fewer deaths than infantile convulsions. Next to heart disease, cancer now prevails. In 1887 cancer held sixteenth place. Certainly medical science has much to be proud of in that it has practically abolished three diseases that were prime causes of death at the time of the birth of this Academy.

The hospitals of 43 years ago were small and few in number, often merely dwelling houses made over for hospital purposes. Except during the typhoid season they had few medical cases and very few confinements. Today about four-fifths of the births take place in hospitals. Except for the insane there were no special hospitals like those for tuberculosis and for crippled

children today. Even the hospital for the insane was more often called an asylum than a hospital. There were no specially fitted operating rooms with their white enameled furniture, their sterilizing rooms, gloves, caps, and masks. If gowns were worn they were chiefly to protect the surgeon. Anesthesia was with chloroform or ether as the surgeon chose, and the choice between the two was about equal. Cocaine had just appeared but was used chiefly in eye operations. Local anesthesia came much later. The present-day clinics had not come into being. Will Mayo had been in practice but four years and Charlie Mayo had not even taken his degree, and the great clinic whose buildings rise like landmarks from the prairies of southern Minnesota had not even been dreamed of.

That was the era of antiseptics. Carbolic acid was going into the discard and bichloride was taking its place. For hand disinfection this was used in the strength of 1-1,000, for irrigation from 1-2,000 to 1-4,000, while instruments were sometimes put into solutions as weak as 1-15,000, which could have had little germicidal power. Asepsis and sterilization by heat came several years later. This was curious, because in 1886 Lawson Tait, of Birmingham, had published a series of 139 consecutive abdominal sections without a death. These statistics never were questioned, as in each case reported he gave the initials of the patient's name and the name of the physician by whom the case was referred. At this time Lister and Spencer Wells were satisfied with 85 to 90 per cent of recoveries. Lawson Tait scorned chemical antiseptics but he was scrupulously clean. He used water from the tap to wash out the abdomen and said he sometimes put a little carbolic acid into the bag of sponges to keep out the flies. The sponges, by the way, were real sea sponges, washed as clean as possible after each operation and used again. Yet no one learned from Tait that cleanliness, including boiling water, was the real thing.

It was only a year before the date of the Academy's birth that Fitz, of Boston, gave to the world the word appendicitis, and showed that what was then called typhlitis, perityphlitis, or often only inflammation of the bowels, was really a diseased appendix. Even in 1887 operation was rarely done except in the presence of a tumor or for manifest peritonitis. What a boon that word appendicitis has been to the profession! Who can measure the value in dollars and cents?

Ulcer of the stomach, now so common, was diagnosticated but seldom in those days. The books spoke of it as uncommon and discouraged its diagnosis unless hemorrhages were present. Ulcer of the duodenum was rarer still. Of course there was no *x*-ray, and other instruments of precision like the sphygmomanometer and the electrocardiograph had not been invented. Infantile paralysis in epidemic form was not known, nor was it regarded as communicable. Until 1889 there had been no epidemic of influenza for forty years and no one had seen it until it appeared that winter.

In obstetrics there have been great changes. In proportion to the number of births there were in 1887 ten times as many deaths from puerperal sepsis as there were in 1928. Most remarkable is the frequency of cesarean section today. In St. Paul the first successful operation of this kind was not done until 1889. Today cesarean section is done for slight degrees of dystocia, for placenta previa, for concealed hemorrhage, for eclampsia, for almost no reason at all or because mothers think it easier than normal childbirth. Indeed it is getting so popular to have babies come into the world by the front door that the lying-in wards of our hospitals may be obliged to put out the notice often seen at the entrance of apartment houses, "All deliveries must be made at the rear."

Of the cults and systems of medicine, homeopathy was active in 1887 and we were still mistakenly fighting it. Now that we consult with him and welcome him to our societies, the homeopath is becoming a rare bird. Osteopathy then was in its infancy, but as he grows up the osteopath is getting educated and no doubt will eventually become merged with us, like the homeopath. Christian Science was already active, but that is only our old acquaintance—faith cure—dressed up in the ungrammatical platitudes of Mrs. Eddy. Of quacks we have had John Till in Wisconsin plaster the backs of thousands and gather enough dollar bills to plaster his house inside and out. In California we have seen Abrams become a millionaire with his electronic device. Another quack whose name escapes me, but who reaped a great harvest by pretending to make a diagnosis by examining a drop of the blood, reminds me of a story told here some thirty years ago by our dear old friend, Dr. A. W. Abbott, about a quack named Dr. Jack who made his diagnosis by examining a specimen of urine. On one occasion a man brought him a bottle of urine to examine. The quack looked at it and said, "This is your wife's urine." "Right," said the man, "What is the matter with her?" The quack pondered a moment and then said, "She has fallen down stairs." "That's right," said the man, "how many steps were there?" "Nine," said the quack after a moment's hesitation. "You're wrong," said the man, "there were twelve steps." The quack looked at the bottle again. "Did you bring me all the urine your wife passed?" "No," said the man, "I couldn't get it all into the bottle and had to leave some behind." "Well," said the quack, "those other three steps were in the rest of that urine."

Cults may rise and disappear, quacks may flourish for their short day, but the science of medicine goes on like a mighty wave, not crushing all that lies in the path like the steam roller of the politicians, but lifting up and absorbing to itself all that it meets that is good. To this progress the Academy has contributed its full share during the forty-three years of its existence. I am proud to have been one of its founders, and I predict for it a long-continued career of usefulness by contributing to the enjoyment and professional advancement of the medical men of this part of the Northwest. (Applause.)

Dr. Geist (introducing Dr. W. A. Jones): The next speaker whom I am about to introduce needs no

introduction. We all know him and love him. We have just heard Dr. William Davis, who was the first editor of the Journal-Lancet. It is fitting for us to hear from the present editor of that publication. I take great pleasure in introducing Dr. W. A. Jones, of Minneapolis. (Applause.)

Dr. Jones: I hardly know where to start in an attempt to talk, but I am very much impressed with Doctor Davis' talk on the diseases of those days and the fact that he did not mention marasmus. No one knew what it was. A non-medical man started an investigation to find out what it was. Since then it has disappeared entirely.

I recall a great many incidents in my brief career which were very interesting. I remember once I was consulted by a medical man who had a lady patient with him. He said he had studied the case very carefully and thought it was a case of inflammation of the prostate gland!

I want to tell the Academy that I am one of the proud members of this organization but I did not remember that I was one of the founders of it. I am very glad to be a member, and have watched its progress and enlargement since 1887. It doesn't seem possible that a man could get along with so many medical men so amicably. I want to extend my thanks to them and I hope they will always be successful as physicians and hope they will keep up their membership not only in this organization but in the State society and the American Medical Association. (Applause.)

Dr. Geist (introducing Dr. R. O. Beard): The next speaker is also known to most of us. There are few of us in this room who did not receive instruction from him—instruction the value of which we still appreciate. The chief memory I have of his lectures is that of a continuous flow of oratory. He, too, seems to have found what Ponce de Leon searched for in vain. I take great pleasure in introducing Dr. R. O. Beard, of Minneapolis. (Applause.)

Dr. Beard: Mr. President and friends of the Minnesota Academy of Medicine: As one of the founders of the Minnesota Academy of Medicine, I want to assure its members of our deep appreciation of the honor you have paid to us all—and alike to those of us who are living and to the lasting memory of those who have been lost to us during the forty-three years of the life of this remarkable body.

There were forty charter members of the Academy. It gives us pause and it quickens the embers of still warm remembrances in our minds to recall the fact that thirty of these forty men have already gone "to that bourne whence no traveler returns."

It is something for which we will be glad and grateful to the end that we have had the privilege of association and the joy of friendship with these whom we knew so long, whom we loved so well, and have so early lost. It is much to have worked, hand in hand and shoulder to shoulder, with men so rare as Abbott, MacLaren, Wheaton, Stone, French, Ritchie, Senkler, Clark Stewart, Nippert, Dunn and the many others who answered to our monthly muster-roll.

It is a happiness to know that these men, each in his own measure, were permitted to "snatch their narrow portion of time out of eternity"; that they were fitted "to do the work of men while they bore the form of them"; that they contributed greatly to the growth of the profession they loved, rendered their large service to mankind, lent something to the literature of medicine and to the literature, at large, of human thought.

We reverently salute the memories of these gone, but unforgotten friends!

The dawn of history is ever shrouded in more or less of mystery, and men have had to rely, more or less, upon tradition and recollection for the initial setting of any event. It is inevitable that in this half-light of other days the details we recall may, in some degree, differ. Great minds, it is said, move at a given time in one and the same direction.

I have been asked to give you some reminiscences of the Academy's past; and at risk that reminiscence is the somewhat faded fruit of the decadent years, I must needs comply with the request.

I remember then, a certain meeting of the Minnesota State Medical Society at Duluth in the spring of 1887. I recall the fact that, on the return trip, French, Hunter and I sat together, and that on the way French initiated a proposal to establish a select association of medical men and that the three of us discussed the possibility. I remember that, within a few days of our return, the same three met in Hunter's office and talked it over again. Then and there it was proposed that the Academy be limited in number and that its active membership should be drawn equally from the Twin Cities. I recall that we proposed three Saint Paul conferees, and that these three were Fulton, Wheaton and Stone; that French undertook to suggest the matter to these three brethren. Later, the six of us had a meeting which extended from Alex Stone's office to the Windsor Hotel in search of refreshments, and that other men were proposed by each and all of us. Among them were Ritchie, Riggs, and dear old Senkler, of Saint Paul, and Abbott, Allport and Dunsmoor, of Minneapolis.

On October 7, as the records show—and here actual history begins—an organizing meeting was held in Saint Paul, at which nine Minneapolis men and seven Saint Paul men were present. On October 12, a second meeting completed the organization.

It is a personal pleasure to the speaker to recall that he was privileged to write the Constitution, By-Laws and Standing Rules then adopted. The minutes of succeeding years show that while these documents were revised from time to time, they remain today the structural basis upon which the Academy was built and upon which it has rested ever since.

On November 5, 1887, the first regular meeting of the Academy was held, at which the first officers of the Academy were chosen. They included Dr. John F. Fulton, as President; Dr. A. W. Abbott, as Vice-President; Dr. LeGrand N. Denslow, as Treasurer;

while Dr. Edward C. Spencer and the speaker were jointly named as Secretaries.

For a year these two Secretaries collaborated, and the satisfaction of working with so essentially a Nature's gentleman as Edward Spencer is to be recorded. At the end of the first year, Dr. Spencer was assigned to the Treasurership and the speaker became the sole Secretary. In still another year, he was elected Secretary-Treasurer, a joint office which he filled for fifteen years. He may, perhaps, be permitted to boast of the possession of the unshared honor and the privilege of having served, in turn, as Secretary, Secretary-Treasurer, Vice-President, President, Fellow, and the Honorary Fellow, as, by your courtesy, he now ranks.

The pivotal point upon which the speaker believes the wonderful success and stability of the Academy to have turned is to be found in the stated purposes of its creation, viz., the cultivation of medical research and the association of medical men upon a basis of good fellowship, professional ability and literary merit. So strictly has entrance to the Academy been guarded by this statement of its objectives that the initial quality of its membership has been in its entirety continuously maintained. It has always been esteemed an honor to belong to the Minnesota Academy of Medicine.

In a time of professional differences and disintegration, the Academy has embodied a satisfying harmony. In the face of a progressive diminution of educational standards in the State, it has stood for lofty ideals. In the midst of current commercialism, on the one hand, and ethical fundamentalism, on the other, it has remained stanch to the highest traditions, translated into the modern spirit of medicine. In a day when pseudo-scientific research has easily passed muster, it has exercised real discrimination of medical values.

May I be permitted a word of greeting to my fellow-founders, all so warmly welcomed to this table.

I am glad that we still belong to The Minnesota Academy of Medicine. Although we need not now bear the burden and heat of its developmental years, in which we carried our fully-accepted share, we may continue to take our part in the councils which are functional to age and to grow young in the fellowship of its sustained youth.

We have lived in a past when Art has added much to Science and Science has carried Art aloft upon its lifting wings. We have lived in a present marked by vast material and mechanical progress and by still greater illumination of the human mind. We look out upon a future which promises the prevention of the human ills we have wrestled with, the advancing betterment of human being, the increasing longevity of humankind.

It is ours to hold an enlarging and enlivening memory of the days bone by; to grow still more greatly under the constantly expanding influence of these contemporaneous years; to vision with widening philosophy, with still gathering wisdom, with deepening understanding, the coming days.

It is not permitted to us to halt, for if we do the rapidly rising waves of this living present will pass us by. It is ours still to keep step with the constantly compelling movement of our times.

Like the native music of America, our lives are set to a minor key, and for the identical reason that gives us this native chord. The old age of the individual is like the old age of the race. Its face is turned toward the setting sun. But that minor key is the most beautiful in the entire gamut of musical sound. We may beautifully keep in tune with it.

We have reached the years when we may stand, if we will, by the lift of our past experiences, upon "those summits whence the eye sees the world as one vast plain and one boundless reach of sky."

In sweetness, quietude and seriousness, it remains to us "so to live, that when the summons comes to join the innumerable caravan that moves to that mysterious realm where each must take his chamber in the silent halls of death, we go not like the quarry slave at night, scourged to his dungeon, but sustained and soothed by an unfaltering trust, approach our end as one who draws the draperies of his couch about him and lies down to pleasant dreams." (Applause.)

Dr. Geist: Eternal Youth! Dr. Beard, you have made all of us feel young again. As I listened I was recalled thirty years back to that old physiology lecture room and its hard, hard benches; those straight-back affairs!

I now bring this meeting to a close. It has been fine to have had with us our beloved Founders. We regret much that some of them were not able to be with us.

Founders! May you live long and may we enjoy your presence for many years to come. All Hail to You!

Dr. Thomas Roberts then showed two reels of moving pictures of Minnesota's wild animal and bird life.

R. T. LaVake, M.D., *Secretary.*

POMPEIAN OLIVE OIL NOT ACCEPTABLE FOR N. N. R.

The Council on Pharmacy and Chemistry reports that Pompeian Olive Oil was presented by the Pompeian Corporation for inclusion in New and Non-official Remedies. The Council explains that the product might be recognized as a brand of olive oil, U. S. P., marketed under the pharmacopeial name ("Pompeian" being used merely to identify the firm's brand) were it not that claims of unique advantage and therapeutic potency were advanced. The Council cannot admit in reference to this brand of oil the claim made that the "ease of its digestion and assimilation is far greater than that of any other vegetable or animal oil." After considering the evidence submitted by the proprietors, the Council decided that Pompeian Olive Oil is not acceptable for New and Non-official Remedies. (Jour. A. M. A. July 5, 1930, p. 35.)

UNIVERSITY NEWS

REPORT OF THE DEAN OF THE MEDICAL SCHOOL

To the President of the University of Minnesota

Sir:

I have the honor to submit the report of the Medical School for the biennium, 1928 to 1930.

FACULTY

Deaths.—On March 8, 1929, occurred the death by suicide of Dr. C. J. V. Pettibone, Associate Professor of Physiological Chemistry. Dr. Pettibone, A.B. University of Chicago, Ph.D. Harvard, several years of foreign study, had been connected with our school since 1912. As teacher and as Secretary of the Student Work Committee he rendered good service.

On April 3, 1930, Dr. C. Eugene Riggs, aged 77, Emeritus Professor of Nervous and Mental Diseases, died at his home in St. Paul. He was the pioneer of his specialty in the Northwest, was connected with the School from 1889 to 1913, and again gave active teaching service during the World War.

Resignations, Appointments.—Dr. Arthur A. Law, Associate Professor of Surgery since 1913 and connected with the department since 1899, resigned December 21, 1929. His services as teacher and as surgeon at the University Hospital were not only long in years but of high quality. There was never a time, day or night, when he was not ready to respond to an emergency call. His resignation was regretted by the department of surgery and the administration. By special vote of the Board of Regents a certificate of appreciation setting forth his services to the school, his honorable army record, his high standing in the profession and among the alumni of the University, was engrossed and presented to Dr. Law.

In June, 1929, Dr. Thomas Lee, Professor of Anatomy, former Director of the department, having reached the age limit, retired from active duty and, after a farewell dinner participated in by a great body of friends, moved to Florida. He had been on the faculty since 1891, and a host of students remember him with pleasure.

Dr. Fred L. Adair, Professor of Obstetrics and Gynecology, Chief of the service in these branches at the Minneapolis General Hospital, teacher and investigator of distinction, on our faculty since 1905, resigned October 1, 1929, to accept a professorship at the University of Chicago.

Dr. Frederick W. Schlutz, Professor of Pediatrics and Head of the Department, resigned April 1, 1930, to accept also a professorship at the University of Chicago. Dr. Schlutz had been a member of the teaching staff since 1910 and head of the department since 1924. He is recognized as distinguished in his specialty, as is evidenced by his call to his new position.

The resignations of Drs. Adair and Schlutz were prompted by the better salaries and opportunities offered by a heavily endowed university. It was with regret that we found ourselves unable to retain their services.

On January 1, 1930, Dr. A. C. Strachauer, Professor of Surgery and Head of the department, in accord with an arrangement entered into three years before, retired and Dr. Owen Wangensteen took his place Dr. Wangenteen, our graduate, M.D. 1922, Ph.D. 1925, has been preparing himself through more than ten years for a university career in surgery. During the three years mentioned he spent fourteen months abroad on university salary and the rest of the time mostly in our own clinic. He takes up his work as head of surgery under the full-time plan. Dr. Strachauer has also resigned as Director of the Cancer Institute but will remain on the faculty with rank of professor on the unsalaried basis. We thank Dr. Strachauer for his years of service in the school of which he is an honored alumnus.

The appointment of Dr. Leo Rigler, M.D. 1920, as Chief of the *x*-ray department, although it occurred before this biennium, may be referred to as another example of the wise choice of a promising graduate, his advanced preparation in his specialty in part at University expense and his promotion while still young to a responsible post. This method of filling the faculty is justifying itself.

The place of Dr. Lee was filled by the transfer from the Department of Zoology to the Department of Anatomy of Professor Hal Downey, distinguished authority on blood, whose investigative work in recent years had brought him gradually into the medical field. The change of departmental affiliation was therefore appropriate, but the School expresses a debt to the Zoology group for relinquishing so valuable a colleague.

The post of Dr. Adair at the General Hospital, with its important teaching duties, was filled by the promotion of Dr. John A. Urner from Instructor to Assistant Professor and his assignment to that institution. He is one of the capital young men who have trained here in the last few years and have adopted medical academic careers instead of private practice. We were fortunate to have such a man available.

Without permitting the school to become inbred it is the desire of the administration to have a good proportion of our own graduates on the faculty. However, in the case of the vacancy in Pediatrics it was thought that our local alumni would be more valuable as part-time men in the department, bringing to it the point of view of active practice, and the choice for the headship fell upon Dr. Irvine McQuarrie, Associate Professor of Pediatrics, Rochester (New York) University School of Medicine. Dr. McQuarrie, 39 years old; A. B., Utah; Ph.D., California; M.D., Johns Hopkins; Instructor, Yale; Head of Pediatrics Henry Ford Hospital; at Rochester since 1926, has published important contributions in his field, has a fine record as a teacher. He will take charge in August 1930.

In order to be with her aged mother, Miss Marion Vannier, Associate Professor of Nursing and Director of the School of Nursing, has resigned as of August 31, 1930. Miss Vannier, graduate of Johns Hopkins School of Nursing, came to the University Hospital in

1916, later was Superintendent of Nurses at the Miller Hospital, later still Superintendent of Nursing in the University Hospital, became Director of the School in 1924. Miss Vannier is an expert in nursing education and administration, and the school has prospered under her direction. We regret to have her leave the University.

Miss Katherine Densford, A.B. Miami, A.M. Chicago, Graduate of the Cincinnati University School of Nursing and Assistant Dean in the Cook County Hospital School of Nursing, has been elected to succeed Miss Vannier.

Absences on Leave.—The School was honored by the selection by the Rockefeller Foundation of Dr. Hilding Berglund, professor of medicine, as visiting professor at the Pekin Union Medical School, for the year 1928-29. Dr. Berglund returned to duty July, 1929.

Dr. J. C. McKinley, Professor of Nervous and Mental Diseases, was on sabbatical leave, 1928-29, studying chiefly at Breslau, Germany.

Dr. William Swanson, Associate Professor of Pediatrics, has spent his sabbatical, 1929-30, at Johns Hopkins University.

Intrauniversity Faculty Relations. — The Medical School is proud of the contributions made by its members to the broad problems of the whole University and mentions particularly the important work done by Professor R. E. Scammon* in connection with the Insurance Plan for the faculty and employees recently adopted by the Board of Regents.

ENROLLMENT

The details of student registration will be found in the Registrar's report. Suffice it here to say that the number of medical students averages about 135 in each of the four classes with an equal number in the fifth or intern year required for the M.D. degree.

We take one hundred into the Freshman class each fall, selecting them from 300 or more applications. In place of the "Unclassed" group formerly accommodated we now take 40 additional Freshmen on January 1. These students take as their official freshman year the winter, spring and summer quarters and in the fall join on equal terms the 100 fall quarter freshmen of the previous year to make up the Sophomore class.

Our number of students makes this the second largest medical school in the country. We feel the number is too large for the best results of teaching, notwithstanding our continuous use of facilities throughout the year under the four quarter system.

We feel further that the policy of preference to Minnesota residents prevents to a certain degree the selection of the most promising material from our large number of applicants. Most applicants residing outside the state have to be rejected, regardless of qualification. From the standpoint of securing the best prepared and most cosmopolitan student body the policy of Indiana University that its Medical School exists to prepare physicians for the state seems preferable to our presumably accepted theory that the Medical School exists to educate the children of the taxpayers.

These remarks on student enrollment concern themselves with medical students only. It is to be recalled that the Medical School administers also the Nursing School curriculum and the Medical Technicians curriculum. The enrollments in these courses are available in the Registrar's Report and other details will be found in the reports of the directors of these activities appended hereto.

The policy at Minnesota is that the Medical School, through its departments, teaches all students who need its disciplines as part either of a general education or of professional training. Consequently large numbers of students of Home Economics, Dentistry, Physical Education, Agriculture, Pharmacy, the Graduate School, etc., receive part of their training in the Medical School. These enrollments are naturally classified elsewhere.

COMPREHENSIVE EXAMINATION SYSTEM

During 1929-30 the Faculty has worked out and put in operation a system of examinations by which progress in the medical curriculum is made not by passing examinations on single courses but by a single examination on all the work of a given year. The thought is that the student should regard his education in terms of a large objective, should demonstrate capacity to keep in mind the essential substance of an entire year's work. Each year's examination is in charge of a special committee. The administration of all examinations is centralized. Dr. A. T. Rasmussen of the Department of Anatomy has done a noteworthy service as Chief Examiner. The first trial of the system this spring convinces the various committees that the comprehensive examination has advantages and that the number of failures, though distributed differently, is not increased over the old system.

NEW HOSPITAL UNITS

The completion in the fall of 1929 of the Eustis Children's Unit, the Out-Patient Unit and the Students Health Unit greatly increased and improved our teaching facilities along clinical lines. The number of hospital beds was increased to about 400, with adequate and beautiful quarters for children. The modern outpatient quarters led very soon to a distinct increase in number of patients available for this useful type of teaching. The bringing of the Student Health service to the Medical campus and its integration so far as bed patients are concerned with the University Hospital, have improved the Health Service, unified the University's hospital activities and brought the significant values of the Health Service as a community health movement more to the attention of future physicians.

READJUSTMENTS IN MILLARD HALL

The transfer of the out-patient service to its new quarters in the hospital group vacated considerable space in Millard and enabled the scientific departments therein to expand. Pharmacology in particular, which

*Since this was written Dr. Scammon has resigned to accept a position at the University of Chicago. This is a heavy loss to the University.

has been housed for fifteen years in Physiology space, gets adequate and convenient quarters in the north wing. Building changes essential to these readjustments are just being completed.

RELATIONS WITH THE MEDICAL PROFESSION

These relations have become measurably more harmonious and coöperative in this two year period. Three movements have contributed to this result.

The Alumni have become more active. Their Advisory Committee meets regularly with the Dean and Hospital Superintendent to consider school matters. During the meeting of the American Medical Association in Minneapolis in June, 1928, the alumni of our school held the largest meeting and banquet in the history of the School. Perfecting their organization they have instituted a clinical program each fall at Homecoming. The first was realized in 1929 and was satisfactorily attended. The entire program was put on by alumni, Dr. Otto Folin, distinguished biochemist of the Harvard Faculty and Minnesota graduate, being the guest of honor. Through these meetings an increasing number of alumni gain insight into the aims and problems of the School. To Drs. O. S. Wyatt and N. O. Pearce we owe much of value coming out of alumni interest.

The second activity contributing to better relations with the profession has been the Extension courses for physicians. While administered by the Extension Division the actual teaching has naturally fallen upon members of the Faculty. Weekly series of lectures of topics of value to medical men are offered in any part of the state when a center of interest exists. A considerable number of such courses have been completed and others arranged for. The State Medical Association contributes and coöperates. Dr. N. O. Pearce is largely responsible for the success attained. Of the full time staff Dr. W. A. O'Brien has contributed much time and effort to work among the doctors. We owe all these gentlemen a great debt. To various other participating Faculty members we give best thanks for a largely unpaid but very valuable service.

In this connection should be mentioned the informal consultation service developed as another joint activity of the Medical School and State Medical Association. This idea, again, emanates from Dr. Pearce, now President of the Medical Alumni; and Dr. W. A. O'Brien, Pathologist of the University Hospital, active publicist and tactful adjuster of difficult situations, is again the man selected to conduct the machinery by which doctors in rural practice can get expert information on troublesome cases. Dr. O'Brien on account of his peculiar abilities and on account of his position is also the choice of the State Association as radio speaker for the profession. This is an important educational effort. We are proud to have such a man as Dr. O'Brien available for activities like these just described.

Thirdly, as a factor in bettering relations with the profession and throughout the state should be mentioned the work of Mr. Paul Fesler, Superintendent of the University Hospital, among the doctors and county officials. He spends a good deal of time in the various districts and strives to make the hospital more useful both to physicians and to the sick poor. Through Mr. Fesler's efforts and with the invaluable help of Dr. Herman Johnson and Dr. C. B. Wright—to name but two of numerous influential physicians interested in the matter—the appropriation for the University Hospital has been separated from the general University appropriation and increased. Inasmuch as the hospital is chiefly justified, in popular view, as a service institution this arrangement is fairest alike to legislature, taxpayers and the University as a whole. Too much praise cannot be accorded Mr. Fesler for his kindly, tactful, diligent efforts to bring the hospital in accord with the ideals of the profession and increase its effectiveness as a central institution for unfortunate citizens.

RESEARCH

This school has always carried on active research along various lines. The program has been stimulated and expanded in the biennium by the special appropriation of $25,000 a year for medical research granted by the last two legislatures. This fund is apportioned to various projects advanced yearly by interested members of the faculty. More and more funds from outside sources are becoming available by gifts of individuals and corporations for special projects. Several departments publish their papers yearly as bound volumes of reprints. In a brief report details cannot be set forth. Those qualified to judge consider the quality and number of our publications as placing us among the noteworthy medical schools in this respect.

SYMPOSIUM

Early in 1929 the Director of the Summer Session proposed that funds be devoted to a limited number of special projects outside the ordinary routine of class work. Taking advantage of the fact that the International Physiological Congress was to meet (for the first time outside of Europe) in Boston in August, the Medical School and agricultural biochemical groups proposed that a Symposium on Physiology and Physiological Chemistry be held at Minnesota. The plan was approved and carried out July 15 to August 15. Distingushed foreign scientists contributing were Prof. M. von Frey, Wurzburg; Prof. T. Thunberg, Lund; Prof. E. Laqueur, Amsterdam; Prof. E. Waldschmidt-Leitz, Prague; Prof. G. V. Anrep, Cambridge. Several well-known Americans and our own men also participated. Attendance at these lectures was good. A large amount of interest was stimulated. The project will be continued this summer by a Symposium on "The Kidney in Health and Disease," July 7-18, under the chairmanship of Prof. Hilding Berglund.

ADVANCED STUDY

Graduate work in medical subjects and the training of medical graduates as specialists comes under the Graduate School and is reported by the Dean of that School. In this place is noted only that the number of such students getting training in the Medical School and under its faculty is increasing. Our men are going

out to good posts in other universities and filling vacancies in our own faculty. Some go to the higher walks of practice. The presence of the graduate group is stimulating in undergraduate education. The Medical School is proud of its participation along with the Mayo Foundation in the largest existing experiment in medical graduate education.

CONCLUSION

Taken broadly it is believed this review of its activities demonstrates that the Medical School is continuing its useful function as a teaching and investigative mechanism, has gradually strengthened its facilities and man force in the last two years, has widened its influence in the state and has contributed to the prestige of the University.

Respectfully submitted,

E. P. Lyon, *Dean.*

June 30, 1930.

MISCELLANEOUS

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

HEARING HELD ON RIGHT OF MASSEUR TO USE TITLE OF DOCTOR

On July 21, a hearing was held before the State Board of Medical Examiners to determine whether or not the license of a masseur who was using the title of "Doctor" should be renewed for the year 1930. Masseurs under the 1929 Massage Law are prohibited from using the title, "Doctor."

The masseur in this case, however, who maintains an office in Minneapolis, refused to comply with the law and appeared in person before the Board together with his attorney. After a very thorough hearing on the matter the State Board of Medical Examiners unanimously voted to refuse to renew the license unless within ten days thereafter the applicant removed his signs and complied with the law. On a check-up of the case at the end of ten days it was found that all the signs had been removed.

The indiscriminate use of the title, "Doctor," was one of the outstanding complaints made about the non-enforcement of the previous Massage Law and resulted in a repeal of that law at the 1929 Session of the Legislature. By their action in this case the State Board of Medical Examiners has served notice that it intends to enforce the Massage Law as well as the Medical Practice Act and Basic Science Law.

RICKETS AND VITAMIN D

Without detracting in the least from the market value of viosterol in the treatment of rickets, certain recent investigations raise a question as to the simplicity of the pathogenesis of rickets implied in the current use of viosterol. It has been pointed out recently that, whereas both viosterol and cod liver oil are extremely efficacious in curing rickets, only the latter contains in addition the indispensable Vitamin A. Although the most obvious function of calcium and phosphorus is in the building of bones, there are other demands for these mineral elements which, at times, become of great importance, and it has been shown that, whereas Vitamin D is concerned with the calcification of bones, the retention of calcium and phosphorus in the body is largely a function of the level of these materials in the diet. A comparison of the efficacy of cod liver oil and of viosterol as prophylactic antirachitic agents showed that of 123 children given viosterol 29 per cent were not protected against rickets, while of 100 given cod liver oil 3 per cent showed rickets, although the former group received twice the number of units of Vitamin D given the latter group. (Jour. A. M. A., July 5, 1930, p. 38.)

DESICCATED PITUITARY PREPARATIONS OMITTED FROM N. N. R.

In 1928 the Council on Pharmacy and Chemistry discussed the lack of acceptable evidence for the value of pituitary preparations administered by mouth and concluded that extensive clinical experience had failed to establish the value of desiccated pituitary preparations for oral administration. At that time the Council decided to omit such preparations when the period for the acceptance of the products included in New and Non-official Remedies should expire, unless new evidence became available in the meantime permitting a different action. At the expiration of this period no favorable evidence had become available. Accordingly the Council has directed the omission of all desiccated pituitary preparations now included in New and Non-official Remedies, namely: Desiccated Pituitary Body-Armour, Desiccated Pituitary Substance (Anterior Lobe)-Armour, Desiccated Pituitary Substance (Posterior Lobe)-Armour, Anterior Pituitary Desiccated-Lederle, Posterior, Pituitary Desiccated-Lederle, Whole Pituitary Desiccated-Lederle, Pituitary Body Anterior Lobe Desiccated-Mulford, Anterior Pituitary Desiccated-P. M. Co., Pituitary Substance-Desiccated-P.M. Co., and Posterior Pituitary Desiccated-P. M. Co. (Jour. A. M. A., July 19, 1930, p. 201.)

SUPER D BRAND COD LIVER OIL

The Upjohn Company markets a product "Super D Brand Cod Liver Oil." The advertising that is issued for this preparation reads as if the product were cod liver oil fortified by the addition of irradiated ergosterol. The Upjohn Company has not requested consideration of the preparation by the Council on Pharmacy and Chemistry and so far the Council has not reported on it. The Council has announced the acceptance for New and Non-official Remedies of the following brands of cod liver oil with viosterol 5 D: Abbott's Cod Liver Oil with Viosterol 5 D (Abbott Laboratories); Parke, Davis & Co.'s Cod Liver Oil with Viosterol 5 D (Parke, Davis & Co.); Squibb's Cod Liver Oil with Viosterol 5 D (E. R. Squibb & Sons); Squibb's Cod Liver Oil with Viosterol 5 D, Mint Flavored (E. R. Squibb & Sons). (Jour. A. M. A., June 14, 1930, p. 1939.)

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

RELATIVE PROPHYLACTIC VALUE OF CONVALESCENT AND IMMUNE ADULT MEASLES SERUMS: E. Garrido Morales, M.D., Epidemiologist, and O. Costa Mandry, M.D., C.T.M., Director, Biological Laboratory, San Juan, Porto Rico (Amer. Jour. of Dis. of Children, Vol. 39, No. 6, June, 1930). The prophylactic use of convalescent measles serum with good results has been reported by various investigators.

The use of immune adult serum in the prophylaxis of measles has also been encouraged, but little evidence is found in the literature regarding the true value of this agent.

Data are presented in this paper which give immune adult serum, in proper doses, a definite place in the prophylaxis of measles.

Of 120 children exposed to measles by familial contact and immunized with convalescent serum, 102, or 85 per cent, were completely protected. Fourteen of the eighteen attacked in this group developed attenuated measles.

Of 132 children also exposed to the disease by familial contact and immunized with doses of from 20 to 40 c.c. of immune adult serum, 108, or 80.3 per cent, received complete protection and 20 of 26, or 76 per cent, of those attacked developed attenuated measles.

Doses of 10 to 15 c.c. of adult serum gave complete protection in less than 50 per cent of the persons immunized, but usually resulted in an attenuated or mild form of the disease.

Of 183 untreated children (controls) living in the same houses with patients who had clinical cases and with treated children, only thirty-four, or 18.6 per cent, failed to contract the disease. Only two children had mild reactions among more than 500 who received treatment with serum. It appears likely that a serious obstacle to the widespread use of convalescent serum will be the objection of some parents to the immunization of their children with serum obtained from strangers. Immune adult serum is readily and universally available, and the technic for obtaining it from adults or children who have had the disease is simple and does not involve any risk. Immune adult measles serum should be used with greater frequency for the protection of exposed children, especially for debilitated children, who probably die from the disease.

EYE, EAR, NOSE AND THROAT

SOME NON-SURGICAL AIDS IN THE TREATMENT OF GLAUCOMA: S. R. Gifford (Brit. Jour. of Ophthalm., Vol. XIII, No. 10, p. 481, Oct., 1929). Nearly all cases of glaucoma will at some time require surgical interference, and this should be done early, but in acute inflammatory and other conditions, it is necessary to postpone operative procedure for some time. In doing so it must be remembered that the visual fields and vision must be as carefully watched as the tension; also, that the tension varies during the day, it usually being higher in the morning.

Miotics should be tried in most cases, and these should be given frequently enough to keep the tension normal if possible. Eserine if used constantly often causes a conjunctivitis, so it may be necessary to alternate with pilocarpine and occasionally dilate the pupils for a short time with homatropine, to prevent the formation of adhesions.

Some of the newer methods may be used if further delay is necessary and high tension persists or as a pre-operative measure. Glaucosan is a dextro-rotatory adrenalin which shows no constitutional reactions on sub-conjunctival injection. A 2 per cent solution of ordinary adrenalin if instilled several times during an hour produces a mydriasis as great as that developed by subconjunctival injection of the 1/1000 solution. These are contra-indicated in the presence of any severe ocular inflammation. Their use is limited mainly to cases of simple glaucoma. Miotics should be instilled before using these and also immediately afterward, keeping the pupil well-constricted. The glaucosan is instilled (not injected) three to five times,

at fifteen minute intervals. Cotton pledgets soaked in 1/1000 adrenalin may be used under the upper lid, first anaesthetizing with butyn. The same results may be better obtained by a sub-conjunctival injection of four or five minims of the 1/1000 adrenalin. In a series of fifty cases all but fifteen showed an appreciable decrease of tension. The amount of decrease varies as well as the duration. In some cases the reduction lasts a month or longer with continued use of miotics. The vaso-neurotic type of patient responds much the best.

Amino-glaucosan is a 10 per cent histamin solution which rapidly contracts the pupil but frequently does not reduce the tension. It also has the disadvantage of frequently causing an inflammatory reaction.

Intravenous use of hypertonic saline solutions may reduce tension considerably by causing absorption of fluids from all the tissues, including the eyes, into the blood stream. It is especially useful pre-operatively in acute cases, or combined with miotics when they alone fail.

Some good but a variable reduction of tension has been reported in using ergotamine. This may be given sub-cutaneously or by mouth in doses of 1/60 to 1/30 of a grain. This drug has no effect on acute glaucoma and its use must be continued over a considerable period of time. It raises the blood pressure and depresses the sympathetic nerve endings. It is used in glaucoma on the idea that hypertension is caused by hyperactivity of the sympathetic system and that such a drug would diminish vessel permeability.

RECURRENT HEMORRHAGES INTO THE RETINA AND VITREOUS—CALCIUM DEFICIENCY AS A POSSIBLE CAUSE: Charles A. Young. (Trans. of Amer. Acad. of Ophthal. & Otolaryng., 1929, p. 191). In one of the three cases reported, low blood calcium seems to be definitely the cause of recurrent hemorrhages. This patient had eight hemorrhages in the past three and a half years. Blood calcium was 6.5 mg. per 100 c.c. The following treatment was instituted for a period of three weeks out of every three months:

Gluco-Calx 5 c.c. intravenously twice a week.
Parathyrin 1 c.c. intra-muscularly twice a week.
Thyro-Calx tablets, 1 t.i.d.

There were no hemorrhages for the next two years.

The early hemorrhages seem to clear up rapidly, but in cases of repeated hemorrhages the vision is usually lost as a result of proliferating retinitis and detachment of the retina.

There seems to be many causes for repeated retinal hemorrhages and it might well be that two or more factors are present, but calcium deficiency should always be considered as a possible cause.

L. G. Flanagan, M.D.

REMOVAL OF LEAD SHOT FROM THE VITREOUS: George H. Cross. (Trans. of Amer. Acad. of Ophthal. and Otolaryng., 1929, p. 173). Vision even to 20/20 can be saved by removal of lead shot from the vitreous, with a pair of wire forceps and a double plane fluoroscope. The attempt at removal should be made at once, otherwise the formation of exudates makes the removal more difficult.

In June, 1927, the first successful removal of a No. 6 shot was reported. This resulted in poor vision (light perception), but saved the eye-ball.

A foreign body in the eye-ball is a critical injury and may result in a vitreous abscess, plastic inflammation, degenerative iridocyclitis, detached retina or phthisis bulbi.

It is difficult even with modern devices to localize a foreign body to within less than 2 or 3 mm. The instruments used must be short because of the close proximity of the fluoroscope. Incision is made through the sclera after the shot has been localized; then forceps are inserted and guided by the fluoroscope. After removal, the sclera is sutured and atropine is instilled. Of the four cases, in two of the foreign bodies were in the orbital tissue. In only one of these cases was the shot removed. In the other two, the foreign bodies were in the vitreous and were removed in both cases, resulting in one case in a vision of 20/20.

CAPITAL PUNISHMENT

I am not a proponent of capital punishment, though I am certain, if it were really used all over the United States it would be a deterrent to murder. When anyone says to me that it is not, I cease to listen to him for he simply does not think. Capital punishment is not really used any place in the United States. Certainly in nations where murderers are morally certain that they will be caught, convicted and executed, the list of murders is infinitely smaller than in these United States. Let me just quote what a bandit murderer said to me in a state where capital punishment is legal: "If you have to kill a guy in the course of doing your work, the chance are four to one that you won't get caught. If you are caught, the chances are two to one that you won't be convicted. If you are convicted the chances are four to one that you won't get hanging. And if you do get hanging, the chances are four to one you'll get a commutation to life, before you're hung, and if you get a commutation, you'll serve less than ten years if you behave yourself in prison." And he knew his statistics in this particular state. If that is using capital punishment as a deterrent, we have changed the meaning of the word "use." We must see to it that the crime of murder is treated properly to protect society from the gun man.—Rev. Don Frank in *Quarterly of American Interprofessional Institute,* June 1930.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

EDWARD JENNER AND THE DISCOVERY OF SMALLPOX VACCINATION. Louis H. Roddis, Lieutenant Commander, Medical Corps, U. S. Navy. 155 pages. Illus. Price $1.00. Reprinted from The Military Surgeon. Menasha, Wis.: The Collegiate Press, George Banta Publishing Co., 1930.

MEDICAL AND SURGICAL YEAR-BOOK. Physicians Hospital of Plattsburgh, N. Y. 322 pages. Illus. Price $3.50. Plattsburgh, N. Y.: The William H. Miner Foundation.

CLINICAL LABORATORY METHODS (Third Edition). Russell Landram Haden, M.A., M.D., Professor of Experimental Medicine, University of Kansas, School of Medicine. 317 pages; 69 illustrations and 4 color plates. The C. V. Mosby Company, St. Louis, 1929.

As a former laboratory director and teacher in clinical microscopy and later a research man and internist, the author is peculiarly fitted to prepare a book of this kind. He claims it to be "in no sense a textbook" but a working manual for the clinical laboratory of a general hospital. The reviewer is impressed with the brief and clear presentation of each procedure without unnecessary discussion, the omission of unimportant and obsolete methods which ordinarily waste pages of like books on laboratory methods and the later and more authoritative references given to each technic to which the student may refer.

The book is manifestly a working guide for a busy clinical laboratory which is fortunate enough to enjoy the full coöperation and patronage of the internist who appreciates the real value of the well executed laboratory aid. As such, this book has a definite and useful place in the reference library of a clinical laboratory.

KANO IKEDA, M.D.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

EXPERIENCED LABORATORY TECHNICIAN and nurse wishes position in clinic, doctor's office, or hospital. Address D-97, care MINNESOTA MEDICINE.

WANTED—Locum tenens or assistantship by experienced physician, licensed in Minnesota. Address D-98, care MINNESOTA MEDICINE.

WANTED—1927 University of Minnesota graduate desires permanent location in Minnesota. Has been doing general practice and assisting surgeons since graduation. Age 33. Married. Can arrange interview. Address D-94, care MINNESOTA MEDICINE.

WANTED—Young lady 21 years old wishes position in doctor's or dentist's office. High school graduate, nurse's training, typewriting. Address D-95, care MINNESOTA MEDICINE.

PHYSICIAN'S OFFICE FOR RENT—Best location Midway district, corner Thomas and Hamline, Saint Paul. Rent $25.00 a month. Inquire at dentist's office.

THE USE OF SEVERAL NEW DERIVATIVES OF BARBITURIC ACID*

JOHN S. LUNDY, M.D., and CLAUDE F. DIXON, M.D.
Rochester, Minnesota

AT THE present time derivatives of barbituric acid are considered as valuable drugs for surgical and nonsurgical purposes. Their value has not been wholly determined but most surgeons are agreed that from the standpoint of postoperative complications, small or hypnotic doses are to be preferred to large or anesthetic doses.

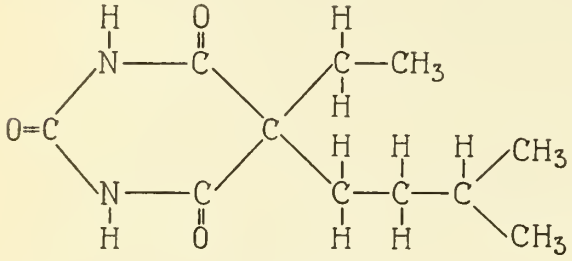
Since each of the barbiturates produces a somewhat similar effect,[1] we shall describe briefly the effect of various doses of sodium *iso*-amylethyl barbiturate (sodium amytal) on the average patient. The factors which change the patient's tolerance for the drug obviously cause variations in the effect.

SODIUM *iso*-AMYLETHYL BARBITURATE (SODIUM AMYTAL)

Sodium *iso*-amylethyl barbiturate has been used at The Mayo Clinic in approximately 2,000 cases in the period from April 1, 1929, to April 1, 1930. The conclusions reached are based on 1,712 of these cases. The drug has been used intravenously in 753 cases, rectally in twelve cases, and orally in the remainder. The most common serious untoward results following the use of a barbiturate are pulmonary edema and bronchopneumonia. It is probable that ultimately small doses must be resorted to since these untoward effects seem to be associated frequently with large doses. Pulmonary edema and bronchopneumonia must be treated early by oxygen, or oxygen and carbon dioxide, with or without the intravenous administration of concentrated solution of glucose.

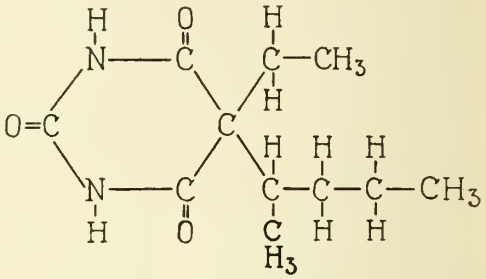
Because of the relationship between dosage and effect in the average healthy adult, the subject of dosage will be taken up under four headings, representing the four stages of effect during and after the administration of sodium *iso*-amylethyl barbiturate.

In the first, or hypnotic stage, nystagmus, some vertigo and a feeling of inebriation will be produced by the administration of 4 to 6 grains (0.24 to 0.4 gm.). From 7 to 9 grains (0.45 to 0.6 gm.) may produce mild mental excitement. The patient usually answers questions readily until 5 or 6 grains (0.3 to 0.4 gm.) have been given. After about 10 to 12 grains (0.65 to 0.78 gm.) the average patient is unable to answer questions. Ordinarily there is no memory for events after this dose.



The second stage, that of inebriation, is induced by a dose of from 12 to 16 grains (0.78 to 1.065 gm.). In this stage, the patient responds to painful stimuli. The untoward result in this stage is restlessness.

In the third stage, as the dose exceeds 15 or 16 grains (1.0 or 1.065 gm.) a state of surgical anesthesia begins to develop. In this stage the systolic blood pressure falls from normal to about 90 or 80 mm. of mercury; shallow respiration, slight cyanosis, and a tendency for the tongue to fall back frequently occur. The fall in blood pressure is somewhat proportionate to the rate of injection, in that the more rapid the injection the more rapid the resulting fall in blood pressure. When hypertension is present one may expect about twice as great a fall in blood pressure as when the blood pressure is normal. We find it best to discontinue injection of the drug when



*From the Section on Anesthesia and the Division of Surgery, The Mayo Clinic. Read at the meeting of the Minnesota State Medical Association in Duluth, Minn., July 16, 1930.

the systolic blood pressure has become 85 mm. of mercury or less.

In the fourth stage the dose is between 45 and 100 grains (3.0 and 6.65 gm.). The untoward results incident to the use of various large doses are evidenced by interference with all reflexes.

Amytal

Embutal

Fig. 1. Chemical structure of *a*, *iso*-amylethyl barbituric acid and of *b*, ethyl 1-methyl butyl barbituric acid. One drug is the isomer of the other.

The sequence of events following the administration of this drug is relatively the same regardless of the tolerance which may exist; the proportion between different doses for different stages of effect remains about the same.

Sodium *iso*-amylethyl barbiturate has been used successfully by us as an antispasmodic in convulsive conditions such as tetanus, as an aid to withdrawal of alcohol in postoperative psychosis, in controlling a patient with acute mania, and in one instance for cesarean section. In the last case, the infant cried on being lifted from the uterus. At present this agent is being given to a patient who is dying from an inoperable lesion of the brain, with considerable relief. The patient has required about 3 grains (0.2 gm.) of the drug by mouth each hour for a period of about four months and has consumed, in that time, more than 9,000 grains (600 gm.).

It has been our observation that for the average adult, regardless of age, sex or weight, about one or two hours' noticeable effect for each grain of sodium *iso*-amylethyl barbiturate administered may be expected, especially if other medication has been omitted.

SODIUM ETHYL 1-METHYL BUTYL BARBITURATE (SODIUM EMBUTAL)

From March 4 to July 15, 1930, the sodium salt of ethyl 1-methyl butyl barbiturate (Fig. 1), one of the isomers of *iso*-amylethyl barbiturate was used in 705 cases, intravenously in 114 cases, orally in 575 cases, and rectally in 16 cases. This derivative of barbituric acid is essentially antispasmodic and sedative, and differs from sodium *iso*-amylethyl barbiturate in that there seems to be less delirium incident to its use and that an equivalent effect may be produced with about half as much as with sodium *iso*-amylethyl barbiturate.

Sodium ethyl 1-methyl butyl barbiturate may be used in dilute solution since its potency is high. We have used it in 6.66 per cent solution, 1 grain (0.065 gm.) to 1 c.c. The maximal dose has been 7.5 grains (0.482 gm.). The average dose has been 3 to 5 grains (0.2 to 0.3 gm.) administered in three to five minutes. It seems to be particularly valuable in preparing patients for operation and satisfactory sedation has been obtained regardless of whether the final anesthetic desired is local, general, or both, from the administration of from 1.5 to 4 grains (0.097 to 0.24 gm.) of this agent by mouth, together with 1/6 or ¼ grain (0.01 or 0.015 gm.) morphine sulphate by hypodermic injection, about thirty-five to forty-five minutes before operation.

We have found that in connection with many of the general and local anesthetics a better result may be obtained with the sodium salt of ethyl 1-methyl butyl barbiturate or of *iso*-amylethyl barbiturate than with the other barbiturates we have used, and that less local or general anesthetic is required.

We believe that the morbidity, if not the mortality, incident to the administration of general anesthetics and possibly of local anesthetics may be materially reduced by the use of preliminary medication with these barbiturates. These prep-

arations seem to allay fear, thereby keeping the patient's tolerance normal for the anesthetic that is to be used.

Sodium *iso*-amylethyl barbiturate (sodium amytal) and sodium ethyl 1-methyl butyl barbiturate (sodium embutal) have been very useful in operations on the thyroid gland in that they make it possible for the operation to be done with local anesthesia and without the use of inhalation anesthesia. The patients may be awakened at any time during the procedure and one is able, therefore, to determine immediately if injury has occurred to either recurrent laryngeal nerve.

SPINAL ANESTHESIA: CONCLUSIONS BASED ON A STUDY OF 1,283 CASES*

ARNOLD JACKSON, M.D., F.A.C.S.
Madison, Wisconsin

SPINAL anesthesia was used in 2 per cent of the cases of major surgery performed at the Jackson Clinic in 1920; in 1928 the percentage had doubled; in 1929 it had increased to 71 per cent, and for the present year to date this anesthesia has been used in 80 per cent of the major operations.

Previous to 1928 spinal anesthesia was used only in selected types of operations at our clinic, such as prostatectomies and extensive resections of the bowel for malignancy. Although our staff has favorably regarded this form of anesthesia for a number of years, inability to govern the fall in blood pressure has prevented its use as a routine measure. However, the rediscovery of ephedrine by Chen, a Chinese student at the University of Wisconsin, and the demonstration of its action in preventing a fall of blood pressure in spinal anesthesia, as shown by Ockerblad and Dillon in 1927, served to eliminate this objectionable feature.

Meanwhile, through the efforts of Babcock, Jonnesco, Labat, and some of the European surgeons, spinal anesthesia was again winning more advocates. Shortly prior to the 1928 meeting of the American College of Surgeons, Pitkin, among others, called attention to the value of this anesthetic in routine major surgical operations performed below the clavicles. Such interest was aroused in this procedure that a considerable portion of this meeting held at Boston was given over to a demonstration and discussion of its advantages and disadvantages. Considerable apprehension was aroused because of a death that occurred at one of the clinics, and there were reports of several other fatalities that directly or indirectly might be attributed to the anesthetic. The literature of the past contains similar reports, but in the light of our present knowledge few if any of these deaths would occur.

Pitkin's demonstration of the ease and rapidity with which spinal anesthesia could be administered caused me to visit his clinic and observe the use of this anesthetic as a daily procedure. His method was introduced into the Jackson Clinic and tried for several months, but proved to be successful in only about 75 per cent of the cases. It was frequently necessary to complete the operation under general anesthesia. Unfamiliarity with Pitkin's methods possibly accounted for some failures. For the past year and a half a volume control technic, which will be demonstrated by Dr. Stout, with moving pictures following this paper, has been used. This method in which the novocaine crystals only are used, following a preliminary injection of ephedrine, has proved entirely satisfactory. It is used in all major operations performed below the clavicles, and has proved so successful that inhalation anesthesia has been discarded almost entirely save for certain minor operations and for lesions about the face and mouth in which local anesthesia is not satisfactory. We have used general anesthesia in less than 2 per cent of our cases in a series of 1,500 thyroidectomies.

COMPARISONS

In spite of the fact that spinal anesthesia has gained tremendous popularity in the past two years, it is still looked upon with considerable skepticism by many surgeons who are unwilling to give up the old established methods. Probably there is no group of individuals as hard to convince of the merits of a new procedure as the medical profession. Possibly this is the result of frequent failures following too exaggerated claims.

Ether has been the old reliable anesthetic so long and the one that could always be relied upon that it naturally will be the last to be abandoned. It is looked upon as a comparatively safe anesthetic and, as far as deaths upon the operating table are concerned, it undoubtedly is. Little account, however, is attached to the mortalities that

*From the Jackson Clinic, Madison, Wis. Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minn., July 16, 1930.

occur days or weeks later as the indirect result of ether complications. Certainly in our experience, while complications still occur, they do so considerably less frequently after spinal than following ether anesthesia. Our statistics indicate a considerable decrease in the number of postoperative sequelæ occurring from the fifth to the fifteenth day, such as acute dilatation of the stomach, ileus, pneumonia, and embolism.

CHART I

ANALYSIS OF 1,283 OPERATIONS PERFORMED UNDER SPINAL ANESTHESIA

Appendectomies	277
Cesarean sections	22
Cholecystectomies	97
Cystoscopies	120
Gastric and intestinal operations	72
Herniotomies (all types)	89
Laparotomies	39
Orthopedic (leg, hip, spine, etc.)	59
Pelvic	352
Prostatectomies and cystotomies	40
Radical breast amputations	8
Rectal	44
Miscellaneous	64
TOTAL	1,283

Nitrous oxide is an ideal anesthetic for short operations, but it does not afford the relaxation in major abdominal surgery that is obtained with spinal or even ether anesthesia. Furthermore, it so increases congestion and venous stasis as to frequently obscure the field of operation.

Along with many other clinics we have abandoned the use of ethylene because in our judgment it is incomparable as an anesthetic to local or spinal anesthesia, and because the surgeon should not be burdened with the responsibility of a possible explosion.

During the past year several other new anesthetics, or one might better say hypnotics, have received considerable attention. Of these sodium amytal has probably been the one most widely discussed and used in this country. Shortly after Zerfas and McCallum first reported the use of this drug, I had an opportunity of visiting their clinic and observing the effect of sodium amytal. The initial impression I received from observing the spectacular effect of a child going quietly to sleep within three minutes after the intravenous injection of the drug, was even greater than when I first observed Pitkin performing an open reduction of a child's femur under spinal anesthesia. After a year's study with sodium amytal in comparison to spinal anesthesia, however, I have come to the following conclusions:

With sodium amytal the patient is either unable to comprehend and coöperate, yet not sufficiently asleep to permit operating without the aid of nitrous oxide, or he is so deeply asleep that one is rather uneasy concerning his condition, while under spinal anesthesia the surgeon at all times has the patient's coöperation.

With sodium amytal it is impossible to have the patient cough or strain, frequently a valuable aid in doing a herniotomy. The addition of nitrous oxide causes the operating field to become more vascular and the risk of pulmonary complication is introduced.

CHART II

	1928 Aug. 1 to Dec. 31	1929 Jan. 1 to Dec. 31	1930 Jan. 1 to May 31
Operations in which spinal anesthesia was possible	342	1,253	498
Number given	79	893	346
Percentage	21	71	80

Delirium is frequently present so that the patient requires constant attention for hours following operation, an objectionable feature that is absent with spinal anesthesia.

In abdominal and pelvic operations relaxation is better than that obtained under inhalation anesthesia, but incomparable with that obtained under spinal anesthesia.

These comparisons are given in detail because at a number of meetings I have attended recently those present have been interested in the relative merits of these two methods of introducing anesthesia. Experience with sodium amytal was wisely limited to a small number of investigators by Zerfas and McCallum during the early months of trial. In spite of their precautions several fatalities may be directly or indirectly attributed to its use.

I have reached the conclusion that while sodium amytal will prove valuable, particularly as a hypnotic and as an anesthetic in certain operations about the face and mouth requiring the use of cautery, for major surgery, spinal anesthesia is greatly preferable. My observations on the use of avertin or tribromethanol, and pernoctin are limited, but in comparison with spinal

anesthesia I believe the same objections may be considered as with sodium amytal.

ADVANTAGES

In my opinion the introduction of spinal anesthesia into the daily operating routine is the greatest boon, not only to the surgeon but to the patient as well, that has taken place since the advent of aseptic surgery. The advantage to the patient is tremendous. If the operation is performed with average skill and within reasonable time the patient returns to his room almost as well as when he went to the operating table. Instead of being unconscious or even semiconscious with all the cells of the body drugged and the heart and lungs overtaxed, he is able to smile and talk to nurses and relatives. It is not unusual for the latter to be more perturbed than the patient. To prove how little the patient is affected by an operation we have even permitted a few to read or smoke.

From the hospital standpoint the problem of the after-care has been greatly simplified by the elimination of postoperative vomiting and unconsciousness. Relatives no longer spend anxious hours waiting for a patient to awaken from a prolonged inhalation anesthesia after a long operation. Fluids may be taken by mouth during and after the operation. There is no troublesome mucus in the throat, which is frequently present after an inhalation anesthetic. Since there is no retching or vomiting and consequent strain upon the wound, the patient suffers less postoperative discomfort and pain. Postoperative gas pains and distension are lessened because the intestines need not be forcibly walled off by sponges and handling.

The surgeon profits greatly. He is free from the worry of the ever-present danger of explosion. While close observation must be kept of the patient's condition, particularly as regards his blood pressure, yet there is less danger of sudden cessation of respiration than with nitrous oxide. Such occurrences are unusual in the experience of expert anesthetists, but the average hospital does not retain such highly trained anesthetists. If the blood pressure continues to fall after a spinal anesthetic in spite of the preoperative administration of ephedrine and adrenalin the repetition of either one or both of these drugs will control the situation.

As far as operative technic is concerned the surgeon's difficulties are immeasurably decreased. The abdominal wall, instead of being tight and rigid, is relaxed and the peritoneum can easily be lifted. When the latter is incised, the intestines do not well up into the wound but remain quiet and contracted, greatly simplifying the removal of a gangrenous or ruptured appendix or gallbladder, the release of an intestinal obstruction, or the anastomosis of the stomach and intestine. It is, of course, much easier to reach the source of trouble and eliminate it under these conditions. Closure of the wound is simplified by the relaxed abdominal muscles. Spinal anesthesia tends to eliminate the necessity for undue haste in any operation, since the patient suffers little shock. Patients stand long, critical operations far better under spinal anesthesia.

Some patients object to being awake during an operation, and it is simple enough to dull their sensations with the use of scopolamin and pantopon.

CONTRAINDICATIONS AND COMPLICATIONS

Spinal anesthesia is not devoid of danger if improper technic is followed, but we believe that fewer complications occur than with general anesthesia if the correct methods are used. In our first thousand cases there were no deaths which in any way could be traced to spinal anesthesia.

No patient has been refused this anesthesia during the past two years for any major operation performed below the clavicles. Cases of hypotension may be controlled by ephedrine. Central nervous system diseases such as brain tumor, or meningitis, neuro-syphilis, shock, and marked cardiac decompensation may be considered as contra-indications for spinal anesthesia.

Early in this series a number of postoperative headaches occurred, but with improvement in technic as developed by Stout and with the use of a small 22 gauge needle this objectionable feature has been almost eliminated. Postoperative pneumonia occurred in only three cases, although it was frequently necessary to perform emergency operations in the presence of acute respiratory conditions. Temporary paresthesias occurred in four cases among the first 1,000 patients, but have not occurred since. No permanent disability or lesion has resulted. The use

of ephedrine or adrenalin will check the fall of blood pressure and consequent nausea; carbon dioxide is a useful adjunct.

No attempt has been made in this discussion to cover the subject of technic which has been developed through the efforts of Labat, Jonnesco, Pitkin, Babcock, Koster and Stout. The latter in particular has done splendid work.

I wish merely to show the great satisfaction which we have obtained from using spinal anesthesia in our daily operative experience in the past two years. We are convinced that it is not a transient fad, as the experience of others as well as ourselves has shown it to be the most satisfactory anesthetic when properly used.

EYE, EAR, NOSE, AND THROAT ANESTHESIA*

L. W. Morsman, M.D., and Andrew Sinamark, M.D.
Hibbing, Minnesota

AS in operations in other fields, anesthesia for the eye, ear, nose, and throat may be divided into general and local. The technic of anesthesia in general is so amply covered in this symposium that it will not be taken up in this discussion. We will endeavor to bring out such modification as necessary for these special fields and to give the members of this association the results of our experience and conclusions drawn from the administration of anesthesia, both general and local.

GENERAL ANESTHESIA FOR THE EYE

Operations in the field of ophthalmology are so generally performed under local anesthesia that the subject of general anesthesia will need only brief discussion. There are times, of course, when any operation on the eye—cataract alone excepted—must be performed under a general anesthetic and in these rare instances ether is the anesthetic of choice. For short operations gas-oxygen anesthesia is used by preference. We use general anesthesia for small children and occasionally at the request of the patient having such major operations as enucleation. By use of a preliminary hypodermic of morphine even the "nervous type" of patient will usually be operated quite satisfactorily under local anesthesia. On account of the location of the work, special technic has to be used to keep the field sterile. After the patient is sufficiently under the anesthetic, the face is prepared and covered by sterile towels and gauze. The anesthetist may then render himself sterile or give the anesthetic while keeping himself well outside of the field of operation. This we accomplish by having the operator's assistant manage the head while the anesthetist uses a sterile towel so folded to fit over the nose, the remainder of the towel acting as a handle to the improvised cone.

LOCAL ANESTHESIA FOR THE EYE

We now limit our use of local anesthetics in the eye to the five following drugs: Cocain, butyn, novocain, holocain, and dionin. There have been introduced at various times numerous substitutes, such as eucain, acoin, stovain, alypin, and others. Our experience is that there are no real substitutes for the first five named.

Cocain is, of course, the outstanding anesthetic in ophthalmology. This is generally used in two and four per cent solutions. A drop of 4 per cent cocain every four minutes, for four or five instillations, will suffice for the average intraocular operation. Where there is congestion, sufficient adrenalin is used to counteract it. In operations on the globe, one drop of adrenal extract is usually sufficient. A 10 per cent solution of cocain is always kept on hand and is used in rare instances where the eye remains sensitive after the use of the 4 per cent solution. The 10 per cent solution is also valuable in strabismus operations to instill along the muscles after the conjunctiva is open and before manipulation of the muscles has begun. For injection for local anesthesia about the eye, we use 1 per cent cocain solution containing three to five drops adrenalin and use this for all purposes where no more than 1 c.c. of solution is required. This is particularly adaptable for extirpation of the lacrimal sac and plastic lid operations of minor degree.

Where infiltrations are made, novocain is used in place of cocain and in solutions from 1 to 2 per cent. For infiltration of any extent for plastic work, 2 per cent novocain solution is used in conjunction with the usual amount of adrenalin. Where large absorption may be expected, such as local anesthesia for enucleation, we use 1 per cent novocain with adrenalin.

Holocain in 1 per cent solution is used routinely only to anesthetize the cornea before taking readings of intraocular tension.

Butyn, in 2 per cent solution, we have found to be a very useful local anesthetic in office practice, for foreign body removal, and for minor operations upon the surface of the eye.

We have found dionin very useful for pain and irritation, particularly where the inflamma-

*Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minn., July 16, 1930.

tion is deep-seated and subacute or chronic. In cases of low grade iritis or uveitis, the patient is given a 2 per cent solution of dionin and instructed to use one drop three times daily in the painful eye. There is first an inflammatory reaction, followed by analgesia which may last for several hours. The eye establishes an immunity so that the strength of the solution is increased with each subsequent one-dram prescription. In some cases this may reach 10 per cent.

GENERAL ANESTHESIA FOR EAR, NOSE, AND THROAT

Ether is used for children under twelve, and occasionally is necessary for adults. With rectal or intravenous administration we have not had experience. We believe that gas-oxygen anesthesia for tonsillectomy has no place.

LOCAL ANESTHESIA FOR THE EAR

For anesthetizing the ear drum or skin of the external canal, we use a mixture of equal parts of cocain, phenol, menthol, glycerine and alcohol. A pledget soaked in this solution is left in the canal for fifteen minutes. This is suitable for polyps of the middle ear, and furuncles of the canal. For paracentesis of the drum, it is not reliable, and we prefer gas-oxygen anethesia.

LOCAL ANESTHESIA FOR THE NOSE

For all intranasal work, we use block anesthesia. Cotton applicators are soaked with cocain flakes moistened with adrenal extract. Two are inserted up to the roof of the nose, parallel to the outer slope. This blocks the anterior nasal nerve. Another pair are pushed back to the posterior tip of the middle turbinate to block the sphenopalatine ganglion. Before inserting these, the nose is sprayed lightly with a two per cent solution of cocain alternating with a 1:2,000 solution of adrenal extract. The anterior applicators must be made very thin, otherwise there is difficulty in finding room for them.

We believe this method has every advantage over the method of direct application of cocain solutions to the mucous membrane. Certainly there is less absorption of cocain, because of the small area involved. In septum operations, there is no trauma to the septal mucous membrane.

LOCAL ANESTHESIA FOR THE THROAT

For tonsillectomy, we think that cocain has no equal. We use eight c.c. of a 0.2 per cent solution, with twelve drops of 1:1,000 solution of adrenal extract added just before injection. This mixture gives a more certain anesthesia than novocain. Also, there is decidedly less bleeding. The occasional failure of novocain and similar drugs to produce a complete anesthesia in tonsillectomy is injurious to one's reputation.

The addition of the adrenal extract is all-important. The only poor results we have had were when we used adrenal extract not sufficiently fresh. Twelve drops may be more than is usually used, but we believe that this quantity assures freedom from absorption of cocain.

Our method of preparing the solution is as follows: a 4 per cent stock solution of cocain is made and kept about two weeks before use, when it will be sterile from starvation of any organisms that may be present. In order to assure relatively sterile precautions, we make this solution ourselves in the office. It is made up in camphor water to keep out fungus growths. In the operating room this is diluted with sterile salt solution, first to one per cent, then to two-tenths per cent.

Over a period of thirteen years we have had no disturbing, toxic effects from cocain in tonsillectomy.

CONCLUSIONS

1. Local anesthetic is the anesthetic of choice in eye, ear, nose and throat operations.
2. Cocain remains the most important anesthetic.
3. No undesirable results have been observed from cocain combined with adrenal extract when exhibited in proper dosage.

THE ANESTHESIA PROBLEM AS RELATED TO LOCAL ANESTHESIA*

ROBERT EMMETT FARR, M.D., F.A.C.S.
Minneapolis

FOR many years we have been bombarded with that euphonious term "selective anesthesia." The idea of the "selection" of the exact type of anesthesia from among the many excellent methods (individual and combined) that are now available, is so intriguing, that it is small wonder that he who advocates such a routine finds his audience properly attuned and in thorough agreement with his suggestions.

When, however, one visits the various clinics throughout the country and critically observes the methods being followed, he will find as a rule that, except in rare instances, every surgeon or group of surgeons is apt to be "wedded" to *one* or seldom more than *two* types or methods of anesthesia. The fact is that most surgeons use the method which, in their hands, or under their surgical environment, gives them the greatest satisfaction. The term "environment" is used advisedly as it is believed one's surgical environment or his special training are the most frequent causes for choosing any particular type of anesthesia. Those in control of the institutions in which they operate may choose the anesthetic, but the majority of surgeons are under no such control. Thus many surgeons are not exactly free agents. Furthermore, the anesthetic which is the *safest* in one institution is not necessarily so in another.

A certain percentage of institutions are so equipped that many methods may be tested out and compared. Unfortunately, such institutions are in the minority. Likewise, as a rule, surgeons are prone to accentuate the advantages of the particular anesthetic they are using. This is but natural. These considerations must be taken into account when evaluating the merits of the various types of anesthesia, as few surgeons are so fortunate as to be able to test them individually and give unbiased opinions. There may be a "best" anesthetic for every individual case, but the difference in opinion regarding it is apt to be influenced by the above-mentioned factors. Every known anesthetic has both advantages and disadvantages and many of the former are directly due to the excellence of technic of administration.

Probably no anesthetic possesses such outstanding qualities that it should be used quite universally and yet it is probably true that certain individuals or groups may use *one* method to the exclusion of all others with an increased margin of safety.

In choosing an anesthetic, two of the above points must be kept in mind: The surgeon's ability to bring to his patient *safe* general anesthesia, or to use the "local anesthesia method" *safely, skillfully* and *successfully*. To the writer's mind, this amounts to employing "selective anesthesia" in the superlative degree.

Obviously, if a surgeon is not properly equipped to offer to his patients the greatest safety, comfort and efficiency with local anesthesia, some other type should be used. In the final analysis, therefore, it is, as a rule, not the *anesthetic* so much as the *anesthetizer*, that counts in the choice of an anesthetic.

The writer believes that the frequent disagreements regarding local anesthesia have occurred because the spoken term meant one thing in some instances, and in others something else again.

For instance, if one were able to perform a hysterectomy or a cholecystectomy or reduce a fracture† as satisfactorily under local anesthesia as the excision of a small skin tumor, all would agree, perhaps, that "selective anesthesia" would indicate its use for these major procedures. There should, therefore, be no objection to this choice if made by one who *can* accomplish this feat. And yet it is those who *cannot* accomplish this feat who offer the objections to the use of local anesthesia in just such instances. Is it not possible that we have been conversing in different languages? That those who have not mastered

*Read by Dr. W. N. Graves at the annual meeting of the Minnesota State Medical Association, Duluth, Minn., July 16, 1930.

†For over twenty years the writer has reduced more than 98 per cent of his fractures under local anesthesia. Muscular relaxation is one of the outstanding results of this method.

the art of local anesthesia for major surgery, have "selected" some general anesthetic on this account? For those who *can* employ this anesthetic satisfactorily in certain operations, should it not be the one of choice? Is not this often the real point of controversy between those who favor general over local anesthesia and vice versa? Is it not a fact that when one listens to speakers upon this subject, he should consider *who* is doing the speaking and exactly the type of work the speaker is capable of doing? Must it not be admitted that in certain hands *local* anesthesia is the one of choice, while in others—especially those who have access to ideal general anesthesia, and have not mastered the technic of local anesthesia—the "selective anesthesia" of choice should be *general* anesthesia?

When the profession realizes and admits these facts there will be far less controversy concerning the subject of anesthesia. One longs for the day when *all* will use the *same language* when speaking of anesthesia—especially *local* anesthesia.

There are surgeons who: (1) can employ local anesthesia ideally in a vast percentage of all types of cases; (2) can obtain ideal general anesthesia; (3) cannot give local anesthesia well and can only poorly control the administration of general anesthesia.

Obviously, these three classes of surgeons—and they merge into one another—look upon the subject of anesthesia from different viewpoints. Provided what the writer has said is true, their varying viewpoints are easily explained and understood. The most desirable "selective anethesia" is that which, in the hands of the surgeon who performs the operation, gives the patient the greatest protection and comfort—at the same time permitting the best opportunity for meeting the indications. For a particular operation, local anesthesia may be *ideal* in the hands of one surgeon and a *fiasco* with another.

A number of years ago, the writer took part in a symposium before the American Association of Anesthetists. One speaker (an Englishman) asserted that chloroform was the anesthetic of choice and "proved" his point by mentioning the shortcomings of all other anesthetics. We then heard extolled the advantages of ether, nitrous oxid, nitrous oxid and ether, nitrous oxid and local, ethylene, spinal, and finally the writer attempted to explain wherein they were *all* wrong and that *local* anesthesia was usually the method of choice. Paradoxical as it may seem, we may *all* have been right—under certain circumstances, while under others, we *all* may have been wrong. The writer believes that this is the crux of the anesthesia problem today.

A few words regarding local anesthesia may be apropos. There are three distinct methods of applying this anesthetic and the writer believes that local anesthesia has no successful competitor when the all-important question of safety is considered; and when all is said and done, *safety* is the factor which is of the greatest importance. The three methods are as follows:

1. Spinal or intradural.
2. Regional or conductive.
3. Infiltration or infiltration block.

The subject of spinal anesthesia has been ably considered by our guest, Doctor Jackson.

The *regional* is the ideal method of applying local anesthesia, in instances in which it applies. as in intercostal, sacral, trigeminal, brachial and occasionally in the extremities. While ideal when indicated, its field of application is somewhat limited and the failures of novices who attempt to follow the teachings of the experts have done more to retard the use of local anesthesia than have the so-called "extravagant claims" of those who have mastered the technic of local anesthesia.

The third method, *infiltration* anesthesia, has by far the wider field of application and its technic is more simple, more easily taught and acquired and gives a higher percentage of success than does regional. It is the writer's belief that when surgeons master the technic of infiltration anesthesia and the *surgical technic necessary to make it a success,* local anesthesia will be more widely accepted.

Of course we shall always be confronted by that ephemeral specter, "psychic shock." And yet if the entire public were convinced that they were being operated upon in the *safest* possible manner and fully believed this to be the ruth, one wonders how great a part psychic shock would play. It is significant that reports of excellent results following sacral anesthesia combined with suprapubic infiltration with novocain, for the operation of prostatectomy, are now coming from the very clinic that has stressed the dangers of "psychic shock" to the *n*th degree. One wonders why patients with enlarged prostates

are not also victims of psychic shock as well as other classes, yet this factor is ignored in these reports. Aside from exophthalmic goiter, psychic shock should play as great a rôle here as in any type of surgery. The same is true in hernia.

The writer, after operating upon several thousand conscious patients, must confess his inability to recognize this entity—provided the patients were properly handled before, during and after operation and were not compelled to suffer *pain.*

As a good example, we might even take the bad case of exophthalmic goiter. Why is it that these patients often lie quietly during the induction of local anesthesia (provided this is made painlessly) and the early steps of the operation, only to "go to pieces" or show what the writer presumes is "psychic shock" when the gland is mobilized and the "deep" portion of the operation is being carried out?

The writer believes that it is due to failure to obtain *complete anesthesia* of the *deeper structures.* He has consistently operated upon these patients, sending them back to bed with a slower pulse, and apparently in better condition, than before operation—except when he failed to obtain complete anesthesia, or was guilty of committing some other surgical or psychic insult to the patient. Pain, unnecessary noise, traction, choking, pressure, an uncomfortable position, or some other type of insult have been the usual reasons for trouble in all types of cases.

In conclusion, the writer wishes to stress the following points:

The patient is entitled to the anesthetic that gives the acme of *safety, comfort* and *efficiency* of operation.

"Selective anesthesia" is frequently a misused term.

The surgeon's particular *environment* is closely associated with the choice of an anesthetic, and this is a far more important criterion than the particular type of anesthetic employed.

It is not nearly so important to select the drug as to know *by whom* it is to be administered—*and how!*

Local anesthesia, properly administered and accompanied by the necessary *finesse* in surgical technic, is the *safest* anesthesia yet discovered.

Patients' fear is, to a large extent founded upon reports of the improper use of local anesthesia.

So-called "psychic shock" as a result of operating under local anesthesia is, as a rule, a manifestation of *pain* or *errors in local or surgical technic, or management of the patient.*

In the writer's experience, thousands of completely conscious patients of all ages have not shown this complex, when handled ideally and properly managed and operated upon *without pain.*

Infiltration anesthesia (except when regional is indicated) is the local method of choice and if properly injected and reinforced by special surgical technic and ideal psychic management will, in trained hands, permit the ideal performance of a wide range of operations.

Under the requisite environment, "selective anesthesia" will point to local anesthesia as the method of choice in a vast percentage of operations, both minor and major.

When choosing any anesthetic we should "select" its *best* fruits—not its *abused technic*—as our *standard.*

In choosing an anesthetic, the *drug* is secondary in importance to the *anesthetizer,* and when using local anesthesia, the *type of surgical* technic may be, and frequently is, more important in insuring a successful issue than the local anesthesia technic.

LOCAL ANESTHESIA*

Stanley R. Maxeiner, M.D., F.R.C.S.
Minneapolis

THE past ten years has seen a very great tendency towards other methods than general inhalation anesthesia. The use of intravenous and spinal anesthesia has increased rapidly in popularity. However, the writer feels that there is no contest between the various methods of producing anesthesia but that the choice should rest with the judgment of the operator as to the type of anesthesia to be employed in any given case. In the healthy, robust individual, almost any anesthetic will suffice; but in the seriously ill, profoundly toxic, or substandard risk, local anesthesia is undoubtedly still the safest procedure. We believe that the profession as a whole prefers to avoid general anesthesia if possible, and even the most ardent advocates of spinal anesthesia warn against its use in the profoundly toxic patient.

In the recent advances in the surgical treatment of acute nephritis, local anesthesia plays an important part. Here again we are dealing with the critically ill patient and the anesthetic is of vital importance. For more than sixteen years we have used some type of local or regional anesthesia in the treatment of fractures. We have repeatedly used the brachial anesthesia for arm and forearm fractures, and infiltration directly into the site of fracture when this type of anesthesia is indicated.

We personally watched Babcock perform, under local anesthesia, a colostomy on a long standing intestinal obstruction with severe toxemia and fecal vomiting, and operate upon another patient with a ruptured appendix, peritonitis and a secondary abscess, causing an intense toxemia.

Matas states that as a rule he never resorts to spinal anesthesia in weak, exhausted and hypotensive subjects. We would quote Labat as follows:

"The wholesale use of spinal anesthesia should be discouraged and its application throttled down to surgical necessities. Its simplicity of technic and clinical advantages over all the other methods of anesthesia have served in the past to stimulate its routine administration by the inexperienced. It was given to all classes of patients for all types of operations."

Although Koster states that he has not had a fatality attributable directly to spinal anesthesia, nevertheless he reports four fatalities as possibly having been contributed to by spinal block. One was an old man with obstruction, the second a diabetic with spreading gangrene, the third a child of six with obstruction from Meckel's diverticulum, and the fourth a suppurative peritonitis with myocarditis. If we are to judge by the teaching of many, these are the cases not suitable for spinal anesthesia.

The writer has repeatedly used other forms of anesthesia and believes firmly that one must not be wedded to one type of anesthesia to the exclusion of all others. In other words, we agree explicitly with Matas when he states that in the matter of anesthesia one should be selective and eclectic and not a routinarian.

After all, is it not true that one of the greatest factors leading to the success of local anesthesia is that the surgeon cannot traumatize tissue with impunity? He cannot, for instance, pull upon the abdominal viscera and maintain a negative intra-abdominal pressure. By demanding far greater respect for the tissues and a much more painstaking and refined technic, local anesthesia helps to prevent shock and affords a less stormy convalescence. We have used local anesthesia alone; with morphine and scopolamine, hypodermically (Farr's narcolocal anesthesia); likewise with gas to produce the anoci-association of Crile; and we have also repeatedly used it in conjunction with spinal anesthesia. We have seen surgeons operating with an incomplete spinal anesthesia, the lower abdomen, for instance, being completely anesthetized, but the anesthesia in the upper abdomen being incomplete, requiring the additional administration of gas or ether. We have likewise seen and experienced the waning of perfect spinal anesthesia due to a prolonged surgical operation in which general anesthesia had to be added. We have

*Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minn., July 16, 1930.

found, however, that the addition of splanchnic block to the stomach or gallbladder and an infiltration of the sensitive portions of the abdominal incision have permitted us to complete a much drawn out surgical operation in which the spinal anesthesia waned or was incomplete. We would strongly recommend the use of local and splanchnic anesthesia under such circumstances.

Novocain has been so efficient, so free from danger, and of such minimum cost, that it has been almost universally accepted for local anesthesia. Many newer drugs have arisen, but until it is proven that their advantages supersede those of novocain they should not be substituted. Solutions of 1 per cent for infiltration anesthesia and 2 per cent for nerve blocking have, in our hands, proven most efficient. Solutions should be prepared in large quantities from accurately weighed novocain crystals, rather than from the tablets, which are more expensive and less likely to be sterile. Adrenalin, in quantities from two to three minims per ounce, prolongs the anesthesia, reduces absorption and likewise toxicity. This addition is best avoided in cases of hyperthyroidism.

Regional anesthesia and nerve blocking are far more difficult and in most instances possess no advantages over straight infiltration and infiltration block anesthesia. Because of its greater simplicity, the ease of its induction and the fact that it carries a much higher percentage of success, infiltration anesthesia, when indicated or combined with blocking, is much more practical in the hands of the general practitioner and the general surgeon. We believe that it is extremely important that the anesthetic solution be injected by the operator and there are now scattered throughout the country many excellent surgeons in small clinics, where the general anesthetist is not so well trained, who are doing the greater portion of their major surgery under local anesthesia.

It is needless to say that proper equipment is paramount; good syringes with fine needles cannot be displaced by leaky syringes with poorly fitting, dull aspirating needles. One must constantly bear in mind that the patient who is awake may soon become uncomfortable and object more to his position upon the table or the binding straps upon the arms than to the operation itself, and his comfort is an important consideration.

General Technic.—The technic of local anesthesia and local anesthesia combined with infiltration block is so simple that it can be used by any surgeon who is willing to master its details. If the injecting needle is always kept in motion and the solution projected ahead of the needle, the advance of the needle will be painless and safe. If, however, the needle is plunged into the tissues without the solution being projected ahead of it and a large injection made with the point of the needle stationary, the procedure will be painful and may be dangerous if the point of the needle should penetrate a vein. It has been advanced that this explains the fatalities from local anesthesia in throat operations, where a very fine needle may easily be plunged into the venous plexus behind the tonsil and an intravenous dose administered.

Technic of Injection.—A very fine needle is used to make the primary wheal at the edge of the operative field. From this wheal, secondary wheals are made by bringing a longer needle into the skin from below. In this manner all secondary wheals are made painlessly. The patient should feel in the skin only the first needle prick and not a succession of wheals, as illustrated in a recent textbook on umbilical hernia, which only causes loss of confidence in method. When it comes to anesthetizing the abdominal wall through the primary and secondary wheals the underlying layers have been thoroughly infiltrated. Similar infiltration of the line of incision together with the blocking of the ilioinguinal and iliohypogastric nerves and a subsequent block of the genital branch of the genito-femoral, when the cord is uncovered, is adequate for the repair of any inguinal hernia. The same method applies to work upon the extremities when, for instance, the leg is circumscribed and an infiltration block is made of the nerve trunks, rendering everything distal to the point of injection completely anesthetized. By this procedure we have been able to treat fractures by the open or closed method, to perform amputations, etc. The same infiltration whether circumscribing the thyroid gland or, as we now usually do, infiltrate radially from a central puncture in all directions, combined with a blocking of the upper cervical nerves on both sides, will permit a painless removal of even the most difficult substernal thyroid. It is a wonderful comfort to the surgeon to have a patient talk during a thyroidectomy and

know the recurrent laryngeal nerves have not been injured. In the scalp or in the thorax, infiltration and infiltration blocking permit painless trephining or thoracoplasty. Infiltration along the line of incision and blocking of the lower four thoracics will permit delivery of the kidney and exposure of the pedicle, which itself may be readily infiltrated after it has been exposed. Nephrotomy by this technic is comparatively simple; nephrectomy is more difficult.

By the use of the infiltration technic as described, the abdomen may be opened with an entirely negative intra-abdominal pressure and without any expulsion of the abdominal contents. At this point, one must be resourceful in the examination of the various viscera through inspection rather than by palpation. With forceps or retractors, the abdominal wall is lifted, permitting the division of adhesions and the visualization of the gallbladder through a lower abdominal incision. In the Trendelenburg position, with vertical retraction, the pelvic organs may be visualized without the use of gauze packs. No attempt should be made to perform any intra-abdominal operation beyond this point without the addition of splanchnic anesthesia. This is probably the greatest step in the advancement of this method within the abdomen. With the colon and the omentum lifted upward, one may block the greater portion of the splanchnic nerves at the base of the transverse mesocolon, or segments of bowel only may be anesthetized. The appendix or the entire cecum and terminal ileum may be blocked or by following the posterior peritoneum at the brim of the pelvis, all of the splanchnics may be intercepted as they descend to the pelvic organs. When the uterus is free a local splanchnic blocking of both the broad and round ligaments and the peritoneum about the cervix will permit a painless hysterectomy. Likewise a local splanchnic blocking about the gall bladder and the peritoneum over the ducts will permit all types of operation in this location. We have removed the entire stomach, resected large portions of the colon, removed the gallbladder and performed the abdomino-perineal Coffey operation for cancer of the rectum by this method with entire satisfaction, even in some patients who were markedly substandard risks.

In conclusion, let me again state that we do not advocate the sole use of any type of anesthesia, but we firmly believe that local anesthesia has a definite field in all types of surgery and particularly in the substandard risk. We would also strongly recommend local anesthesia as an adjunct to incomplete or waning spinal anesthesia.

PULMONARY COMPLICATIONS OF GENERAL ANESTHESIA*

Ralph T. Knight, B.A., M.D.
Minneapolis

I HAVE been asked to discuss general anesthesia with particular reference to its complications and have chosen to omit the gastro-intestinal, renal and general chemical complications such as acidosis and to consider for the purposes of this paper only pulmonary complications.

Just a few words about the explosion hazard. This is really a pulmonary complication, as death occurs from explosion within the lungs. With the use of the modern gases and apparatus there have occurred several disastrous or fatal explosions. Although ethylene is a most excellent anesthetic it has been discarded in many localities on account of its reputation, and yet in one or two places where accidents have occurred this gas is still used.

In the Journal of the American Medical Association of March 29, 1930, the Council on Physical Therapy of the A. M. A. published the report of its Committee on Combustible Anesthetics written by H. B. Williams of the Department of Physiology of Columbia University. He carefully reviewed the physical causes of explosions and outlined the precautions necessary to avoid ignition, some of which are practically impossible of general attainment but most of which can be incorporated in a well made apparatus or routinely practiced in well ordered operating rooms. His closing paragraph is as follows:

"Finally, I would state that it is my considered opinion after careful investigation that there is a real and serious hazard in the use of ethylene or ether in modern anesthesia apparatus in which combustible gas or vapor is mixed with oxygen or nitrous oxide and contained in or passed through rubber rebreathing bags or rubber tubing. This hazard is greatly increased by the practice of washing out the apparatus and the patient at the end of the procedure with oxygen-rich mixtures." The whole report is helpfully warning but discouraging.

Rather in contrast to it is the later report published in the A. M. A. Journal of May 10, 1930, by the general A. M. A. Committee on Anesthesia Accidents. This report was drafted by the Chairman, Yandell Henderson of Yale. The committee included Lundy of Rochester, Minnesota, Scott of Rochester, New York, Wells of Chicago, and H. B. Williams of New York, who wrote the former report. This report of course also outlines all the dangers and necessary precautions, but after a survey of upwards of 200,000 ethylene anesthesias, they reach the conclusion that statistically there have not been more than about one explosion death per hundred thousand cases, which is negligible compared with other hazards of anesthesia, and with the advantages of ethylene over all other inhalation anesthetics. I myself feel that all suggested precautions should be met, with the exception of the prohibitory one of the grounded metal strips in the floor, and that ethylene is too valuable to be discarded until a more perfect gas is found.

Pulmonary complications stand out as one of the most important considerations in choosing an anesthetic and are still the paramount cause of post-operative morbidity and mortality.

Graham's recent work, "Surgical Diagnosis," gives figures for pulmonary complications in various clinics that differ rather widely, from .7 per cent in Pittsburgh to 4 per cent in Moscow. A part of this difference may be due to the omission in some series of minor coughs, etc., and complications which arose almost too late to be considered as possibly due to the anesthetic.

We have hurriedly reviewed 1,015 surgical cases at the University Hospitals. This is an unselected group except that nose and throat operations were not included. This is not a large enough series from which to draw very definite conclusions but certain impressions at least can be derived. All these cases were prior to the last four months during which time all patients have been hyperventilated after operation daily for six days.

Table 1 shows 30 pulmonary complications in the 1,015 cases. One patient developed bronchopneumonia on the fourteenth day after operation

*From the Department of Surgery, University of Minnesota. Read before the annual meeting of the Minnesota State Medical Association, Duluth, Minn., July 16, 1930.

and recovered. In another patient who recovered, atelectasis occurred on the eleventh day. One patient died on the tenth day, having gastric retention and vomiting as well as bronchopneumonia; one on the fourth day following a perforated appendix having general peritonitis and septicemia as well as bronchopneumonia; one on the twenty-second day after an acute mastoid operation with general septicemia as well as bronchopneumonia; and one died on the twelfth day of bronchopneumonia which did not, according to the records, develop until the ninth or tenth day. One could without much twinge of conscience omit these six cases including four deaths from the list of complications due to the anesthetic. I did have the temerity to exclude one bronchopneumonia death which occurred six weeks after a gastric resection under spinocaine.

TABLE I
ANESTHETICS

		Pulmonary Complications	Deaths
8	Novocaine	0	0
39	Novocaine, Nitrous Oxide	0	0
64	Novocaine, Ethylene	0	0
2	Novocaine, Ethylene, Ether	0	0
58	Spinocaine	0	0
6	Spinocaine, Nitrous Oxide	1	0
7	Spinocaine, Ethylene	0	0
6	Spinocaine, Ethylene, Ether	2	1
120	Nitrous Oxide	2	1
46	Nitrous Oxide, Ether	3	1
205	Ethylene	3	0
117	Ethylene, Ether	4	1
14	Ether, Colonic	0	0
15	Ether, Colonic and Inhalant	1	0
305	Ether, Inhalation	13	4
4	Chloroform	1	1
1015	Total	30	9

Of these four fatal cases, two received ether, one nitrous oxide-ether, and one ethylene-ether. The eleventh day atelectasis and the fourteenth day bronchopneumonia received ether. These will not be referred to again, but please remember charitably in looking at the following tables that these six cases might rightfully be omitted, reducing the nitrous oxide-ether and ethylene-ether pulmonary complications to two and three without a fatality; the ether to nine, with two fatalities; and the total to twenty-four, with five fatalities. In addition to the above, the one death after chloroform was due to bronchopneumonia following resection of the mandible. This seems more probably an operative rather than an anesthesia sequela.

The thing most noticeable in this table is the increase of the figures on the ether lines.

I have made cross reference tables for each anesthetic and for each body region operated upon but have largely consolidated them for this presentation. It will be noted that some of the types of anesthesia had no pulmonary morbidity. These were novocaine and spinocaine alone and with certain additions, 192 operations having been done on various regions under these anesthetics without pulmonary complication. The use of ether seems, according to this table, to increase the incidence of pulmonary complications.

TABLE II
OPERATIONS OUTSIDE OF ABDOMEN, UNCOMPLICATED

		Pulmonary Complications	Deaths
10	Head	0	0
2	Eye	0	0
17	Lip, Palate	0	0
34	Upper Extremity	0	0
28	Kidney, Ureter	0	0
53	Inguinal, Male Genitals	0	0
10	Rectum	0	0
48	Lower Extremity	0	0
6	Spine	0	0
17	Skin	0	0
225	Total	0	0

Now turning to the table on anatomical regions operated upon (Table 2), we see that there are a goodly number of regions where operations show no pulmonary morbidity, regardless of the anesthetic used. Upon these regions (the head, eye, lip and palate, upper extremity, kidney and ureter, inguinal region, male genitals, rectum, lower extremity, spine and skin), 225 operations were performed with various anesthetics without pulmonary morbidity. On the other hand, other regions (Table 3) bear the brunt of the pulmonary trouble. Three hundred ninety-five operations were performed on regions other than the abdomen with three deaths among nine pulmonary complications, while 395 other operations were performed within the abdomen, with six deaths among twenty-two pulmonary complications.

TABLE III
OPERATIONS OUTSIDE OF ABDOMEN, COMPLICATED

		Pulmonary Complications	Deaths
6	Ear, Mastoid	1	1
15	Bony Oral	3	1
156	Neck	2	0
43	Chest	1	1
29	Bladder	1	0
146	Cervix, Vagina, Perineum	1	0

OPERATIONS, ABDOMINAL

		Pulmonary Complications	Deaths
141	Upper Abdomen	15	4
254	Lower Abdomen, Pelvis	6	2
395	Total Abdominal	21	6
1015	Grand Total	30	9

It would seem then that work within the abdomen, and especially the upper abdomen, incurs a greater risk of pulmonary complications than that in other regions.

Each anesthetic was tabulated according to body regions, and each region according to anesthetics used.

TABLE IV

		Pulmonary Complications	Deaths
EAR, MASTOID			
2	Ether Alone	1	1
3	Ether Reinforcement	0	0
1	Without Ether	0	0
6	Total	1	1

15	Total	2	1
NECK			
7	Ether Alone	0	0
12	Ether Reinforcement	1	0
137	Without Ether	1	0
156	Total	2	0

Table 4 shows the ear, mastoid, bony oral surgery and the neck. All but one of the five complications and both of the deaths followed ether anesthesia. Neck operations were practically free from pulmonary complications, one case of bronchitis following one of the twelve ether reinforced anesthesias, and one bronchitis following one of the 136 without ether.

TABLE V

		Pulmonary Complications	Deaths
BLADDER			
2	Ether Reinforcement	0	0
27	Without Ether	1	0
29	Total	1	0
CERVIX, VAGINA, PERINEUM			
2	Ether Alone	0	0
15	Ether Reinforcement	0	0
129	Without Ether	1	0
146	Total	1	0

Table 5 shows the operations on bladder, cervix, vagina and perineum, in which no trouble followed the administration of ether. It was given in nineteen of the 175 cases. In operations in this region there were only two pulmonary complications, and these without fatality—a pretty safe region to operate upon, pulmonarily speaking.

Table 6 shows operations upon the chest, upper abdomen and lower abdomen and again shows a much higher incidence in abdominal operations, especially in the upper abdomen, with an additional increase when ether was used. Strangely enough (a thought which had not occurred to me before), the morbidity and the mortality seem to be greatest when ether was used as a reinforcement to some other anesthetic rather than when it was used alone. Following abdominal operation hyperventilation with carbon dioxide on the days following operation produces quite severe pain in the operative field, indicating the reason for shallow respiration following this type of operation.

TABLE VI

		Pulmonary Complications	Deaths

34	Outside of Abdomen	0	0
117	Total	3	1

Table 10 is the story of ether compared with other anesthetics. When ether was used alone, upper abdominal operations were followed by almost five times as many pulmonary complications as lower abdominal and extra-abdominal operations. When ether was used as a reinforcement to other anesthetics, upper abdominal operations showed seven times as many complications as lower abdominal, and ten times as many as extra-abdominal operations. Other anesthetics used in upper abdominal cases gave only twice as many as in lower abdominal cases, and four times as many as for those outside the abdomen.

Comparing different anesthetics for the same regions:

Upper Abdomen.—Ether reinforcement resulted in over twice as many pulmonary complications as ether alone, and five times as many as other anesthetics.

Lower Abdomen.—Ether reinforcement was followed by twice as many complications as ether alone, and over 50 per cent more than other anesthetics. Ether alone was accompanied by even fewer complications than other anesthetics.

Extra-abdominal.—Ether reinforcement showed more complications than ether alone, and the latter twice as many as other anesthetics.

The thirty cases with pulmonary complications are shown in more detail in Table 11. These included 1 case of pleurisy with effusion, 2 of atelectasis, 9 of bronchitis, 4 of lobar pneumonia with 1 death, and 15 of bronchopneumonia with 8 deaths. Ages ranged from 7 to 72; in the fatal cases from 12 to 69, the average for both being 48. Eighteen of the 30 patients were over 50; 12 over 60. Six of the 9 fatalities were over 50; 4 over 60. The duration of the anesthesia in the 30 cases was from 25 to 185 minutes; in the 9 fatal cases from 40 to 125 minutes. The average in both was 80 minutes.

TABLE XI

PULMONARY

	Complications	Deaths
Pleurisy	1	0
Atelectasis	2	0
Bronchitis	9	0
Lobar Pneumonia	4	1
Broncho-Pneumonia	14	8
Total	30	9

AGES: 7 to 72; average, 48. 18 over 50; 12 over 60.
FATAL CASES: 13 to 69; average, 48. 13, 17, 29, 56, 59, 62, 62, 67, 69.
ANESTHESIA: 25 to 185 min., average 80.
FATAL CASES: 40 to 125 min., average 80.

Conclusions: A review was made of 1,015 anesthesias administered at the University hospitals. Pulmonary complications followed in 30 cases (3 per cent), with 9 deaths (0.9 per cent).

Six of the complications, including 4 deaths,

might easily be considered either as occurring too late to be related to the anesthesia or as being a part of a general septicemia, related to the surgical condition rather than to the anesthesia.

Ether administered alone caused about twice as many pulmonary complications as other anesthetics.

Ether used as reinforcement to other anesthetics caused five times the pulmonary complications in upper abdominal operations, twice as many in other types of operations.

Upper abdominal operations, as compared with extra-abdominal work, were followed by pulmonary complications ten times as frequently with ether reinforcement, five times as frequently with ether alone, and four times as often with other anesthetics. This indicates that ether is a potent factor in pulmonary complications, but that the upper abdomen as an operative field is a still more important consideration.

Ethylene causes less pulmonary irritation than any other inhalation anesthetic, and this feature is in fact almost negligible.

1543 Medical Arts Bldg.

SOME CLINICAL FEATURES OF OBSTRUCTIVE JAUNDICE*

ALBERT M. SNELL, M.D., and FERDINAND M. JORDAN, M.D.
Rochester, Minnesota

ANY physician who has studied the symptoms of many patients with jaundice will agree that the diagnosis is difficult if only because the clinical pictures encountered in actual practice do not often resemble the classical ones described in the textbooks. Much information is needed as to the frequency with which variations in the classical picture can be expected to occur; the atypical cases also deserve particular study. In an effort to clarify, in our own minds, the problem of differential diagnosis in cases of jaundice, we have analyzed the records of 130 cases of obstructive jaundice which have been carefully studied during hospitalization at The Mayo Clinic.

THE CLASSIFICATION OF JAUNDICE

Since Mann and his associates have proved conclusively that bile pigment is formed outside of the liver and is brought to it for excretion, we have learned to classify clinical cases of jaundice into three groups (McNee): (1) obstructive jaundice, including cases in which there is occlusion of or obstruction in the extrahepatic biliary passages; (2) intrahepatic jaundice, comprising cases in which the lesion lies in the hepatic parenchyma, either in the finer bile passages or in the cells of the liver itself, and (3) hemolytic jaundice, associated with increased destruction of blood cells and subsequent increase in the level of bile pigments in the blood (Fig. 1). Each of these groups presents a different therapeutic problem, and consequently a quick method of classification of any given case of jaundice is highly desirable. The points essential to a working classification, according to McVicar and Fitts, are as follows: "(1) The reaction of the jaundiced serum to the van den Bergh reagent (whether direct or indirect); (2) the height and behavior of the serum-pigment curve as determined by the van den Bergh test or by the icterus-index method; (3) the quantity of bile reaching the intestines as determined by siphonage of the duodenal contents, and (4) the presence or absence of pain, and its character when present."

With these data on hand, one usually can arrive at a working diagnosis in most cases of jaundice. If an anatomic diagnosis cannot be made positively, at least the obscure cases can be divided into surgical and nonsurgical groups. The significance of such prompt classification is obvious, when one recalls the injury which obstructive jaundice causes to the biliary passages and the hepatic parenchyma.

In attempting to diagnose the cause of jaundice, one should recall the percentage distribution and frequency of the various types as they are encountered in practice. In 450 cases of jaundice at The Mayo Clinic, Hartman found that in approximately 23 per cent the lesion was intrahepatic, in about 7 per cent the disease was of the hemolytic type, and in the remaining 70 per cent obstructive lesions of the hepatic or common bile ducts were present. Carcinoma accounted for about 25 per cent of the cases; of these, malignancy of the pancreas was the most common single cause, and tumors of the gallbladder and bile ducts taken together were about half as common. Metastatic lesions and general carcinomatosis accounted for a total of about 7 per cent of all cases of jaundice. Of the benign lesions, stones in the common bile duct were responsible for 20 per cent and stricture of the common or hepatic ducts for 10 per cent. From the foregoing, it is apparent that the three conditions which should be thought of first in attempting a differential diagnosis in a case of jaundice are intrahepatic jaundice, carcinoma, and stone in the common bile duct.

STONE IN THE COMMON BILE DUCT

Our series of patients with stone in the common bile duct comprised seventy-one. In this group the usual predominance in females was noted (a ratio of about three females to two males). The average age of the patients was fifty-five years, and the average duration of

*From the Division of Medicine, The Mayo Clinic, Rochester, Minn. Read before the Minnesota State Medical Association, Duluth, Minn., July 14 to 16, 1930.

symptoms, six years. About a third of the group had had previous surgical operations on the biliary tract.

The essential characteristics of jaundice due to stone in the common bile duct are that it is intermittent, painful, rarely complete, and that

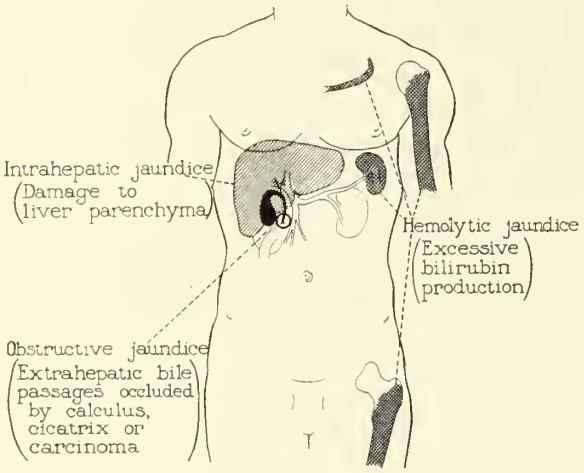

Fig. 1. Various types of jaundice.

the associated symptoms are usually of long duration.

Analysis of the symptom of pain in this group of cases brings out a number of interesting points. Forty-nine of the patients had had typical biliary colic; seven had had violent seizures of epigastric pain; one patient had had definite colic situated in the left upper quadrant of the abdomen, and another patient had had only lumbar pain. Diffuse abdominal pain, without accurate localization, was noted in seven cases. In six cases the jaundice was painless or practically so. From the foregoing, it appears that in nearly 30 per cent of cases of stone in the common bile duct, the pain is atypical in its localization or nature, or so mild that it is only a minor feature in the case. In all but six cases, however, the character of the attacks was such as to suggest either actual colic or its equivalent. The relation of these painful seizures to the appearance of jaundice is significant. In fifty-five of the seventy-one cases, jaundice followed immediately after the attack of pain. In ten cases, the jaundice came on shortly after what might be termed the equivalent of colic. In the remaining six cases, there had been too little pain to connect it accurately with the history of the onset of jaundice, although in all of these cases, general malaise, chills, nausea and vomiting, and other minor symptoms were associated with the first appearance of the jaundice. In a large majority of cases, painful attacks, of whatever type, were followed by residual soreness, nausea, and vomiting. Chills and fever were noted in about half of the cases, and pruritus in more than half; usually these symptoms were at their height shortly after an attack of pain. These associated phenomena are often helpful in identifying the cause of atypical colic. About half of these patients had had attacks of pain and jaundice prior to the attack which brought them to the clinic for relief, and frequently inquiry into the nature of these earlier and half-forgotten attacks afforded us most valuable information.

There are two features about the clinical picture of stone in the common bile duct which have not received much attention. The first feature is the tendency of the attacks to increase in frequency and severity; this is a striking point in many histories. The second feature is indigestion, which often antedated by years the attacks of pain. In all but four in this group of seventy-one cases, there was a long history of intolerance to food, postprandial distress, flatulence, and so forth. Just as a patient with pyloric obstruction frequently will forget to mention the original symptoms of ulcer, so do these persons with jaundice due to stone in the common bile duct forget to mention the old symptoms of indigestion and abdominal distress which characterized the onset of their illness.

The importance of determining the patency of the biliary passages in obstructive jaundice has been emphasized by Crohn. This information may be obtained by duodenal siphonage or by examination of the stools; the patient's statements alone rarely can be relied on to decide this question. In our cases of stone in the common bile duct, bile was present in the material obtained by duodenal drainage in 80 per cent of the cases in which intubation was performed, and examination of the stools furnished confirmatory evidence in many cases. In only ten cases of the whole group was there evidence of complete biliary obstruction, and in these it is not certain that a longer period of observation and more frequent duodenal drainage would not have revealed at least a trace of bile. Our impression is that it is not common for a stone completely to occlude the biliary passage for any length of time. In many cases drainage of bile has been absent on

the earlier tests, but after a few days bile appeared in the stools or on duodenal siphonage.

The incomplete and intermittent nature of the biliary obstruction is reflected in the curve of serum bilirubin. In about 70 per cent of the cases the values for serum bilirubin do not at any time exceed 15 mg. for each 100 c.c. In about a third of the cases it was not more than 5 mg. at any time. This is in notable contrast to the levels of serum bilirubin encountered in obstructive jaundice due to carcinoma. Frequently a sharp rise in the serum bilirubin after a painful attack will serve to establish the fact that a stone is present. Other laboratory data do not give very helpful information. Cholecystography with the use of dye is of little value in the presence of jaundice; roentgenograms of the region of the gallbladder occasionally may reveal a stone. Severe anemia is uncommon, although in about 40 per cent of our cases there was some reduction in the concentration of hemoglobin and in the erythrocytes; leukocytosis may be present during the acute attack, but usually it subsides speedily. The coagulation time was within normal limits in all but eight cases; in these it was definitely prolonged, but usually was less than twenty minutes. There was no definite correlation between the coagulation time and the severity of the jaundice, and occasionally we have noted a hemorrhagic tendency in cases in which the coagulation time was within normal limits.

Numerous variations from the typical picture are encountered; in fact, about a third of all cases of choledocholithiasis may be atypical in one or more respects. Jaundice may be absent following colic in some cases; Jordan and Weir are reporting a group of proved cases of this type. Cases of recurrent stone also give difficulty; five patients in this group gave a history of choledocholithotomy done elsewhere, with subsequent reformation of stones. The cases which give the most trouble in diagnosis are those in which patients are older, the history is short and pain is atypical. To establish a positive diagnosis in this group, one must often resort to exploration. Fortunately these cases are rare, but some of them have so many of the characteristics of neoplastic obstruction of the duct that they present difficulty in diagnosis.

The relative frequency of the symptoms and signs of stone in the common bile duct are shown in Table 1. The complications which may accompany obstruction of the common bile duct by stone are of interest because of their bearing on the clinical picture and their effect on surgical risk. In this group, perforated or ruptured gallbladder occurred in four cases; fistulous connections with the duodenum or colon were present in three cases, and an external fistula was noted in two cases. Biliary cirrhosis was often found at operation or at necropsy. Inflammatory conditions of the bile ducts were less common. In two cases subdiaphragmatic abscess followed operation. Chronic pancreatitis was present in nine cases, and hemorrhagic pancreatitis in two. In jaundice due to stone, considerable hemorrhage is not as common as one might expect. In only one case was it the apparent cause of death. In fifteen of this group of cases renal insufficiency occurred as a complication either before or after operation. As a rule, it was only moderately severe and could be controlled by intravenous administration of fluids.

TABLE I

JAUNDICE DUE TO CHOLEDOCHOLITHIASIS (71 CASES)*

Relevant symptoms. signs and history	*Incidence per cent*
Previous indigestion	94
Previous operations on biliary passages	33
Previous attacks with jaundice	44
Typical colic	70

Serum bilirubin 10 to 20 mg. in each 100 c.c.	27
Serum bilirubin more than 20 mg. in each 100 c.c.	7
Biliary passages patent	86
Biliary passages occluded	14
Chills and fever	52
Pruritus	60
Prolonged coagulation time	11

*Ratio of males to females 2:3.

STRICTURE OF THE COMMON BILE DUCT

Stricture was the cause of the jaundice in twenty of the cases in our series. A brief statement of the current hypothesis concerning the etiology of stricture seems desirable. Its primary cause is not definitely known. Whatever the cause, there appears to be little doubt that in predisposed subjects, cholecystectomy is the most significant factor in the development of this condition. In the records of The Mayo Clinic, there

has been only one case in which stricture of the common bile duct occurred without previous operation on the biliary tract and in that case stricture was due to congenital torsion of the gallbladder and ducts. There appear to be two types of stricture: those which are essentially

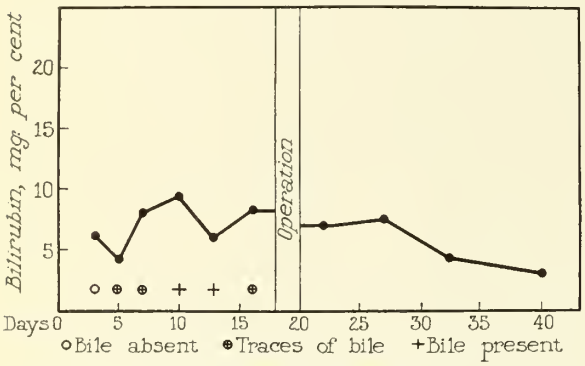

Fig. 2. Curve of serum bilirubin. Results of duodenal drainage in a case of stricture of the common bile duct are shown.

due to surgical trauma, and in which the symptoms develop immediately after operation, and those in which it is probable that direct trauma has not occurred, the stricture developing months after the primary operation. Judd has stated that in a fairly large percentage of cases the condition results from obliterative cholangitis, which is at least partially independent of surgical trauma. He has reported two cases in which jaundice developed four and thirteen years, respectively, after operations on the biliary tract. It is difficult to explain such cases on the basis of operative trauma alone. It seems probable that in many cases of disease of the biliary tract, widespread inflammatory conditions exist in the gallbladder, liver, and biliary passages. In certain cases this inflammatory condition persists after cholecystectomy and produces obliterative fibrosis of the ducts. On this basis one can explain some of the phenomena noted clinically in this group of cases.

The average age of the patients with stricture of the common bile duct in our series was about forty-two years. Eighteen of the twenty patients were females, a point which emphasizes the relatively greater frequency of benign lesions of the biliary tract in women. The total duration of symptoms in this group ranged from six months to thirty years; the average duration was approximately ten years. Since previous surgical operation on the biliary tract was a factor in every case, it is advisable to consider separately the symptoms which occurred before operation. In seven of the twenty cases there was definite biliary colic, and in three there were other and milder symptoms of cholecystitis. For those symptoms cholecystectomy had been performed in nineteen cases and cholecystostomy in one case. None of the patients had been relieved permanently, although one or two of them had had relatively long periods of comfort after the primary operation.

The postoperative symptoms vary somewhat, apparently depending on the degree of cholangitis present and on the presence or absence of surgical trauma. In about a third of the cases jaundice developed immediately after operation, in eleven it developed in from two to eighteen months, and in one case jaundice appeared for the first time two years after the original operation. In another case jaundice developed after an external biliary fistula had been closed. Prolonged postoperative biliary drainage is common in such cases, although it varies greatly in time of appearance, duration, and amount. In general, it bears an inverse relationship to the degree of jaundice present.

After the primary operation, colic was usually somewhat less severe than before. The attacks of pain were often accompanied by chills, pruritus, fever and other signs of biliary obstruction and infection. Indigestion and signs of nutritional disturbance usually increased progressively after the primary operation. In practically all cases there was more or less constant aching or soreness in the upper part of the abdomen.

Obstruction of the biliary tract was complete in six of this group of cases, and of these the obstruction could almost invariably be attributed to direct surgical trauma. In the remaining cases the biliary passages remained partially patent, and small amounts of bile could be obtained by duodenal drainage.

The degree of jaundice, as shown by examination of the serum bilirubin, usually was not great. In eighteen of the cases, the concentration of serum bilirubin was less than 15 mg. in each 100 c.c. Early in the course of the disease the serum bilirubin may fluctuate considerably. A typical curve is shown in Figure 2. The longer the illness the more constant the jaundice seems to be, a fact which may be referred to the biliary cirrhosis and cholangitis, which are almost invariable accompaniments of stricture. In fact

in cases of multiple operations for the relief of stricture of the common bile duct, the end-result is almost identical with the clinical picture of advanced primary biliary cirrhosis. In many cases of stricture there is a large element of intrahepatic jaundice, and the longer the case has progressed, the more likely one is to encounter hepatic insufficiency due to long-standing infection and obstruction of the biliary passages. This explains, at least to some degree, the difficulties of treatment in such cases. In fact, the clinical course of benign stricture of the common bile duct owes a good many of its characteristic features not so much to biliary obstruction as to injury to the parenchyma of the liver. Such injury probably accounts for the marked predisposition of these patients to serious hemorrhage. In our series of twenty cases a coagulation time of more than ten minutes was noted in about half of the cases, and in some of these the coagulation time was prolonged to half an hour or longer. Anemia is common (85 per cent of this group), often resulting from hemorrhage. Hepatic insufficiency, secondary to the marked biliary cirrhosis, was not uncommonly observed, particularly as a terminal feature.

It is fairly easy to make a clinical diagnosis of stricture of the common bile duct. Recurrent stones in the common bile duct may present a somewhat similar picture; occasionally stones may form above a stricture and thus may complicate the clinical picture. The difficulty arises not in the diagnosis but in the treatment of these cases. Nineteen of our twenty patients were operated on at the clinic; one patient died of hemorrhage before operation could be performed. Before the patients came to the clinic, eight of them had had one operation for repair of stricture, three had had two such operations, and two had had a fourth attempt made to repair the biliary passages. The difficulty which is encountered in preparing such patients for operation, the great technical difficulty of the operation itself, and the liability to postoperative complications, such as hemorrhage, and hepatic and renal insufficiency, all combine to make stricture of the common bile duct an extremely serious condition. In spite of this, good temporary results were obtained in half of the cases in this group, and in six of the others, cure may be regarded as permanent.

JAUNDICE DUE TO MALIGNANT OBSTRUCTION

The four varieties of carcinomatous obstruction of the common bile duct are: (1) primary tumors involving the head of the pancreas; (2) primary tumors of the gallbladder; (3) primary tumors of the common, hepatic, or cystic ducts, and (4) metastatic lesions involving any of these structures or the lymph nodes adjacent to the ducts. The diagnosis in all of these cases is likely to be difficult, and in many cases one can only hazard a shrewd guess that the obstructing process is of a malignant nature. Metastatic lesions are not common and frequently can be diagnosed on the basis of a primary malignant growth elsewhere in the body. Primary tumors constitute the really difficult diagnostic problem.

Our series includes thirty-nine cases of obstruction due to carcinoma. In twenty-six of these the lesion was carcinoma in the head of the pancreas, in eight the carcinoma was in the ducts, and in five in the gallbladder. In the group of patients with pancreatic carcinoma there were twenty-one males and five females; the average age was about fifty-five years. The total duration of symptoms in the cases of pancreatic carcinoma averaged about twenty-two months, and half of the patients had had symptoms for less than a year. Two patients had rather long histories, but their earlier symptoms may well have been due to lesions other than carcinoma. Practically all of the patients had had vague complaints of disturbance in the upper part of the abdomen, which antedated by some time the appearance of the jaundice. These disturbances took the form of abdominal soreness, flatulence, anorexia, dull boring epigastric pain and even atypical colic. The latter feature was noted in about 25 per cent of the cases. Three of the patients had had previous operations on the biliary tract, two for cholelithiasis and a third for indeterminate obstruction to the common bile duct, for which cholecystoduodenostomy had been done.

The relation of pain to the development of jaundice in carcinoma of the pancreas is significant. It is often taught that tumors in this situation produce a painless type of jaundice. In our series some degree of pain has been present in all but three cases. Other authors report a similar incidence of pain. Judd and Parker, in a series of thirty-four cases, found that 38 per

cent of the patients did not have pain, 35 per cent had colic, and 24 per cent had dull, boring pain in the upper part of the abdomen. In Mussey's series, 88 per cent of the patients had either dull pain or colic. The pain rarely coincides with the onset of the jaundice as it does in cases of stone in the common bile duct, and the colic which the patients describe is usually atypical. Dull, boring pain, often referred through to the back, is an equally common type of distress.

In six of the cases of pancreatic carcinoma, jaundice was the initial symptom; pain appeared later. The duration of jaundice was notably brief; the average duration in this series was about fourteen weeks at the time the patients presented themselves for examination. As a rule, jaundice is persistent once it appears. In only two cases in this group was the jaundice intermittent and in one of them the original jaundice may have been of intrahepatic origin. The average level of serum bilirubin was much higher than that seen in cases of stone in the common bile duct or in stricture. In the majority of the cases the values for serum bilirubin were between 15 and 30 mg. Stationary or gradually rising curves of serum bilirubin were the rule. In the few cases in which values for serum bilirubin were low, there was often a history of hemorrhage to explain the low figures. Complete obstruction to the biliary passages is the rule, as Crohn has shown, but there are numerous exceptions. In sixteen of the cases bile was not obtained either in the stools or in the material from duodenal siphonage. Bile was obtained on drainage in four cases, and in two of these it was heavily mixed with blood. In three additional cases there was also blood in the material obtained by duodenal drainage. The finding of blood in the duodenal content is rare in benign lesions and not uncommon (20 per cent of our cases) in the presence of carcinoma. Crohn called attention to the value of this diagnostic point.

A distended gallbladder has been considered the most significant of the physical features which have been supposed to be diagnostic of carcinoma of the pancreas. In all of this group of cases the abdomen was carefully palpated to determine the presence or absence of this phenomenon. A definitely distended gallbladder was found in eleven cases. It was questionably palpable in seven additional cases, and was not enlarged in the remaining eight. In another series reported from the clinic,[3, 15] the gallbladder was palpably enlarged in about 50 per cent. A much higher percentage is described in figures from necropsy. The liver was uniformly enlarged in twenty of the cases in this group.

TABLE II

JAUNDICE DUE TO CARCINOMA OF THE PANCREAS (26 CASES)*

Relevant symptoms, signs and history	*Incidence per cent*
Previous operations on biliary tract	12
Colic	27
Dull pain	61
Minimal pain	12
Pain followed by jaundice	7
Serum bilirubin less than 10 mg. in each 100 c.c.	16
Serum bilirubin 10 to 20 mg. in each 100 c.c.	44
Serum bilirubin more than 20 mg. in each 100 c.c.	40
Biliary passages completely occluded	85
Biliary passages patent	15
Blood in duodenal drainage	25
Palpable gallbladder	55
Chills and fever	36
Pruritis	75
Prolonged coagulation time	40

*Ratio of males to females 4:1.

Perhaps the most significant point about jaundice due to carcinoma at the head of the pancreas is its progressive and persistent nature. Complete obstruction of the bile passages (as shown by absence of bile in the material obtained by duodenal drainage and by high fixed levels of serum bilirubin) is of great importance clinically, and a presumptive diagnosis often can be based on its presence or its absence alone.

Among the incidental symptoms may be mentioned pruritus, which was present in nineteen cases of the series, diarrhea, which was noted in eight, and melena, which occurred in three. In one case, ascites was a late development. In three cases the pancreatic tumors had evidently impinged on the duodenum; they provoked symptoms of ulcer in one case, and of partial duodenal obstruction in one case; a positive roentgenogram for duodenal ulcer was obtained in one case. Laboratory data did not give diagnostic information, although anemia was more common in these cases than in cases of jaundice due to benign obstruction; the concentration of hemoglobin was less than 60 per cent in about two-

thirds of the cases. An elevated level of blood sugar was found in two cases; other signs of pancreatic insufficiency were uncommon. In about 40 per cent of the cases, coagulation time was prolonged, usually ranging from ten to fifteen minutes. The relative frequency of the important diagnostic data in carcinoma of the pancreas is given in Table 2.

In biliary obstruction due to carcinoma of the gallbladder or ducts, the diagnostic signs are much less definite; in fact, we have no reliable diagnostic criteria concerning this group of cases. Rolleston had divided the symptoms of carcinoma of the gallbladder into three groups: (1) symptoms connected with preëxisting cholelithiasis; (2) the local effects of malignant disease of the gallbladder, and (3) complications due to invasion of adjacent parts by the tumor, and to metastasis in the liver, peritoneum and elsewhere. The small number of carcinomas of the gallbladder in our series (five cases) does not permit of conclusions. The usual predominance in females was noted, and also the long prodromal symptoms suggestive of cholecystic disease. It is well known that carcinoma of the gallbladder is rarely found in the absence of cholelithiasis; in all of our cases there had been symptoms suggesting cholecystic disease for a long time before the onset of jaundice. The development of jaundice in cases of carcinoma of the gallbladder indicates that the disease has reached a terminal stage. All of our patients were definitely cachectic, persistently jaundiced, and suffering from more or less severe pain in the right upper quadrant of the abdomen. Jaundice was usually of short duration and intense. Epigastric soreness, flatulence, nausea, and vomiting were constant. A tendency to hemorrhage was noted in all five cases. In two cases the gallbladder was palpable, and in one of the other cases there was a questionable mass in its vicinity.

Numerous reviews of large series of cases of carcinoma of the gallbladder appear in the literature, and the consensus of opinion is that there are no positive diagnostic signs, although pain, a palpable tumor, and complete and progressive jaundice in a cachectic patient are suggestive. Enlarged supraclavicular lymph nodes should be carefully sought. In one case biopsy of such a node established the diagnosis of malignancy and saved the patient a needless operation.

Our series of cases of jaundice due to carcinomatous obstruction of the bile ducts included eight of carcinoma of the common or hepatic ducts. Again, this series is too small to permit of conclusions. Marshall recently reviewed a series of forty-nine cases, which have been recorded at the clinic in the last twenty years.

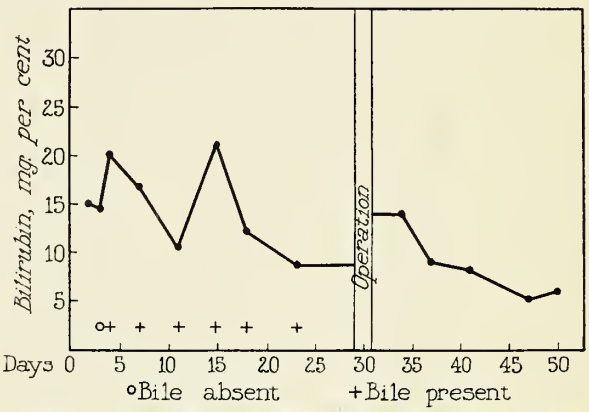

Fig. 3. Curve of serum bilirubin and results of duodenal drainage in a case of papillary tumor of the right hepatic duct.

From his data and from the series of cases reported by Outerbridge, Rolleston and McNee, certain points stand out. One is the predominance of the disease in male subjects (4:1). The age incidence is about similar to that noted in cases of carcinoma of the pancreas. Pain appeared to be less severe than in the groups of cases previously mentioned. In fifteen of Marshall's cases, the course of the disease was entirely painless, and in eight others the onset of jaundice was not accompanied by pain. About 40 per cent of the patients had atypical colic. As one might expect, obstruction to the biliary passages was usually complete. However, in two recent cases, there was a moderately free flow of bile on duodenal drainage; the tumors were situated in one or the other hepatic duct. The gallbladder was felt in nineteen of Marshall's cases, a fairly high incidence when one considers that seven of these patients had tumors of the hepatic ducts, which could not interfere in any way with the emptying of the gallbladder. In two of our eight cases, there was marked elevation of lipoid substances in the blood. In one of these two cases, obstruction was complete, whereas in the other case free flow of bile was obtained on duodenal siphonage. The curve of serum bilirubin and results of duodenal drainage in this last case are given in Figure 3. The fluctuating character of this patient's jaundice led to the suspicion that a stone was present in the common bile duct, and

exploration was advised. At operation a papillary tumor of the right hepatic duct was found. To summarize, it may be said that there are no reliable diagnostic signs in cases of tumor of the biliary passages, and one must be satisfied with establishing a diagnosis of malignant obstruction, without attempting to localize the lesion.

Although it is not possible to differentiate accurately the site of carcinomatous obstruction to the biliary passages, one is usually able to make a fairly accurate diagnosis of the condition in general. The atypical character of the pain, its lack of relation to the onset of jaundice, the persistence of jaundice once it has been established, the evidence of complete biliary obstruction, the cachectic appearance of the patient, and the progressively downward course, all are of great help in establishing a diagnosis. Gross blood in material obtained by duodenal drainage is almost pathognomonic. In our experience the effect of the jaundice on the patient also seems significant. In cases of stone in the common bile duct the attacks of jaundice are often well tolerated by the patient, in spite of the fact that most of these attacks are associated with definite signs of cholangitis. Obstruction due to carcinoma is essentially an aseptic condition, but it certainly has a far more serious effect on the general condition of the patient. This fact may be attributed perhaps to the high degree of hydrohepatosis, the resultant atrophy of the parenchyma of the liver, and to the injury which the carcinoma itself is producing.

TREATMENT

Without encroaching on the field of surgical colleagues, a word may be said about the surgical indications in obstructive jaundice. They are, briefly: (1) complete obstruction with distention of the biliary passages, with or without pain; (2) intermittent painful obstruction, and (3) doubtful conditions in which benign lesions are probable. These indications are necessarily rather broad. It has been said that the death rate from suicide of patients with complete biliary obstruction due to carcinoma is higher than the operative mortality for cholecystogastrostomy, a fact which one can readily understand when one observes the suffering from pruritus and pain which these patients undergo. Most cases of intermittent and painful obstructive jaundice are of benign origin, and there can be little doubt about the advisability of submitting such patients to operation. The third group encroaches on debatable ground. In any large group of cases of jaundice, there are many which can be diagnosed accurately only with the help of surgical exploration. When the question of surgical intervention is raised, it is the province of the clinician to appraise the severity of the risk and to do everything possible to reduce it by appropriate treatment. He should also assure himself that intrahepatic jaundice either is not present, or that it plays a minor part in the production of symptoms.

The four principal barriers to successful surgical care are renal and hepatic insufficiency, hemorrhage, and anemia. The first two are best avoided by the free use of solutions of glucose given intravenously. In our experience it is sometimes better to give solutions intravenously, before operation, than to wait for the actual development of trouble after operation. The value of glucose in obstructive jaundice recently has been reviewed by Ravdin. It may be said, however, that it is perhaps the most valuable single measure which we have at our command in caring for jaundiced patients. Since glucose has been more generally used it seems that deaths from renal and hepatic insufficiency are becoming less common.

The control of hemorrhage is still a problem. The use of calcium, as advocated by Walters, has been of great value, but it is not effective in every case. It should be emphasized that there is no demonstrable deficiency of calcium in obstructive jaundice.[4, 18] Nevertheless, calcium salts seem to exert a protective influence in hepatic lesions.[13] Transfusion is required in cases in which the hemorrhagic tendency is more severe and frequent repetition of this measure is often necessary. It has been noted[8] that there is an advantage in using a fasting donor and thus avoiding the reactions which jaundiced persons may show on receiving blood which is loaded with the products of digestion. Of the various anticoagulants which have been used, none has been of great value in our hands. Autohemotherapy, carried out by intramuscular injection, as suggested by Bollman, is more simple and practical, and deserves further trial. Irradiation of the spleen has had a large vogue in Europe, and seems to produce a good, although somewhat temporary, effect. Recently it has been

shown by Wright, Cowan and Hirschfelder that the use of concentrated solutions of glucose will elevate the concentration of blood calcium and will reduce the coagulation time in dogs with jaundice; Ravdin mentioned a somewhat similar phenomenon in human beings. In most cases of jaundice the measures just referred to will suffice to control hemorrhage. A small group of cases remains in which there seems to be an uncontrollable tendency to bleeding. Such a case recently has been noted at the clinic.[19] In this case there was reduction in the blood platelets as well as other signs of thrombocytopenia.

There are many minor points in regard to the care of patients with jaundice which are beyond the scope of this paper. One of these has to do with the selection of a time for operation. It has been noticed that the acutely jaundiced experimental animal is far more vulnerable than one in which jaundice has extended over a considerable period. The same may be said of the patient with jaundice, and care should be taken to avoid operation on patients in whom jaundice has been acute in its development or of short duration. Undue delay, on the other hand, may result in extensive hepatic injury. Each case appears to present an individual problem which must be acted on accordingly.

SUMMARY

An attempt has been made to show both the typical and atypical clinical characteristics of the various types of obstructive jaundice. In reviewing a series of this sort, perhaps the most striking feature is the fact that the atypical features are so common. This fact precludes a positive diagnosis in many cases of jaundice, and necessitates arbitrary division into surgical and nonsurgical cases. In all cases, however, the chances for diagnostic error are greatly minimized by a period of observation in hospital, a painstakingly accurate history in respect to pain, and the establishment of a curve of serum bilirubin to determine the intensity and the fluctuations in the jaundice. Such a period of observation permits one to determine the patency of the biliary passages by examination of the stools and by duodenal siphonage. It also establishes a better idea of the operative risk, and tends to reduce it as far as possible by permitting adequate preoperative preparation.

A SYNOPSIS OF THE TREATMENT OF CHRONIC ARTHRITIS*

George A. Williamson, M.D.
Saint Paul

THE treatment of chronic arthritis is one of the most complex of the problems in modern medicine. "Next to cancer, there is no more pressing medico-social problem than that of arthritis."[1]

The literature on the subject is burdened with glowing accounts of new drugs and the results produced by them. It is only after the physician has tried many of these new discoveries that he realizes how much better it is for him to adhere more closely to a saner routine, as more permanent improvement and actual progress is made by following such a course.

It is not intended that this paper will cover at all thoroughly the treatment of arthritis. The more strictly orthopedic aspect will be gone into in some detail and the other phases of treatment merely mentioned.

No time will be spent on the classification of the disease except to state that two forms are recognized. Proliferative arthritis, which is accompanied by such terrible deformities in younger people, and degenerative arthritis, which causes so much discomfort in older individuals, are to be considered.

In both types of arthritis, the treatment must be initiated by a thorough examination of the patient. Focal infection in teeth, tonsils, sinuses, prostate, and bowel are carefully searched for and, if found, are eliminated as thoroughly as possible.

Postural defects or other indications of faulty body mechanics should be remedied by the use of supports and supervised exercise.

The abnormally low basal metabolic rate present in 39 per cent of cases, according to Swain and Spear,[2] is treated with Lugol's solution or thyroid substance, and the lessened sugar tolerance found by Pemberton and others,[3] is favored by the administration of a low carbohydrate diet.[4]

The various drugs in use are too numerous to mention. It is found that sodium salicylate gives the maximum relief of pain and is not at all harmful. As there is no specific against the disease, the use of any harmless substance giving comfort to the patient is often all one has at his disposal.

Heat is a boon to all arthritics[5] and the method of administration not of the greatest importance. Best results have been obtained by the use of cabinets, or electric cradle baths, which, by their diaphoretic action, assist the general elimination. Local heat to the affected joints by the use of the electric baker, infra-red lamp, or diathermy helps to relieve the pain and diminish the swelling. A baker is very simple to construct and its usefulness unquestioned. As much heat as the sufferer requires is at all times available.

One other very important measure which must be emphasized is the use of foreign protein reaction produced by the intravenous administration of triple typhoid vaccine as suggested by Miller and Lusk, Albumose (Merck's) suggested by Kolmer,[6] Coley's Fluid,[7] and others. Very beneficial results have been obtained in cases which show signs of activity in the joints. The pain is quickly relieved, swelling in the joints subsides, and general improvement results in a definite percentage of cases. The method of administration is very simple. Beginning with 0.5 min. of triple typhoid vaccine (Minn. State Board of Health) intravenously, the doses are gradually increased 0.5 min. at a time, until 2 min. are given. Doses are given five days apart and in courses of five or six. The patient should be kept under observation, as the reactions are sometimes very severe.

Turning now to the more strictly surgical aspects of the disease, the thought of deformities immediately presents itself. Can these deformities be prevented and what can be done with them when they do occur? "We cannot prevent all deformities but we can prevent most of them," is a statement made by Pemberton.

The question of the prevention of deformities is one of prime importance, particularly to men in general practice. One of the great pleas made by all orthopedic surgeons is made to the general practitioner, begging him to apply splints of some

*Read before the annual meeting of the Minnesota State Medical Association, Duluth, Minn., July 16, 1930.

kind to every patient who is confined to bed because of any illness affecting his locomotor system. Much of our work in the treatment of arthritis, infantile paralysis and tuberculosis is the correction of deformities which could have been, to a great extent, prevented.

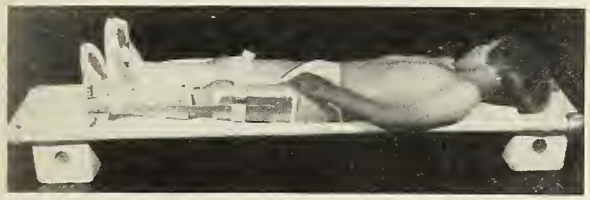

Fig. 1. Child is pictured fitted with splints holding the lower extremities in the position of optimum function. A sheet metal and strap iron splint fitted with felt pads and straps is shown on the left leg while a moulded plaster-of-Paris splint is shown on the right. A Bradford frame is used to keep the back straight and the hips from becoming flexed.

In the acute onset or in acute exacerbations of the chronic disease, pain is present in the joints on the slightest motion. The muscles, by going into spasm, attempt to relieve the pain by holding the joints immobilized. The powerful flexor muscles hold extremities in flexed positions and if these positions are allowed to persist, deforming contractures result. It is essential in joint disease to be aware of the possibility of ankylosis and, if this condition is to develop, to hold the joints in the position of optimum function.

May we consider first of all the splints available. Plaster of Paris, because of its great adaptability, probably ranks highest, with sheet metal splints, aluminum splints, and padded wooden boxes next in order. For the spine, a bed with two mattresses and boards between them and the springs to prevent sagging, is always available to everyone. Bradford frames and plaster beds are probably the most ideal. A leather and steel back brace of the Taylor type can be furnished for ambulatory treatment (Figs. 1 and 2).

A knowledge of the optimum position for function is very essential. For the shoulder the position is one of 75° abduction and 15° of forward flexion with the palm of the hand directed toward the face. If one elbow is involved it should be held at a right angle in the case of a man, and below this point if the patient is a woman. If both elbows are involved one should be held below and the other above a right angle. The wrist should be held in the more powerful grasping position, slightly hyper-extended. The hip is best if it is held abducted, externally rotated, and flexed a few degrees while the knee is best if held flexed 5 to 10°.

At this point a word of warning must be injected. The too prolonged fixation of joints is very harmful, as ankylosis will surely follow, whereas it might not have developed if motion

Fig. 2. A modification of the Jones abduction frame is shown. The method of keeping the feet in the right angle position, the knees in a few degrees of flexion, the hips slightly abducted and the back straight with the normal lumbar curve preserved, is clearly pictured. This splint is made of malleable iron so that any adjustments can be made as mild degrees of deformity are overcome.

had been started earlier. With the subsidence of pain and tenderness, the joints should be baked and moved gently both actively and passively. The efforts of the patient to move the extremities benefits both the joints and atrophied muscles. Pump-handling stiffened joints does much harm by producing denser adhesions in response to the vicious irritation.

Synovectomy and removal of loose bodies.—Thickening of the synovial membrane with formation of villous processes which project into the joint spaces is frequently found in chronic arthritis. Frequent pinching of these villous processes in movements of the joints results in repeated attacks of joint pain, synovial swelling and effusion. Synovial tags, osteophytes, or fragments of joint cartilage may become detached. These loose bodies are a constant source of annoyance by causing repeated catches or locking of the joint. Synovial swelling and effusion usually follow when these bodies become pinched. Swett[8, 9, 10, 11, 12] states that removal of the synovial membrane from a diseased joint has a threefold purpose: (1) it removes joint exudate which would not absorb by the usual channels; (2) it removes infected tissue which may be considered as a secondary focus of infection prolonging the disease; (3) it allows improvement in the general metabolism because of the early resumption of active exercise.

Excision of these fringes, as much of the synovial membrane and as many osteophytes as can be reached, or removal of loose bodies, is accompanied by marked relief. A careful and thor-

ough synovectomy is followed by a short period of rest until healing has taken place before vigorous physiotherapy is instituted. The physiotherapy referred to is chiefly active motion of the joint by the patient's own efforts but not to the extent of producing irritative symptoms. Early

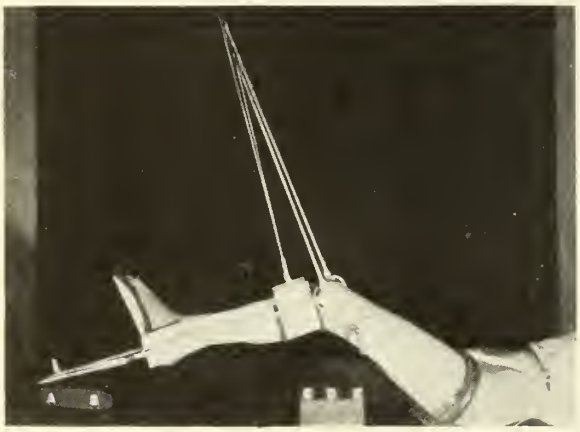

Fig. 3. The McMurray splint. An adjustable splint for the correction of flexion deformities of the knee is shown. Foot piece *B* attached to adhesive strips glued to the leg holds the foot at a right angle and rests on the side bars of the splint so as to prevent rotation of the leg. Traction downwards tending to straighten the knee is obtained by tightening the rope between the foot piece *B* and the lower end of the splint *A*. Traction upwards upon the upper end of the leg is made by tightening the rope passing from the felt pad *C* up over the top of the vertical pad of the splint. This pull prevents subluxation of the head of the tibia on the condyles of the femur as the joint is straightened. The direction of the traction on the extremity is changed as the knee straightens by adjusting the hinges *D* with the metal key *E*. Some of the muslin slings have been left off for the sake of clarity.

resumption of exercise after synovectomy results in general improvements in body metabolism, muscle tone, and physical comfort.

A patient who is willing to coöperate in the treatment of his disease need have no fear of a stiff joint following either of the above mentioned operations. J. Albert Key[13] has shown that there is replacement of the synovial membrane by a tissue of fibroblastic origin which takes on the function of the synovium.

If motion is present in a joint to such an extent as to be of definite functional value every effort must be made to preserve it. Frequently, due to the presence of a moderate flexion contracture, the motion present cannot be utilized. An example may be cited in the case of contracture of the knee joint. Frequently the joint is flexed so that weight bearing is impossible but there may be good available motion inside the angle of flexure. If the limb can be put in a position of good function and at the same time preserve the motion present, an excellent result will be obtained.

Frequently a joint stiffened by intra- or extra-articular fibrous adhesions retains a few degrees of motion. In this case the correction can be obtained through the joint itself. The method of widest acceptance is that of gradually stretching the contractures by the use of adjustable splints (Fig. 3) or plaster of Paris wedging dressings (Fig. 4). Either of these measures may be preceded by tenotomy of the contracted tendons causing the deformity. A carefully fitted, well padded plaster of Paris dressing may be applied to the extremity in the deformed position. A transverse cut is made through the full thickness of the plaster opposite the affected joint line on the side of the concavity. By insinuating wooden blocks of increasing thickness the flexion of the joint is gradually overcome as the gap in the plaster increases. Undoubtedly this is a method which is available to every practitioner. Splints of the adjustable type are very efficient but require careful observation and repeated adjustments as the deformities are overcome.

Silver[14] has shown very conclusively that the joint capsules play a large part in the maintenance of deformities. The denseness of the scar formation in these tissues practically prohibits its correction of contractures, and if forcible means are used the result is often a subluxation of the joint. By dividing the capsule on the side of flexion, contractures can be corrected completely, or nearly so, at once. The limbs are held for a short time in plaster of Paris and then immobilization is followed by use of physiotherapy directed towards active and passive motion. A warning must be issued against the complete correction of contractures if, by so doing, the vessels and nerves in the area would be put under too much tenson. The reason for the warning and the results which would follow are obvious.

Forcible manipulation of joints to correct contractures must be mentioned, but this method is not a safe one except in the hands of an expert.

A few degrees of motion in a diseased joint is very seldom of any functional benefit and only too often it is a cause of disability because of the accompanying pain. The problem of treatment in these cases is difficult. One must decide whether a firmly ankylosed joint in good functional position is more advantageous to the patient than a joint upon which an operation for the production of more motion has been attempt-

ed. It must be remembered that many of the arthroplastic and similar operations are followed by a recurrence of ankylosis. From the economic standpoint, the early ankylosis of the joint may be to the patient's benefit.

The operations designed to produce complete ankylosis in the joints are all fairly satisfactory. Probably the best procedure is the intra-articular fusion or arthrodesis. Extra-articular fusion may be obtained by a similar type of operation and as the joint is not opened the shock is not so severe. Fixation in plaster of Paris is maintained after operation until ankylosis has been obtained.

As regards the correction of deformities in joints which are completely ankylosed, much can be said. The methods to be used depend upon whether a movable joint, or a fixed joint in good functioning position, is to be the object attained. Osteotomies of the linear or cuneiform types allow the bones entering into the ankylosed joints to be placed in the desired position. Plaster of Paris dressings are applied to maintain the extremity in this position until union takes place. In many cases this is the most desirable procedure as it gives freedom from pain, an extremity in good position for function and an earlier return to work than is obtained in the other type of operation. The joints, however, remain firmly ankylosed.

Many operations have been described for the production of motion in ankylosed joints. A discussion of the various methods with evaluation of end-results is too big a subject to be considered at this time. There are a few general considerations which could be mentioned. If both hips are ankylosed an arthroplasty of at least one of the hips should be attempted. If this is successful the opposite hip may be operated upon at a later date. If the hip and knee of one extremity are ankylosed, an attempt to obtain functional motion in the hip should be made. The ankylosed knee would probably not be enough of a disability to make arthroplasty on this joint necessary if motion is obtained in the hip.

This brief summary would not be complete without at least mentioning some of the most recent work upon the problem. Reference is here made to the sympathetic ganglionectomy[15] introduced by Rowntree and Adson[16] in 1927. The work is highly experimental and remote results have not been observed. Changes in the extremities are chiefly due to the increased blood supply following the abolition of the vasomotor influence on the blood-vessels. Skin surfaces change from the cold, clammy, waxy appearance found in chronic proliferative arthritis to the warm, dry, ruddy complexion of normal skin. Joint

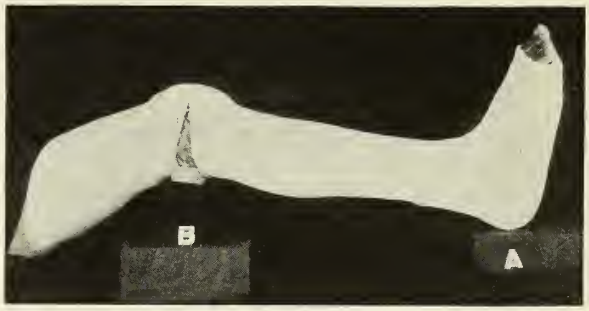

Fig. 4. This illustration shows the use of a plaster-of-Paris wedging dressing. A well padded plaster dressing is applied from the tips of the toes to high up on the thigh, holding the foot at a right angle and the knee in as much correction as can easily be obtained. By splitting the plaster through ⅞ of its circumference at the flexure of the knee wooden blocks of increasing width can be inserted between the edges of the cut in order to overcome the flexion deformity.

pain and joint effusion subside, probably due to the improved circulation. One of the questions which must be decided, however, before much enthusiasm is developed, is the ultimate outcome of the joints themselves. Can we expect to interfere radically with the sympathetic supply to blood-vessels, joints, and other soft parts without producing unfortunate end-results? What are the possibilities of the development of neuropathic joint disease like that found in tabes dorsalis, syringomyelia, and other similar conditions? Is the relief from pain, the comfortable warmth, and decreased swelling a permanent change or is it just a temporary one? It is felt that in carefully selected cases the procedure is worth trying and that efficient after-care and observation will bring many hopeful facts to light.

The treatment of arthritis may be summarized briefly:

1. The persistent search for foci of infection and metabolic and static disorders, and their correction.

2. Improvement of general health by supervised rest, diet, heliotherapy, etc.

3. Alleviation of pain in recently infected joints with local heat, and properly controlled fixation in splints and in the chronically inflamed joints by mechanical or operative fixation.

4. Relief of pain and swelling with increase

of motion in the joints by the use of triple typhoid vaccine to produce foreign protein reaction.

5. Restoration of motion when possible, by active and passive exercise or by operative means.

6. The correction of deformities.

7. Sympathetic ganglionectomy in properly selected cases.

UNDULANT FEVER*

E. C. Bayley, M.D.
Lake City, Minnesota

UNDULANT or Malta fever is an infectious disease. The infecting organism, known as *Brucella Melitensis,* may be isolated from the spleen, blood or urine. The exact mode of transmission is not known but has occurred from bovine, caprine, porcine and equine sources.

Although some cases may run an acute course and show a high percentage of mortality, yet the typical case is markedly protracted and of chronic or subacute character. The tendency of the febrile accessions to recur after an apyrexial interval accounts for the name undulant fever.

The typical case runs a course of three to four months or longer and the mortality rarely exceeds 2 per cent. Joint pains and neuralgia manifestations are fairly characteristic.

The causative organism, the *Brucella Melitensis,* is sometimes called *Bacillus Abortus* or *Bacterium Melitensis.* The causative organism of undulant fever in man, Malta fever in goats and abortion in cattle cannot be distinguished morphologically or biochemically.

Originally the infection was supposed to come from goats' milk only, but today ideas have changed. Individuals in various occupations contract it. But it seems most common in those who work with live stock, handle meat, or drink raw milk and cream. The method of infection seems to be varied and not infrequently it is impossible to trace the source of infection in a given case.

To date, eighty-eight cases have been reported in this state. Last year forty-two, and so far this year twenty-two have been reported. The increasing distribution of undulant fever suggests that the physicians are confronted with the necessity of familiarizing themselves with the symptomatology of the disease as they may be called upon to diagnose the condition. The fact that it may be transmitted by raw milk gives it geographically boundless limitation.

The diagnosis is by no means an easy matter inasmuch as the complete group of symptoms is not met with at the onset but is established by a slow evolution. The syndrome is incomplete until 5 or 6 weeks elapse from the beginning of the disease. The prodromal symptoms of undulant fever are malaise, anorexia, constipation, vague pains in the limbs, often so slight that the patient hardly notices them. Gradually they become more pronounced and ultimately the headache and interim lassitude compel the patient to forego his occupation and remain in bed. When this stage is reached the temperature is usually around 103 to 104. Most observers state that up to this time there are no respiratory symptoms, so influenza, for which it is frequently mistaken, may be eliminated early.

During the first wave of undulation of the fever the disease may be mistaken for typhoid fever although the two do not run courses that are in any way similar. In undulant fever there is rarely, if ever, any delirium, and constipation is the prevailing state of the bowels. In typhoid fever diarrhea and delirium prevail more often. Then the temperature curve is quite different from that in typhoid. It presents a well defined matutinal remission and the nightly fall of the temperature is invariably followed by more or less profuse sweating. After two or three weeks the diagnosis becomes less difficult and the patient presents nothing suggestive of a typhoid condition. His mental state is perfect in spite of the persistent high temperature; his digestive tract is unimpaired and is, in fact, in a better state than earlier in the attack; he has a particularly good appetite; and finally the Widal is negative and there has been no rash.

After persisting two or three weeks, undulant fever usually recurs and the patient enters the second undulation of fever. Such relapses recur for months and the disease may last for years. Various authors have reported cases in which the diagnosis was made from repeated agglutination tests, which have lasted from eighteen months to two years. Other cases have

*Read at the Sixty-second annual meeting of the Wabasha County Medical Society, Wabasha, Minnesota, July 10, 1930.

been known to terminate in from twenty to thirty days.

The spleen is usually enlarged in undulant fever and becomes palpable below the costal margin. It may be tender to pressure. A slight swelling of the lymphatics of the inguinal and cervical region has been mentioned by some.

Pain and swelling of the joints is present in about one-half of the cases reported. For this reason the disease is often mistaken for arthritis. The joint pain usually resists the medication to which rheumatic pains usually respond, and no tendency to endo- or peri-cardiac involvement exists. It is often hard to distinguish these pains from gonorrheal rheumatism, which they resemble in many respects. Not infrequently the serous exudate into the joints may be extensive and aspirations which have been made have made it possible to demonstrate the specific organism in the fluid withdrawn.

Undulant fever should be suspected in any case with an unexplained fever.

Subacute pyogenic infections are much more difficult to eliminate and a diagnosis may not be possible on the face of the negative blood cultures until embolic signs appear. Acute miliary tuberculosis in the early stages may cause confusion but the detection of old foci, the use of the *x*-ray and the course of the disease will eventually clear up the diagnosis. In this climate, where only the tertian form of malaria occurs, there should be no confusion with this disease. Hidden foci of infection might cause confusion but the blood picture is entirely different in most patients, for in undulant fever we usually have an anemia with a leukopenia, although the blood may be normal.

In about three-fourths of the cases cranial and facial neuralgia, lumbago and sciatica are mentioned in addition to arthritic pains. Some consider that epistaxis is a frequent symptom. Others insist that it does not occur early in the disease but is occasionally seen later in its course and in severe cases hemorrhages from the gums, intestines and even from the stomach have been reported.

Respiratory symptoms are quite common but are by no means constant.

The tongue becomes coated with a yellowish white fur early in the disease. The breath is usually fetid and the patient complains of a disagreeable taste in the mouth. The bowels are constipated.

Few symptoms of the disease suggest anything that may be spoken of as pathognomic, but many insist that the drenching night sweats are more typical than any which have been observed.

A summary of the symptomatology collected from even the recent contributions to the subject seems to suggest that the disease has many features which are atypical and were it not for the fortunate fact that the agglutination test with the dilution of the two organisms capable of producing the disease is available, a diagnosis would be practically impossible.

The eradication of the disease from a naval hospital at Malta by the boiling of the milk points to this important measure in the control of the disease. But it must also be remembered that the disease can be contracted from hogs, cattle, cheese, etc., so we must make an attempt to destroy all animals with the disease. All milk should be boiled or pasteurized. If no other reason existed for the pasteurization of all milk, the increasing prevalence of undulant fever would be an adequate one.

There is no drug that seems to have any influence on the course of the disease. Neoarsphenamine has been reported to be of value. The constipation should be corrected. For the insomnia and pains, hydrotherapeutic measures are indicated. Because of the length of the disease it is necessary to give a diet of sufficient caloric value. Some advise the use of vaccines and others have had no assistance from them.

Because of a mortality of only 2 per cent, there has been practically no autopsy material, so our knowledge of the pathology is not very exact. It is a bacteremia which can be demonstrated by blood cultures. So far as is known it does not cause abortion in women. The incubation period is thought to be about two weeks. It would seem reasonable to suppose that in the intestinal tract might be found the nidus of the infection if the entrance of the bacteria in many of the cases, and hypothetically in all, is by way of the mouth. It has been found by several observers that ulceration occurs in the small intestine in a small proportion of those dying from the acute malignant form. X-ray has shown definite irritability of the large intestine in a chronic case. This case immediately improved

and lost all symptoms when treatment was directed to the intestines. The sickness seems to be caused by the bacteria itself and not by a toxin, for injecting dead bacteria into cattle will cause no disturbance, while the injection of the live bacteria causes abortion.

Blood for examination should be drawn from the vein into a clean, small, empty bottle and sent to the State Board of Health, University Campus, Minneapolis. I use a Wassermann container and label it, "For Undulant Fever Agglutination." The State also examines it for typhoid, para-typhoid and tularemia.

Conclusions:

1. The *Bacterium Melitensis* will produce abortion in cattle and undulant fever in man.
2. The exact mode of transmission is not known.
3. The number of cases is increasing and it is very important that we familiarize ourselves with the various signs and symptoms in order to recognize it.
4. There seems to be no pathognomonic signs.
5. Undulant fever should be suspected in any patient with an unexplained fever.
6. Our knowledge of the pathology is not very exact.
7. The agglutination test as performed by the State Board of Health is the deciding factor.
8. The greatest point in treatment is prophylaxis. All animals harboring the disease should be destroyed. The barns and buildings that housed them should be cleansed, disinfected, and well aired. All milk should be boiled or pasteurized.
9. There seems to be no specific medication, vaccines having proved of little value.

REPORT OF CASE

The patient is a very obese woman of thirty-nine years, who has been enjoying good health until June 30, 1929. The day before, June 29, she went on a picnic and had strawberries and cream. That evening she felt very tired. The next morning, July 1, she awoke with a severe headache and pain throughout her back. She tried to do her washing but had to give it up for she felt so miserable. That afternoon her temperature was 101. At this point she went to bed. She did not feel hungry; her bowels were constipated. She ran this temperature and felt very miserable all week. Each day she thought she would feel better the next day, for she did not feel especially sick but just feverish and miserable.

I saw her first, July 7. At that time she complained of headache, backache, general malaise, a slight unproductive cough, chills and fever, and profuse night sweats. Physical examination showed only temperature 101, pulse 100, flushed face, coated tongue; the urine was normal. The condition remained about the same for several days. The blood Widal was negative but was positive for undulant fever agglutination.

About ten days after the onset the patient had a severe nose-bleed. On July 22 she began to have severe pains in the left leg and it began to swell and was edematous. She ran a fever of 99.5 in the mornning to 102 in the evening for eight weeks. Most symptoms cleared up after about five weeks except the swelling in the left leg, which still persists today to some extent.

This patient never drinks milk, and usually uses cream only in her coffee. She had cream on her strawberries the day before the onset of the disease. The herd furnishing the family with milk was tested and ten of the herd were infected with *Bacillus Abortus.*

CASE REPORT

ACTINOMYCOSIS OF THE MEDIASTINUM*

RUDOLPH C. LOGEFEIL, M.S., M.D.
Minneapolis

Although infection from actinomycosis is not at all uncommon in man, involvement of the mediastinum is comparatively rare. The following case is therefore of interest, and illustrates some interesting points in clinical diagnosis.

A school boy, H. J., aged 14, entered Fairview Hospital February 3, 1929, complaining of severe cough, swelling of the abdomen, shortness of breath even when sitting up, weakness, fever and sharp pains in the lower left chest.

History of Present Illness.—The boy was always healthy, though never strong, until nine months previous, when he had an attack of pleurisy in the lower left chest, which kept him in bed one month. He had no cough at this time, little if any fever, only severe sharp pains in lower left chest on deep breathing. He seemed to regain his usual health, but about three months later (September, 1929) he noticed a beginning weakness. Soon he noticed dyspnea on exertion with accompanying precordial pain. About December 1, 1929, he suddenly developed a severe irritating cough which never left him, but continued to grow worse. Two weeks later he noted his abdomen seemed enlarged. At Christmas time he had to go to bed because of another attack of pleurisy in the lower left chest. The dyspnea, weakness, precordial pain, cough, and swelling of the abdomen continued to increase up to the time of his entrance to the hospital. He saw several local physicians who treated him for heart trouble without relief of symptoms.

Past History.—He had always lived on the farm, and had never had any serious illnesses, operations or accidents.

Family History.—The father is forty-five years of age, living and well, but has clubbed fingers. The mother died at the age of thirty-eight, probably from pulmonary embolism, as death was sudden following a painful swelling of one leg. Three brothers and two sisters are living and well.

Physical Examination.—General inspection showed a greatly emaciated lad with drawn expression, orthopneic, cyanotic and annoyed by a persistent, dry, hacking cough. The eyes seemed sunken in his head, his pupils were dilated, but reacted somewhat to light and accommodation, were equal and regular. Mucous membranes were pale and cyanotic. Dental caries was marked and the tonsils were large and appeared infected. The tongue was coated and dry. The neck showed marked enlargement of many of the cervical glands, one on the right side being very conspicuous. Axillary and inguinal glands were not enlarged.

Configuration of chest showed a tendency toward the pigeon-breast type with marked depression of the intercostal spaces, and lower part of sternum. Tactile fremitus was somewhat decreased at both lung bases posteriorly, especially on the right side. Percussion over the lungs posteriorly showed fairly good resonance except at the bases and over the spine down to the eighth thoracic. Resonance in front was fair, but a large wide area of mediastinal dullness existed. Broncho-vesicular type of breathing of a very coarse character was generally present over the lungs in front and behind, with several small areas of bronchial breathing in both lungs accompanied by coarse, moist râles. Breath sounds were diminished at both bases with no evidence of passive congestion.

The apex beat of the heart could be seen and palpated indefinitely in the fifth interspace, in the anterior-axillary line. Percussion revealed marked general enlargement of the heart, especially to the right. The heart tones were clear, but weak and distant with a rough systolic murmur heard over the base. The pulmonic second sound was louder than the aortic second tone.

The blood pressure was 85-50; pulse 140.

The abdomen was very prominent and a large mass could easily be seen which filled the entire upper half. This proved to be, on palpation, a very hard, firm, tender liver with rounded edge. The spleen was also enlarged extending down to the level of the umbilicus. The small intestines seemed to be all pushed into a bunch over the lower mid-abdomen. The genitals were normal. The kidneys were not palpable.

The extremities were thin and there was some edema about the ankles. The skin was dry and shiny and the veins over the chest and abdomen were dilated. Reflexes were normal.

During the twelve days' stay at the hospital he ran a constant fever, varying daily from normal to 104 degrees on one occasion. It was of a septic type. The pulse rate varied from 100 to 160, respirations from 24 to 50.

Laboratory Findings.—Urinalysis on February 4 and 7 showed the specific gravity to be 1.029, albumin one plus, sugar none, microscopic negative.

On February 8 the phenolsulphonephthalein excretion was 50 per cent the first hour; 25 per cent the second hour.

Blood examinations were as follows: Feb. 4, R.B.C. 3,750,000; Hgb., 57 per cent (Talquist); W.B.C., 14,400 with 90 per cent P.M.N. Feb. 5, blood smear, 90 per cent P.M.N. Feb. 8, W.B.C., 15,500. Feb. 13, blood culture negative. Feb. 14, R.B.C., secondary anemia

*Read before the Minnesota Society of Internal Medicine, at Duluth, Minn., May 26, 1930.

type; 82 per cent P.M.N. Feb. 16, Wassermann negative.

It was learned at this time that the boy had been in the University Hospital for a few days prior to entering Fairview Hospital. No final diagnosis was arrived at by the doctors there, however, as he left under protest before the examination had been finished. Their impression, however, was that he had a malignant tumor of the liver and a mediastinal tumor, probably lympho-sarcoma.

The first *x*-ray pictures were taken at the University Hospital on January 31, 1929. Dr. Rigler's report was as follows:

1. Mass in mediastinum, probably lympho-sarcoma.
2. Pleural effusion, right.
3. Intra-abdominal mass, probably associated with liver.
4. Bilateral maxillary sinusitis.

On February 5, 1929, *x*-ray pictures of the chest and sinuses were taken at Fairview Hospital, which showed a greatly enlarged heart, a mediastinal mass, and a small bilateral pleural effusion (Fig. 1). There was bilateral maxillary sinusitis. Fluoroscopic study of the chest by the author showed a marked general enlargement of the heart with some preponderance of the right ventricle, as noted in the left anterior oblique position. No enlargement of the auricles was noted. Electrocardiographic study showed a tachycardia (150), right ventricular preponderance, arborization block, grade I, and inverted T_3.

From these clinical and laboratory data, the following diagnoses were made:

1. Cervical and mediastinal adenopathy, probably a lympho-sarcoma or Hodgkin's disease.
2. Mediastinal pressure syndrome.
3. Adhesive pericarditis with constriction of the inferior vena cava, with resulting passive congestion of liver.
4. Passive congestive type of decompensating heart.
5. Bilateral pleural effusion.
6. Low grade type of broncho-pneumonia.
7. Bilateral maxillary sinusitis.

The diagnosis of mediastinal pressure syndrome was made on the presence of an early Horner's sign (stimulating pressure on sympathetics), marked dilatation of the veins in the neck with cyanosis, and the extremely irritating cough. The impression of constriction of the inferior vena cava was based on the clinical findings of extreme passive congestion of the liver with little or no passive congestion in the lungs, in the absence of tricuspid and pulmonary stenosis, which may give similar findings.

The bilateral pleural effusion was explained on the basis of pressure from the mediastinal tumor mass on the hemiazygos and azygos veins.

Removal of a recently enlarged cervical gland for microscopic study was advised, but this was refused.

The condition of the boy continued to grow worse each day. There was little or no response on the part of the heart to digitalis, caffein-sodium benzoate or coramine. The administration of salyrgan in one to two c.c. doses intravenously and euphylin by mouth resulted in moderate, temporary diuresis. Sedative cough mixtures had no effect. On February 11 the temperature reached 104 degrees and the type of breathing changed to that commonly seen in pneumonia. Many râles now were present all over the chest, with several definite areas of broncho-pneumonia. Death ensued two days later.

In view of the previous attitude of the relatives, we

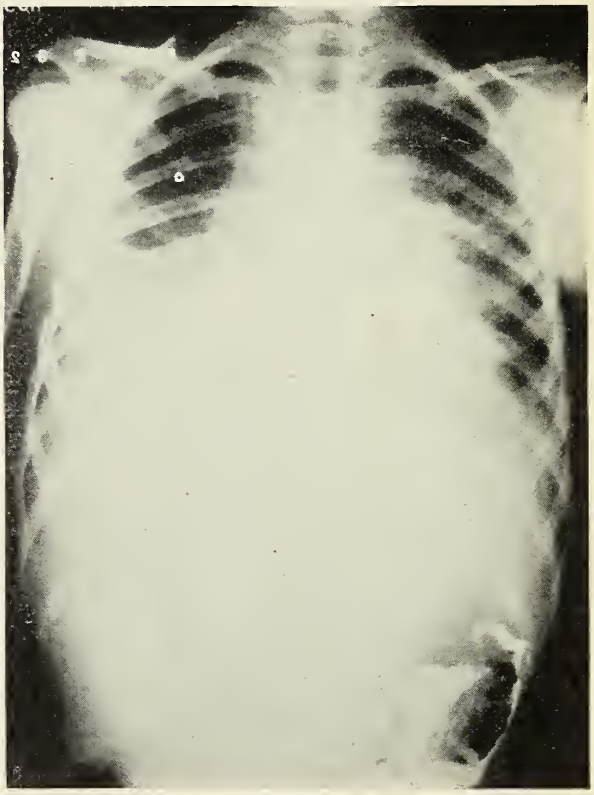

Fig. 1

were delightfully surprised to obtain permission for a post-mortem examination. This was made by Dr. Paul H. Cuttman, and his report is as follows:

"The body is that of a well developed, emaciated white boy, 150 cm. in length and weighing about 85 pounds. Rigor is moderate, there is purplish hypostasis posteriorly, slight edema about the ankles, no cyanosis or jaundice. The pupils are equal, regular and in mid-dilation. The abdomen is very prominent and tense. The veins over the abdomen, chest and neck stand out prominently. There is marked enlargement of lymph nodes in the anterior cervical region.

"The abdominal fat is scant. The abdomen contains about 450 c.c. of clear, straw-colored fluid. The liver reaches 12 cm. below the costal margin in the right mid-clavicular line. The appendix shows a marked kink in its proximal third; it is below the cecum and is not adherent to the surrounding tissues. The diaphragm is at the seventh interspace on each side.

"Each pleural cavity contains about 750 c.c. of brownish fluid containing occasional fibrin flakes. On removing the chest plate numerous pus pockets are en-

countered over the mediastinum. The entire mediastinum and the pleura over the anterior half of the right side and adjacent mediastinum on the left are markedly thickened and indurated. The mass is composed for the most part of a firm, grayish tissue, containing pus pockets varying in diameter from a few millimeters to 2 cm. The thymus is lost in this fibrous mass. The medial surfaces of the lungs, the pericardium and the

Fig. 2

great vessels leading to and from the heart are matted together in this mass. The pericardial surfaces are firmly adherent and cannot be separated. The pericardial space is obliterated.

"The heart is left *in situ* and not weighed. The myocardium is of a light brownish red color and shows no evidence of hypertrophy. The endocardium shows no change. The valves appear normal. The root of the aorta shows no evidence of arteriosclerosis and the coronary orifices are widely patent. The superior vena cava is not obstructed. The inferior vena cava near its opening into the right atrium is reduced to a small diameter by fibrous growth about it; it will scarcely admit the small finger.

"Each lung is markedly atelectatic; crepitation is almost absent throughout. The surfaces are dark purple color. On section the surfaces are meaty and red. The upper and middle lobes of the right lung show increase of fluid and grayish red mottling. A small amount of purulent material can be expressed from the small bronchi.

"The spleen weighs 140 grams. The capsule is fairly smooth. The surface is smooth and of a slate blue color. The substance is soft and brick red; it scrapes readily. The corpuscles are indistinct.

"The liver weighs 1,725 grams. The surface is smooth and of dark purplish color. The edges are slightly rounded. The organ sections with normal resistance and the substance is firm; it shows typical nutmeg appearance throughout. The gall bladder is of normal size and color and contains a stringy greenish bile. The bile passages show no lesions.

"The gastrointestinal tract, pancreas and adrenals show no lesion.

"The right kidney weighs 160 grams, the left 190 grams. The surfaces are smooth. The capsules strip readily. The color is pale grayish red. On section the edges evert slightly. The cortex is pale and cloudy; the medulla is slightly darker; shows no gross lesion. There is no change in the pelvis, ureters, bladder or prostate.

"The lymph nodes about the aorta are increased in size, firm, and grayish white; there is no breaking down of the tissue.

"The aorta is smooth throughout. The organs of the head and neck are not examined."

Microscopic Examination.—The first tissues examined from the lower part of the mediastinum and the pericardium showed marked inflammatory reaction, consisting of connective tissue and polyblastic infiltration; small abscesses containing abundant polymorphonuclears in the center surrounded by connective tissue. This was interpreted as a chronic suppurative inflammatory lesion but, because of the gross peculiarity of the lesion, further sections were made from places showing multiple small abscesses, and these are found to contain small abscesses surrounded by epithelioid cells and connective tissue and containing in the center typical actinomycetes (Fig. 2).

Diagnoses.—

1. Mediastinal actinomycosis.
2. Chronic suppurative pericarditis and pleuritis.
3. Stenosis of inferior vena cava by contraction of scar tissue.
4. Ascites; bilateral hydrothorax.
5. "Nutmeg" liver.
6. Cloudy swelling of kidneys and heart.
7. Septic spleen.

Comment.—Next to the face, the neck is the most frequent site of actinomycosis. The primary lesion is often cicatrized and only scar tissue remains as evidence of the original infection. The disease is not spread by blood or lymphatics, but by continuity. The tissue is destroyed and liquefied, and the picture is one of induration, areas of suppuration, sinuses and fistula formation. Although no definite sign of a previous initial lesion could be found about the face or mouth in this case, there were plenty of enlarged infected cervical glands, which deeply invaded the lower part of the neck. Actinomycosis of the mediastinum is always secondary, and from these deep-lying glands the infection extends along the loose connective tissue of the sheaths of the great vessels to the mediasta.

Most authors agree that involvement of the anterior mediastinum is rarer than that of the posterior. In my case the entire mediastinum was involved. Extension is usually first to the posterior mediastinum. Through the mediastinum, extension may occur to the pleuræ, lungs, heart and pericardium. Because of improper drainage from these deep parts, the disease is very serious when involving any of these structures. According to reports in the literature, diagnosis is rarely made antemortem. I believe a diagnosis would have been made in my case if a cervical gland could have been removed. However, the condition should have been thought of and considered in view of the boy having lived in the country on a farm, and exhibiting such extensive involvement of his cervical glands. He exhibited what has been called the neoplastic type which is characterized by an abundant proliferation of connective tissue which, without the presence of mycelium, is difficult to differentiate from round cell sarcoma. However, when the actinomycotic nodule broke down, small abscesses were found containing pus and the characteristic yellow granular bodies. These were fairly numerous substernally and in the posterior mediastinum.

Tuberculosis and syphilis are usually considered in the differential diagnosis of actinomycosis, but in my case, lympho-sarcoma and Hodgkin's disease were also included. The presence of a polymorphonuclear leukocytosis should have directed me to a suppurative process other than tuberculosis. The absence of a draining sinus made the diagnosis more difficult. Van Den Wildenberg refers to a complement deviation reaction as a means of diagnosis, because the serum of the person with actinomycotic parasitosis contains specific antibodies.

The diagnosis once established, treatment should consist first of a trial with large doses of potassium iodide internally and injected into the infected areas in strengths of 1 per cent. This has cured many of the superficial cases. The drug is not a specific in the true sense of the word, but acts rather on the neoplastic tissues causing them to undergo a rapid breaking down and thus more quickly to establish drainage to the surface. Other methods advised are deep roentgen-ray therapy, autogenous vaccines and Yotren.

1111 Nicollet Avenue

PRESIDENT'S LETTER

A CONSIDERABLE number of years ago there was a great deal of agitation over child labor conditions, particularly as they obtained in the south. This resulted in Maternal and Child Hygiene legislation by the national legislature. The object of such legislation was to control and abolish child labor. Though commendable in purpose the supreme court ruled that the law was unconstitutional inasmuch as it attempted to regulate matters that properly belonged under state rather than national control.

The next legislative action attempted to get control of the situation by taxation. When this law was carried to the U. S. Supreme Court the same ruling was handed down as in the case of the preceding law. The next step was the enactment of the Sheppard-Towner Maternity and Infancy Act, approved November 23, 1921. This law sought to evade the constitutional strictures placed upon the two preceding laws by offering to purchase, from individual states, the privilege to coöperate with them in providing for the health and well-being of mother and child. Incidentally provision was made for conditions to which each state desiring federal aid in the management of its own affairs would be obliged to subscribe in order to obtain the proffered financial aid. Thus was Federal domination of state activities insured to the national government. All of this legislation was endorsed by the U. S. Department of Labor and the administration of it was placed in the hands of the Children's Bureau of that department. The supreme court has never had occasion to rule upon the constitutionality of the Sheppard-Towner Act.

The chief objection to this act is that, in spirit, it violates certain constitutional guarantees which delegate to the several states, rights and obligations to regulate affairs that are clearly within the province of each state. The act is primarily a labor law masquerading as health legislation and diverted in its administration to the promotion of the health and safety of women in pregnancy and confinement as well as to the health and safety of the new-born. No one can complain of the purposes of this law, either in conception or operation. The law meets with opposition, as stated above, on constitutional grounds. Also because it seeks to transfer the practice of medicine from the individual to the hands of the state; from professional influence to lay domination; from the unbiased guidance of science to that of a centralized political bureau. Inasmuch as the Sheppard-Towner Act and similar laws seek to lower maternal and infant mortality it is only right that we should know the mortality rate and if it can be lowered. Without submitting figures it may be stated that the present rate is very much too high and that it is due to almost entirely preventable causes, namely eclampsia and infection. It has been stated by reliable authority that maternal deaths from these two causes alone can be reduced by at least two-thirds.

Question.—Is the medical profession going to effect this reduction? If it is not going to answer this question in the affirmative let it acknowledge its insufficiency and its indolence, accept Sheppard-Towner legislation with all its iniquities, and permit the state to demonstrate its superior ability. Our prospective mothers are entitled to every safeguard and protection in the crowning hours of their existence. If we will not do our full duty let us not complain if the public does it for us.

It is high time that we awaken to our responsibilities in relation to maternal welfare. These responsibilities are not collective only, they are also individual. Every doctor in every city, village, hamlet and cross-roads should strive, and strive earnestly, to prevent these death dealing afflictions to which maternity is exposed. No effort should be spared, no opportunity lost, by any doctor to teach his people the value of prenatal care. Every doctor knows the conditions leading to infection and he knows how to prevent or correct them; he knows the signals of approaching eclampsia and he knows how to avert the danger. Let each and every one, whether specialist or general practitioner, act on this knowledge and so reduce the maternal death date.

We are charged with the responsibility of safeguarding our women through maternity. We must prove ourselves worthy of our trust. Whereas the state seeks to make an organized effort to do this work, we fail to do so. We take an active and organized part in heart problems, lung problems and economic problems, and now why not in obstetric and maternity problems? The prevention of maternal sickness, misery and death is an inviting field, offering great possibilities and glorious reward. Every component society in the state should organize an educational movement of this kind. It would be well if the University Extension service, obstetric societies and the State Medical Association would coöperate in putting such an educational movement into effect.

S. H. Boyer

President,
Minnesota State Medical Association.

INTER-STATE POSTGRADUATE MEDICAL ASSOCIATION

The attention of Minnesota physicians is again called to the meeting of the Inter-State Postgraduate Medical Association which takes place in Minneapolis this month.

The scientific program is already in the hands of our members and speaks for itself. The quality of the clinics and addresses can be judged from the names of foreign, Canadian and American leaders that appear in the program. Those who attended the Saint Paul session in 1925 or other former meetings of this Association know what to expect. Almost without exception the program will be furnished by professors or associate professors from medical schools here and abroad.

Five strenuous days of clinics and addresses have been planned. The program will begin at 7:30 each morning and will continue morning, afternoon and evening until the banquet on the evening of the last day.

As at former sessions, the association meets as a unit in one general assembly where subjects of general interest will be presented. In this respect the Association differs somewhat from the A. M. A. meetings and is meeting a distinct demand, as evidenced by the rapidly increasing attendance at its meetings in recent years. The meeting, as the name signifies, is in the nature of a post-graduate course and a lot of authoritative information will be crowded into the five day session. To be a well informed physician the specialist as well as the general practitioner needs this sort of instruction.

PHYSICIANS AND ADVERTISING

Advertising is contrary to the code of medical ethics. The same rule applies to all professions and this is one of the outstanding differences between a profession and a business. While the physician is perforce dependent upon his fees for his livelihood, monetary return is not and should not be the prime consideration. Advertising smacks too much of a purely business proposition.

In a recent editorial the *Minneapolis Journal* takes the profession to task for not changing its code of ethics regarding advertising. The editor thinks we should use this same tool which quackery has so misused and that the public suffers because we fail to inform them as to what we have to offer for the alleviation of physical ills. We cannot agree that the public would be better served if physicians began to advertise.

The physician depends on the quality of service rendered to increase his practice. Of course

there are a number of modifying factors which affect the size of a practice such as personality, association, medical jobs, etc., in addition to scientific ability. Would advertising be of benefit to the public in assisting the able and not the inefficient physician to increase his clientele? We think not.

What would we advertise? Our specialties? Then how about the general practitioners? The diseases we can cure? This presupposes a diagnostic ability on the part of the patient. Or perhaps we should publish our faces? Not so good.

Obviously the newspapers would all favor the adoption of advertising by physicians. How about increasing the cost of medical service? The prohibition of advertising places no physician at a disadvantage.

Most publicity amounts to advertising. This is the reason that the physician to be consistent is inclined to sidestep publicity. This does not mean that the public is deprived of medical information. What with health journals such as *Hygeia* and the *Public Health Journal,* radio broadcasting by national and state medical associations and health articles in newspapers and magazines, the intelligent reader can easily keep posted.

The newspapers themselves are to a certain extent to blame for the usual reticence on medical matters encountered by them. Information, when given, is likely to appear in a distorted, sensational write-up featuring the individual rather than the subject matter. The public is interested in individuals rather than abstract facts, we are told.

Medical groups—so-called clinics—are bound by the same rules of ethics as individual physicians. Articles sometimes appear without the sanction of the individual physician or the group, but not infrequently a group utilizes publicity methods or even solicits patronage in a manner that would be severely criticized in an individual. A hospital sometimes advertises and incidentally the medical group which owns or patronizes the hospital receives publicity. A hospital, in our opinion, should not be operated as a money-making proposition and therefore should not resort to advertising in lay magazines or newspapers.

No, we can see no reasons for changing the status quo of medical advertising and there are many reasons why we should continue to play the game according to the present rules.

MOMENTS OF REST

Men do die of overwork. The young engineer, Holland, and his successor, Freeman, both died probably of overwork during the construction of the Holland tunnel under the Hudson River. The way a man spends his hours away from the office, however, is the theme of this discussion.

Competition was never more strenuous. It becomes apparent in pre-college days, is severe in undergraduate days and becomes most intense in business and professional life. Happy is the individual who learns early how to spend his hours while away from work so as to conserve his energy.

Hobbies are a great asset. But Lord Dawson was right when in a recent address at Winnipeg he warned against the danger of overdoing even the game of golf. He believes many a middle aged man is better off with one round of golf over the week end with plenty of rest, rather than with three rounds and little or no physical relaxation.

How many men return from a so-called hunting trip refreshed? The unaccustomed physical exercise, lack of sleep, and excessive indulgence in drinking and smoking, so commonly accompaniments of an outing, all tend to drain reserve and leave the individual susceptible to infection.

Vacations should be taken by everyone. And yet how often they are spent in ways that are tiring rather than restful. A nerve-racking run may be made by auto across the country or the vacation may be made to assume the nature of a celebration rather than a vacation.

Daily routine which provides for proper physiological rest is most important. The busy man realizes the importance of early to bed. The present day party that begins at bed time and ends at the usual rising hour is a man killer and incompatible with serious work.

The busy man can well afford to break the day by taking the full noon hour for lunch and relaxation, or by even going home for lunch and resting a few minutes after the noon meal. A few are even able to snatch a few minutes of refreshing sleep before returning to the fray.

When middle age is reached, the type of exercise may well be modified. The man following a sedentary occupation is better off if he leaves the more strenuous forms of exercise alone.

Sudden death in the forties from heart disease seems to be on the increase. It certainly has been called to our attention most strikingly of late.

This must be the result of unnecessary wear and tear on the human organism and sclerotic coronary arteries are at the bottom of many of these tragedies.

Shall we eat, drink and be merry for tomorrow we die, or shall we use a little more common sense?

OF GENERAL INTEREST

Dr. H. B. Bayley, formerly of Ceylon, Minnesota, has moved to Fairmont.

Dr. Willis Herbert is practicing at Maynard, Minnesota, following an interneship at St. Mary's Hospital, Minneapolis.

Dr. Philip A. Halper has moved from Saint Paul to Chicago, where he has opened offices at 30 North Michigan Avenue.

Dr. Herbert K. Kent, who completed his interneship at St. Barnabas Hospital, Minneapolis, recently, has located in Portland, Oregon.

Dr. Harlan Alexander has recently become associated in practice with Dr. H. M. Lee in the Physicians and Surgeons Building, Minneapolis.

Dr. Phil Quilling, following his interneship at Asbury Hospital, is assistant to the surgeon for the Great Northern Railroad at Marquette, Michigan.

Dr. Junius Smith, following interneship at St. Barnabas Hospital, Minneapolis, this year is a member of the Medical Corps of the United States Army.

Dr. H. Paul Johnson has established offices at Seventh Street and Eight Avenue South, Minneapolis, for general practice. Dr. Johnson did his interne work at Asbury Hospital.

Dr. Evelyn McLane, who completed her interneship at Asbury Hospital, Minneapolis, this year is associated in general practice with her husband, Dr. Will McLane, at Sleepy Eye, Minnesota.

Dr. N. J. Berkwitz is no longer associated with Dr. W. A. Jones of Minneapolis. He has recently opened a private office in the Medical Arts Building and is limiting his practice to nervous and mental diseases.

Dr. James R. Kingston has located at Grand Rapids, Minnesota, where he is engaged in general practice. Dr. Kingston was an interne at the Abbott Hospital, Minneapolis, where he completed his course July 1.

Dr. E. J. Borgeson of Minneapolis addressed the Chisago-Pine County Medical Society, August 26, at Pine City, on "Diagnosis and Treatment of Chronic Sinus Infections." Dr. C. G. Kelsey of Hinckley read a paper on "Eczema of the Scrotum."

Dr. Sherman Stenberg, who recently completed his interneship at St. Mary's Hospital, Minneapolis, has been practicing in Sisseton, North Dakota, doing relief work for a local practitioner there. He is planning to establish a practice in Hudson, Wisconsin, later.

Dr. J. Allen Wilson has become associated with the Earl Clinic, Saint Paul, after a year spent under Dr. Ralph Brown in gastro-intestinal work at the Presbyterian Hospital in Chicago. The preceding year Dr. Wilson interned at the Ancker Hospital, Saint Paul.

Word has been received of the death of Mrs. Alice Hanson Magnuson, wife of Dr. Paul Magnuson of Chicago. Both Dr. and Mrs. Magnuson lived in Saint Paul before Dr. Magnuson took his medical course and located in Chicago, where he became interested in surgery.

Dr. and Mrs. Clifford E. Alexander of Duluth have left for an extended visit to Vienna and other European clinics, where they expect to remain for about ten months. Dr. Alexander's practice at Duluth is being cared for in his absence by members of the Arrowhead Clinic, of which Dr. Alexander is a member.

Dr. William C. Wright and Dr. Richard L. Hane, formerly associated with The Mayo Clinic, Rochester, have announced the opening of offices in the Medical Arts Building, Fort Wayne, Indiana. Dr. Wright is limiting his practice to general and urological surgery; Dr. Hane to general surgery and surgery of the thyroid.

Dr. Arthur C. Strachauer sailed from New York, September 23, on the steamship Bremen for a tour of Europe and the Orient. He will visit the important surgical and cancer centers at Berlin, Vienna, Munich, Paris and Rome. On the return voyage he will stop at Bombay, Shanghai, Pekin and Honolulu, and will arrive in Minneapolis about April first.

Dr. Leo G. Rigler, with his associates, was awarded the Southern Minnesota Medical Association medal for the best scientific exhibit at the annual meeting of the Minnesota State Medical Association held at Duluth in July. The exhibit, which won the award from the standpoint of originality, practicability and manner of presentation, was a demonstration by roentgenograms of free and encapsulated pleural effusions.

Of the internes who completed their work at St. Mary's Hospital, Duluth, the past year, the following have established practice in the towns and cities mentioned: Dr. Warren Fetterly, Medical Arts Building, Minneapolis; Dr. E. E. Zemke, Fairmont, Minnesota; Dr. O. E. Sarff, Baudette, Minnesota; Dr. W. A. Stafne, Fargo Clinic, Fargo, North Dakota; Dr. N. Lende, Faribault, Minnesota; Dr. R. R. Sullivan, State Department of Health, University Campus, Minneapolis; Dr. V. J. Telford, Edgerton, Minnesota.

CONSULTATION BUREAU

WM. A. O'BRIEN, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question.*—Please outline the treatment for a case of syphilis in the secondary stage. The patient has not had any previous treatment.

   Answer.—The first course of treatment consists of twelve Bismogenol injections of 1 c.c. each into the muscles once every five days. Five days after the last treatment has been given, the neosalvarsan intravenous injections should be started. Give six treatments of not more than .6 grams each one week apart. Three such series of treatments are given the first year, and two in the second and third years.

2. *Question.*—I wish to purchase a carbon dioxide snow apparatus for the treatment of warts. I will probably not use it more than once a month. Please tell me about the least expensive apparatus I can purchase for this purpose.

   Answer.—To make carbon dioxide snow pencils it is necessary to have a tank of carbon dioxide, which is purchased but may be exchanged for another tank, and an adapter for the end, which is a separate piece of apparatus. If you do not intend to use carbon dioxide snow very much, why not get a small cautery? Warts may be treated in this way very successfully. In addition the cautery may also be used for other purposes, including a cauterization of the cervix in cases of chronic cervicitis. This is a splendid way, according to available knowledge of preventing many cases of malignancy of this structure.

3. *Question.*—Again I am taking advantage of your new and convenient department to ask some assistance in a distressing case. A Jewish boy of about twenty-five years has very painful feet which he describes mostly as "burning like fire." When I first saw him I noticed a large amount of callus, which I removed with no apparent benefit. I have had him using tannic acid and it has been of no effect. There is no apparent localized tenderness as in a frank metatarsalgia and no localized flushing as one would find in erythromelalgia. There is no great amount of sweating and, in fact, the most characteristic finding is the normal appearance of the feet. Yesterday I gave him some luminal in Porter's solution, which is a modification of the lead and opium wash and, of course, I do not know what will come of this.

   Answer.—Indefinite burning pain in the feet of any young adult requires a careful examination to rule out possible circulatory disturbance. The fact that this boy is Jewish would make such an examination almost imperative as a diagnostic procedure. I would suggest that the patient be stripped and placed in a sitting position on the edge of a table and palpation of the posterior tibial and dorsalis pedis arteries be carried out bilaterally with an estimation of the pulse pressure by palpation. They might be compared with the radial arteries. With the knees flexed and the muscles relaxed the popliteal artery should be palpated. With the feet dependent, cyanosis or reddening should be noticed. The patient should then lie down and the feet be slowly elevated. If they blanch before they have reached 45° elevation poor circulation is probable. If the patient then contracts all the muscles of the feet (making a fist, so to speak) with the feet elevated, the finger of the examiner can block the posterior tibial artery behind the internal malleolus. Then the patient sits up and hangs the feet over the edge of the table with the artery blocked and an observation is made of the rapidity of returning circulation in the toes, especially the great and second toes. If these remain blanched, there is probably peripheral blocking of the collateral arteries. If there is a history of claudication or cramps in the calf muscles after exercise plus any of the simple examination findings above, I should be very suspicious of endarteritis obliterans, or Buerger's disease. The treatment of this condition depends upon its severity. If there is a spastic element, that is, incomplete blocking, but marked vasomotor changes of a transient but painful character, lumbar sympathectomy is indicated. The indications, however, are dependent upon circulatory efficiency tests measured by special thermometers after foreign protein temperature shocks. Needless to say, protection of the extremities from over-exertion, strain, or irritation of any type is essential. If the case is not serious, good temporary results often occur following the use of intravenous injection of typhoid vaccine in doses of 50 million to 150 million at 4 day intervals over a period of three weeks. Twenty-four hour hospitalization is necessary for each dose, and the good effects require a rather marked temperature rise.

   Other diagnostic possibilities are:

   1. Raynaud's disease. Patients with this condition are usually females and the attacks are provoked by cold. You did not state in your question what produced the pain or whether it was constantly present.

   2. Peripheral neuritis. This is usually unilateral and involves either the peroneal or saphenous nerves.

   3. Verruca plantaris under the calluses. They would cause a great deal of discomfort and may be found by examining the surface after the calluses are removed.

   4. Arsenical dermatitis might produce lesions, but there would be a history of the drug.

   The consensus of opinion seems to be that the patient has a vascular disease, and the most likely type is Buerger's disease.

MISCELLANEOUS

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

Indian Doctor Given Sixty Days in Jail

State of Minnesota *vs.* Starr

On August 26, 1930, Lester Starr was arrested at Spring Grove, Minnesota, charged with practicing healing without a Basic Science certificate. The defendant was a member of a group of Indian doctors who were selling roots and herbs in Fillmore and Houston Counties for the past two months. Their charges ranged from ten to sixty dollars per person and it has been conservatively estimated that they took in $4,000 during the time they were in that vicinity. The defendant waived his preliminary hearing and was held to the District Court under bond of $1,500, which he was unable to furnish. On September 9, Starr entered a plea of guilty before the Hon. Karl Finkelnburg, Judge of the District Court. The Court sentenced the defendant to sixty days in the Houston County jail. The Court denied a plea for a suspended sentence, which means that the defendant will have to serve his time.

Excellent coöperation was received by Mr. Brist, representing the State Board of Medical Examiners, from William E. Flynn, County Attorney, and Arthur C. Brown, Sheriff. It is also felt that Judge Finkelnburg is to be highly commended for his fair but firm attitude in dealing with people who go around the community preying on the sick and extracting their money through this type of swindle.

Unlicensed "Doctor" Fined $300.00

State of Minnesota *vs.* Knapp

On August 18, 1930, J. Knapp, 65 years old, of 522 South Eighth Street, Minneapolis, and 7 E. Tenth Street, St. Paul, was fined $300 or three months in the Workhouse by the Honorable J. C. Michael, Judge of the District Court of Saint Paul, for practicing medicine without a Basic Science Certificate. Defendant paid the fine.

Knapp had been posing as a specialist in rheumatism, nervousness and stomach disorders. He claimed to have a cure for all stomach ailments except cancer. He has been operating in St. Paul and Minneapolis over a period of the last five or six years. The defendant is a man with no medical education and has followed the barber and painting trades during his lifetime.

The case was handled by Mr. Brist on behalf of the Minnesota State Board of Medical Examiners and splendid coöperation was received from C. D. O'Brien, Jr., County Attorney of Ramsey County, in effecting a speedy disposal of this case.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 10:15 o'clock every Wednesday morning over station WCCO, Minneapolis and St. Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of October will be as follows:

October 1st—Finish the Job
October 8th—Cancer of the Rectum
October 15th—Father of Medicine
October 22nd—Food Fads
October 29th—Finger Infections

INTER-STATE POST-GRADUATE ASSOCIATION OF NORTH AMERICA

Minneapolis Auditorium

October 20 to 24, inclusive

Officers of the Association

President—Dr. William D. Haggard, Nashville, Tennessee

Presidents of Clinics—Dr. William J. Mayo, Rochester, Minnesota; Dr. Charles H. Mayo, Rochester, Minnesota

President-Elect—Henry A. Christian, Boston, Massachusetts

Managing Director—Dr. William B. Peck, Freeport, Illinois

Executive Secretary and Director of Exhibits—Dr. Edwin Henes, Jr., Milwaukee, Wisconsin.

Treasurer and Director of Foundation Fund—Dr. Henry G. Langworthy, Dubuque, Iowa

Speaker of the Assembly—Dr. George V. I. Brown, Milwaukee, Wisconsin

Chairman of Program Committee—Dr. George W. Crile, Cleveland, Ohio

The meetings will be held under the supervision of the Hennepin County Medical Society, Dr. E. L. Gardner, president, and Dr. E. W. Hansen, Secretary.

The Executive Committee consists of Dr. N. O. Pearce, general chairman, and Dr. J. C. Litzenberg and Dr. James S. Reynolds, general vice-chairmen.

The following local committee chairmen have been appointed:

Dr. F. A. Erb—Auditorium
Dr. A. T. Mann—Banquet
Dr. Claude J. Ehrenberg—Entertainment
Dr. J. S. Reynolds—Finance
Dr. Angus W. Morrison—Foreign Guests
Dr. W. A. Fansler—Hotels
Dr. R. O. Beard—Publicity

(Continued on Page 727)

A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION

For Better Newspaper Medicine

Dr. Gilbert Seaman of Milwaukee Suggests a Cure for Editorial "Double Pneumonia"

Most physicians concede, nowadays, that they have a definite obligation to educate the public in matters of personal hygiene, public health and preventive medicine.

Official agencies for the dissemination of authoritative information in these matters are growing. They are the accredited organs of organized medical societies and no one doubts that the good they are capable of doing is incalculable both for the lay public and the doctor.

But the doctor must not consider that his public obligations end with these services, in the opinion of Gilbert Seaman of Milwaukee.

Newspapers still deal in "double pneumonia" and deaths from indiscriminate "ptomaine poisoning," to mention only minor medical delinquencies. They are still occasionally given to distorting medical facts and distressing individual physicians for the sake of human interest "features."

Dr. Seaman urges a better coöperation between the doctor and the editor in a pertinent and interesting paper called "The Doctor Looks at Journalism," read in Milwaukee recently. The editor, and, through him, the public, is entitled to the real facts of scientific medicine.

"Whether or not the doctor is practicing in private or public hospitals or in private practise, he is a servant of the public and should take an active interest in the dissemination of accurate medical information," says Dr. Seaman.

"The whole scheme of preventive medicine depends upon education of the public. You cannot drive people to protect themselves against disease. They must have accurate information on medical matters even when these matters are incidental to the day's news. The newspaper's business is to furnish news in which the public is interested, and this the newspaper man knows how to do. But it is not necessary to distort medical news to do it.

"There must be a better understanding between the press and the medical profession. Ready sources of medical information should be provided by medical societies, colleges and libraries.

"Too often the personality of the doctor and not the essential medical facts are the theme of a newspaper story. The press is not entirely guiltless in arbitrarily putting the wrong emphasis on its medical news. But it is a fact that far too often this tendency to distort and play upon the human interest element is due to complete ignorance of the medical facts, coupled with complete inability to get at those facts.

"A proper well established channel of information between the editor and local medical profession would do a great deal to avoid such things. It would operate, also, to prevent the publication of much news that is unsuitable from the standpoint of the medical profession."

(Continued from Page 725)

Dr. C. B. Wright—Reception
Dr. O. S. Wyatt—Registration
Drs. W. A. O'Brien and E. F. Robb—Scientific Exhibits
Dr. E. C. Robitshek—Transportation
Dr. James M. Hayes—Clinics
Mrs. Emil Geist—Ladies

The International Medical Assembly is the opportunity of a week's intensive graduate study in Medicine, presented by the Inter-State Postgraduate Medical Association of North America. It is to be held this year from October 20th to 24th, inclusive, at the Minneapolis Auditorium.

The Association is unique, among medical organizations, in respect of the fact that aside from a few life members, it has no regular membership. Under a registration fee of $5.00 any physician in good and regular standing, in the American and Canadian Medical Associations, and their component parts, is a member of the Assembly, for the purposes of this meeting. He does not become, thereby, a member of the Association. Life-members are exempt from the registration fee. They will present their life membership cards. The courtesies of the Assembly are extended to Army, Navy, Marine Corps and Veterans Bureau officers, and to full-time officers and officials of local, State and National Public Health Services, upon presentation of their credentials. All physicians should come prepared to show their County, State or National Society Membership cards.

A registration bureau will be set up at the Hotel Nicollet, on Sunday morning, October 19, and local physicians of City, County or State are requested to register in advance of the meeting. Local committeemen are asked, also, to register in advance of the opening of the Assembly.

The Main Registration Bureau will be placed at one end of the Exhibit Hall on the lower level of the Auditorium. It will open on Monday morning, October 20, 1930, in season for the first session of the assembly. On and after this date all registration will be conducted in this Main Registration Bureau. Ladies will be asked to register at a special bureau and distinctive badges will be issued to the men and the women.

All physicians must register.

The plan of program for the International Medical Assembly is as unique as its membership plan. The opening session of the Scientific Program will begin promptly at 7:30 o'clock, Monday morning, October 20, 1930. The organization is essentially a hard-working one. This early morning hour will mark the rising bell of business for the Assembly each day. The morning hours of the entire meeting will be occupied by a succession of diagnostic clinics. There will be an intermission at noon, presumably for luncheon, but it will be immediately followed, at an unstated hour, by two or three more diagnostic clinics.

The afternoon scssions will be devoted to a series of addresses. Both morning and afternoon meetings will be broken by intermission to permit of visits to the Technical and Scientific Exhibits. Evening sessions on each day, excepting Friday, October 24th, will be held, at which a number of addresses will be given.

In the four days' meeting, 38 diagnostic clinics, 84 addresses and 118 exhibits will be presented. The program could hardly be more compact, while practically every branch of medicine and surgery is covered by its papers.

It is the aim of the Inter-State Postgraduate Medical Association, in its annual International Assemblies, to present to the Medical Profession every well-validated advance in medical science and every approved product of research related to it.

It devotes itself exclusively to post-graduate medical education. It exercises no political influence. It enters into no legislative activities.

Every physician of the Twin Cities and of the state at large is invited to share the outstanding values of these meetings of the International Medical Assembly. Set aside this week for a visit to Minneapolis and spend it at the Auditorium!

ANNOUNCEMENT EXTRAORDINARY

One of the outstanding events of the coming Inter-State Post Graduate Medical Association meeting in Minneapolis will be the banquet at the Nicollet Hotel. Friday evening, October 24. On the speakers' program will be many distinguished guests, both lay and medical, some of whom have come a great distance from different parts of the world.

The banquet at the Saint Paul meeting of this organization some years ago has often been commented upon as having been the best in the history of the Association and it is naturally desirable that the Northwest should covet such distinction in an equally or even more successful occasion in Minneapolis. In the promotion of such success the physicians of the entire Northwest are earnestly requested to assist.

Physicians may bring their wives and it is expected that some interested laymen will want to attend. The available seating being limited, those desiring to attend are requested to make reservations early by sending a check for cover charges at $5.00 a plate to Dr. A. E. Hedback, chairman of the Ticket Committee, care of Hennepin County Medical Society, Medical Arts Building, Minneapolis.

SOUTHERN MINNESOTA MEDICAL ASSOCIATION

At the annual meeting of the Southern Minnesota Medical Association held in Mankato August 25, the following officers were elected:

Dr. J. T. Schlesselman, Mankato, president
Dr. I. W. Steiner, Winona, first vice-president
Dr. P. F. Holm, Wells, second vice-president
Dr. M. C. Piper, Rochester, secretary-treasurer

One hundred and fifty-one physicians registered at the meeting and fifty-three new members were taken into the Association.

Dr. R. T. Westman of Cloquet was awarded the medal for the medical student at the University show-

ing the highest degree of proficiency in clinical fields of medicine and surgery during junior and senior years.

Dr. L. G. Rigler of Minneapolis was awarded the society medal for the best display in the scientific exhibit at the State Medical Meeting at Duluth in July.

AMERICAN PUBLIC HEALTH ASSOCIATION

The 59th annual meeting of the American Public Health Association will be held in Fort Worth, Texas, October 27 to 30.

Public health workers of Canada, Mexico and Cuba, as well as those of the United States, will contribute to the extensive program arranged. Among the speakers will be the president of the Association, Dr. A. J. Chesley, of Minnesota, and the president-elect, Dr. Hugh S. Cummings, Surgeon General of the Public Health Service.

Among interesting features arranged in connection with the meeting are a Texas barbecue and a rodeo. Special trips to Austin, San Antonio and to Mexico City have been arranged. Further details may be obtained from Homer N. Calver, Executive Secretary of the Association, at 370 Seventh Avenue, New York City.

NORTHERN MINNESOTA MEDICAL ASSOCIATION

Dr. B. S. Adams of Hibbing was elected president of the Northern Minnesota Medical Association at the closing session of its annual convention at Moorhead Minnesota, September 20. Other officers chosen, in addition to Dr. Adams, who succeeds Dr. H. C. Cooney of Princeton, are Dr. G. S. Wattam of Warren, vice president, and Dr. O. O. Larson of Detroit Lakes, secretary-treasurer.

Hibbing was chosen as the convention city for 1931

SCOTT-CARVER COUNTY MEDICAL SOCIETY

On August 12, 1930, the Scott-Carver County Medical Society met at Dr. F. Buck's cottage on Prior Lake. Dr. Reuben Johnson was the principal speaker and gave an address on "Serum Reactions." It was decided to hold the next meeting at Waconia in September, in charge of Dr. H. D. Nagel.

B. H. Simons, *Secretary.*

VIOSTEROL OR IRRADIATION

If rickets is the disorder that is to be cured or averted, both cod liver oil and irradiated ergosterol, the latter now available as viosterol in oil 100 D, act as specifics; so that irradiation with artificial light sources is not essential though its effectiveness to accomplish the same ends deserves emphasis. Viosterol also serves to promote the proper metabolism of calcium and phosphorus in other disorders. On the other hand, irradiation with ultraviolet rays doubtless produces a variety of physiologic effects about which we are still largely uninformed. (Jour. A.M.A., February 22, 1930, p. 580.)

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

EYE, EAR, NOSE AND THROAT

ABSCESS OF THE BRAIN FROM THE STANDPOINT OF THE OPHTHALMOLOGIST: Wm. L. Benedict (Trans. of the Amer. Acad. of Oph. and Otolaryng., 1929, p. 52). The history of the onset of the pathologic process is very important as none of the ocular signs or symptoms are pathognomonic. Even then we must also consider extradural abscess, osteomyelitis of the skull, and tumor of the dura with softening or hemorrhage, as these are conditions which may occur concomitant with diseases of the sinuses or mastoid.

The development of brain abscess may be divided into three stages: (1) the initiatory stage, characterized by severe pain in the head, vomiting, rigor and fever; (2) the second stage, characterized by pain in the head (which can be elicited only by percussion), slow cerebration, want of sustained attention, apyrexia, slow pulse, paralysis and optic neuritis; (3) the third stage, wherein there is leakage of pus into the membranes or ventricles, accompanied by fever, convulsions

and coma; or else there is complete encapsulation of the abscess, which may become quiescent for a long period and may finally become absorbed, in some cases without surgical interference.

The most common sign found is choked disc, occurring in about one-third of the cases. While the abscess is developing, the choked disc fluctuates in appearance, becoming stationary when the abscess becomes encapsulated. At this time surgery should be undertaken. Choked disc usually appears bilaterally, but the edema on the two sides is frequently of different degree. This does not greatly help in localization as it may be advancing on one side and receding on the other. In certain lesions of the frontal lobe, direct pressure may cause atrophy with or without previous choked disc.

Peripheral vision changes have the same significance in brain abscess as they have in brain tumor. The most characteristic alteration is hemianopsia and is dependent on the site of the lesion. Homonymous hemianopia appears in temporal lobe abscesses if they are subcortical and affect the optic radiations. It is also found in lesions of the occipital lobe. Characteristic field changes are rare in frontal lobe lesions.

Nystagmus, which may be horizontal, vertical or rotatory, is particularly common in cerebellar abscesses.

Signs of partial paralysis of the third nerve are most often associated with abscess of the temporal lobe and nearly always with choked discs. Paralysis of the sixth nerve has no localizing value.

L. G. Flanagan, M.D.

PEDIATRICS

THE USE OF PHENOBARBITAL IN INFANT FEEDING: E. J. Barnett, M.D., Spokane, Wash. (Arch. of Ped., Vol. XLVII, No. 7, July, 1930). Phenobarbital in infant feeding is much more valuable than is ordinarily known. The use of phenobarbital has become almost routine with us, not only in cases of pyloric stenosis and pylorospasm, but also in infants suffering with severe colic.

The "vomiting center" in the brain must be involved in pyloric stenosis, otherwise it would be difficult to explain why phenobarbital is apparently so specific for the control of the projectile vomiting. The "vomiting center" in cases of pyloric stenosis must become more sensitive from gastric irritation of the vagus or sympathetic nerve endings, and vomiting results.

The extensive use of atropine in pyloric stenosis and colic has usually been justified on its value as an antispasmodic. It is quite possible that atropine has the same effect as phenobarbital on control of vomiting by its impairment of the afferent emetic impulses along the vagus to the "vomiting center" in the brain. The advantage of phenobarbital over atropine is the absence of alarming febrile reactions as is so often observed with the use of atropine alone.

It has been emphasized that all the barbital derivatives exert their effects most markedly when the patient is kept in quiet surroundings away from nervous excitement.

Phenobarbital is available in one quarter grain tablets. We have found that a tablet of this size, crushed, and given before or in each feeding, is the largest dose necessary to control the most obstinate or severe curable case of colic or vomiting. The average case requires only one-eighth of a grain dose. We have made a practice of combining one drop of a fresh 1:1000 solution of atropine sulphate with each dose of the phenobarbital. We have not observed cases of "atropine fever," when the two drugs have been combined.

R. N. Andrews, M.D.

TREATMENT OF INFANTILE ECZEMA: Harry D. Grossman, M.D., Chicago (Arch. of Ped., August, 1930, Vol. XLVII, No. 8). The treatment of infantile eczema is entirely empirical today, despite the large amount of work which has been done attempting to show that this skin disease is due to the various factors in the diet of infants, such as proteins, fats, carbohydrates, and fruit juices.

Except in very rare instances, removal of butter-fat, excess sugars, orange juice and food proteins produces no relief from either the subjective symptoms or the objective findings, unless local treatment is used at the same time.

Infantile eczema responds, usually, very nicely and fairly quickly, to crude coal tar used in a suitable ointment base, so that it seems rather sorrowful that it is not used more extensively by the medical practitioner generally, and the dermatologist specifically.

In severe cases, characterized by marked redness with much weeping and marked crusting accompanied by severe itching, the author usually starts with the following ointment applied twice daily, morning and night:

Crude coal tar	6.0
Zinc Oxide	....
Powdered starch	4.0
Petrolatum q. s. ad.	30.0

The ointment is removed in the morning with sweet oil or olive oil, and then new ointment is re-applied.

The stage in which the weeping and crusting are absent, and in which the skin is red and rough, may be characterized as of moderate severity, and for this the author reduces the strength of the ointment to ten per cent crude coal tar, using the same base.

The redness and roughness of the skin disappear more slowly than do the weeping and crusting, but usually in 7 to 14 days on this second salve the skin is smooth and may be almost normal in color or a bit pinker than normal. As the skin improves, the strength of the ointment should be again reduced, this time to five per cent, and applied twice daily for seven to ten days even though the skin looks normal.

Any tendency to recurrence of the eczema is countered by an application of the five per cent ointment.

R. N. Andrews, M.D.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

TEXT-BOOK OF HISTOLOGY. Harvey Ernest Jordan, A.M., Ph.D. Professor of Histology and Embryology, University of Virginia. 857 pages. Illus. New York: D. Appleton & Company, 1930.

NERVOUS INDIGESTION. Walter C. Alvarez, M.D., Associate Professor of Medicine, University of Minnesota (The Mayo Foundation). 297 pages. Price, $3.75. New York: Paul B. Hoeber, Inc., 1930.

COMPOSITE INDEX AND CUMULATIVE SUPPLEMENT (Vol. XXI, Clinical Pediatrics). 385 pages. New York: D. Appleton & Company, 1930.

DISEASES OF THE GENITO-URINARY SYSTEM IN INFANCY AND CHILDHOOD. Henry F. Helmholz, M.D., Professor of Pediatrics, University of Minnesota (The Mayo Foundation), etc.; and Samuel Amberg, M.D., Associate Professor of Pediatrics, University of Minnesota (Thc Mayo Foundation), etc. 239 pages. Illus. New York: D. Appleton & Company, 1930.

WANTED—Position as physician's office assistant or clinic assistant, by registered nurse with several years' experience. Address D-103, care MINNESOTA MEDICINE.

POSITION WANTED—As assistant to hospital superintendent. Experienced. Can furnish excellent references. Address D-104, care MINNESOTA MEDICINE.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

PHYSICIAN'S OFFICE FOR RENT—Best location Midway district, corner Thomas and Hamline, Saint Paul. Rent $25.00 a month. Inquire at dentist's office.

FOR SALE—Practice in southwestern Minnesota. Good town in best farming part of state, nearest doctor nine miles. Best reasons for selling and all asked is to take the home. Address D-100, care MINNESOTA MEDICINE.

WANTED—First class eye, ear, nose and throat specialist to become associated with a group of physicians in Minneapolis. Overhead expenses on percentage basis. State age and place of special training. Address D-99, care MINNESOTA MEDICINE.

FOR SALE—Wonderful opportunity for surgeon. Eighteen room hospital. Operating room. Modern. Good practice, rich country. Building cost $21,000. priced $6,000. Small cash payment. Will send photo. Address Wallace King, Waverly, Minnesota.

POSITION WANTED—Technician with three years' experience in hospital and clinical laboratories desires location. Address D-98, c/o MINNESOTA MEDICINE.

FOR SALE—Complete office, reception and examining room equipment. Office for rent, Lowry Medical Arts Building, $30 per month. Call Dale 7748.

WANTED—Position as assistant, partner or location for general practice. Minnesota graduate; one year interneship General Hospital, Minneapolis; two years assistantship in general practice; one year's surgical residency. Good references. Address D-101, care MINNESOTA MEDICINE.

LOCUM TENENS DESIRED by well qualified physician. Licensed in Minnesota. Available at once. Address D-102, care MINNESOTA MEDICINE.

MINNESOTA STATE MEDICAL ASSOCIATION

SIXTY-SECOND ANNUAL SESSION

DULUTH, MINNESOTA

PROCEEDINGS OF THE HOUSE OF DELEGATES

FIRST MEETING, MONDAY AFTERNOON, JULY 14, 1930

The meeting of the House of Delegates of the Minnesota State Medical Association, held in the English Room of the Hotel Duluth, Duluth, Minnesota, convened at 2:10 o'clock, Dr. S. H. Boyer, President of the Association, presiding.

PRESIDENT BOYER: The meeting of the House of Delegates will come to order.

The Chair has appointed a Credentials Committee consisting of: Dr. E. S. Boleyn of Stillwater, Dr. S. H. Baxter of Minneapolis, Dr. A. W. Adson of Rochester, and we are ready to listen to its report. Is the committee ready to report?

DR. BOLEYN (Stillwater): There are fifty-one accredited members present.

The following delegates were present:

Blue Earth County—J. T. Schlesselman, Mankato; Blue Earth Valley—Not represented; Camp Release District—M. S. Nelson, Granite Falls; Central Minnesota—H. C. Cooney, Princeton; Chisago-Pine County—F. F. Callahan, Pokegama; Clay-Becker—R. E. Scott, Detroit Lakes; Dodge County Medical Society—D. E. Affeldt, Kasson; Freeborn County—W. L. Palmer, Albert Lea; Goodhue County—Not represented; Hennepin County—W. A. Fansler, E. K. Green, W. A. Jones, J. A. Myers, C. B. Wright, S. H. Baxter, N. O. Pearce, F. A. Erb, Ivar Sivertsen, H. B. Hannah, Donald McCarthy; Houston-Fillmore County—Not represented; Kandiyohi-Swift—C. L. Scofield, Benson; Lyon-Lincoln—Not represented; McLeod County—Not represented; Meeker County—A. W. Robertson, Litchfield; Mower County—C. L. Sheedy, Austin; Nicollet-Le Sueur—Not represented; Olmsted County—Waltman Waters, F. A. Willius, A. W. Adson, W. F. Braasch, L. W. Pollock, P. A. O'Leary, H. M. Conner; Park Region District—A. D. Haskell, Alexandria; Ramsey County—E. M. Hammes, H. J. Rothschild, O. W. Holcomb, Carl B. Drake, V. P. Hauser, F. H. Neher; Redwood-Brown—George B. Weiser, New Ulm; Red River Valley—H. M. Blegen, Warren; O. E. Locken, Crookston; Rice County—A. M. Hanson, Faribault; St. Louis County—B. S. Adams, Hibbing; J. R. Manley, Duluth, F. H. Magney, Duluth, C. L. Haney, Duluth; Scott-Carver—W. F. Maertz, New Prague; Southwestern Minnesota—Wm. A. Piper, Mountain Lake, F. M. Manson, Worthington; Stearns-Benton—C. B. Lewis, St. Cloud; Steele County—A. B. Stewart, Owatonna; Upper Mississippi—J. A. Thabes, Brainerd, F. F. Kumm, Wadena; Wabasha County—W. H. Replogle, Wabasha; Waseca County—B. I. Saliterman, Janesville; Washington County—E. S. Boleyn, Stillwater; Watonwan County—B. H. Haynes, Butterfield; West Central Minnesota—Not represented; Winona County—C. P. Robbins, Winona; Wright County—A. M. Ridgway, Annandale.

PRESIDENT BOYER: We are now ready to consider the minutes of the last meeting. The minutes are rather long and have been published in MINNESOTA MEDICINE, so the reading of them may be dispensed with unless you desire otherwise. What shall we do with the minutes of the last meeting?

A motion was made and seconded that the reading of the minutes of the last meeting be dispensed with and the minutes accepted, which motion, being put to a vote, was carried.

PRESIDENT BOYER: The first report this afternoon is that of the President of the Council, Dr. H. M. Workman, of Tracy.

Dr. Workman read the report of the President of the Council.

MEETING OF THE COUNCIL

A meeting of the Council of the Minnesota State Medical Association was held on Sunday, July 13th, 1930, at 6:30 P. M. at the Hotel Duluth, Duluth, Minnesota, Dr. Workman, President of the Council, presiding.

The following were present: H. M. Workman, W. H. Condit, W. A. Coventry, M. S. Henderson, F. A. Dodge, G. S. Wattam, W. W. Will, F. J. Savage, L. Sogge, S. H. Boyer, A. G. Schulze, E. A. Meyerding.

The minutes of the meeting of the Council on January 10 were read and approved.

Dr. Schulze read the Treasurer's report for the year 1929.

Dr. Savage, chairman of the Finance Committee, read the report of the Fiscal Agency Account, with a statement of property. The report was accepted and placed on file.

The second quarterly report from MINNESOTA MEDICINE was read and approved. The profit for MINNESOTA MEDICINE for 1929 was $1,081.52.

Dr. Pearce, Chairman of the Committee on Hospitals and Medical Education, appeared before the Council telling of the plans of his committee for the remainder of the year. Motion made by Dr. Coventry, seconded, and carried that the budget of the Committee on Hospitals and Medical Education be increased $100 for 1930.

A report of the membership of the Association was read. There are at the present time 2,035 paid members.

Motion made by Dr. Savage, seconded, and carried that Dr. Thomas G. Lee of Minneapolis be recom-

mended to the House of Delegates for Associate Membership in the Minnesota State Medical Association.

Motion made by Dr. Schulze, seconded, and carried that Dr. Donald Smelzer, formerly of St. Paul, and now residing in Pennsylvania, be recommended to the House of Delegates for Associate Membership in the Minnesota State Medical Association.

Motion made by Dr. Savage, seconded, and carried that Dr. John F. Noble be recommended to the House of Delegates for Associate Membership in the Minnesota State Medical Association.

A list of the Affiliate Fellows elected at the Detroit Session of the American Medical Association was read.

Motion made by Dr. Sogge, seconded, and carried that the Council recommend to the House of Delegates the granting of a charter to form the Dakota County Medical Society as requested in the petition presented.

Motion made by Dr. Boyer, seconded, and carried that a letter be written to the secretary of the Minnesota Funeral Directors Association calling his attention to the law that makes it compulsory for the physician to sign a death certificate and suggesting that he call this to the attention of the physician when asking him to sign such a certificate.

The reports of the Councilors were received and placed on file.

Dr. Boyer's letter to Mrs. Mendenhall, president of the Parents-Teachers Association, was read. The Attorney General's opinion *re* pre-school examination was read. It was suggested that these letters and Mrs. Mendenhall's reply to Dr. Boyer be read before the House of Delegates.

The Minnesota State Medical Association did not have a representative at the U. S. Pharmacopeia Meeting as Dr. Hirschfelder could represent only one organization, the University.

Motion made by Dr. Henderson, seconded, and carried that Drs. H. M. Johnson and W. F. Braasch be recommended to the House of Delegates for re-election as delegates to the American Medical Association for a period of two years beginning January 1, 1931.

Motion made by Dr. Coventry, seconded, and carried that Drs. B. S. Adams and O. J. Hagen be recommended to the House of Delegates for re-election as alternate delegates to the American Medical Association for a period of two years beginning January 1, 1931.

The reports to be presented to the House of Delegates were discussed:

Dr. Coventry was appointed a committee of one to draw up an amendment to the By-Laws to be presented to the House of Delegates abolishing the Committee on Necrology. The Necrologist's report will become one of the duties of the Historical Committee.

Motion made by Dr. Boyer, seconded, and carried that the name of Robert Emmett Farr be commended to the Nobel Prize Committee for consideration in reference to his original work in local anesthesia, in particular that of splanchnic nerve anesthesia.

Motion made by Dr. Condit, seconded, and carried that the Secretary's salary be increased $100 a month.

The meeting adjourned at 12:35 A. M.

President Boyer: Gentlemen, what will we do with the report of the President of the Council?

A motion was made and seconded that the report be accepted, which motion was carried.

Dr. Myers (Minneapolis): I move that the House of Delegates extend to the Council, and to Dr. Workman especially, a vote of thanks.

This was done.

President Boyer: Gentlemen, whether you like it or not, this profession is no longer an austere and closed cloister body. We have no business to think of ourselves as being set apart with a special knowledge which entitles us to special consideration. You have to take part in the things that are going on. You must enter into the mode of the world today, and you must expect that there will be continued expense in the maintenance of your organization and the carrying on of the work involved, and you must expect that from time to time there will be increases in the expenses, and you must expect that from time to time the expenses will grow less, dependent upon the conditions that exist.

I wish to introduce a guest that we have with us today, the Secretary of the American Medical Association. I take pleasure in introducing to you Dr. Olin West. (Applause.)

Dr. West (Chicago): Mr. Chairman, and gentlemen of the House of Delegates: I sincerely appreciate this courtesy extended to me. I have no desire whatever to impose upon your time. I know you have many things to deal with, and I don't want to interfere with your program. I listened with real delight to the report of the Council submitted by its honored Chairman. I recall very distinctly my attendance at a meeting of the Minnesota Medical Association some six or eight years ago, and it is perfectly evident to me, who am interested, of course, in the activities of all state medical associations that are constituent units of the American Medical Association, that the Minnesota State Medical Association has made notable progress, and I am convinced from the comments I have heard expressed here upon the interest your representatives take in the House of Delegates of the American Medical Association, from the improvement that has been made in its official organ and from the positions that are being taken by members of this Association, that the Minnesota State Medical Association has set its eye to the pinnacle and it is going to continue to progress. I am very grateful indeed to you, Mr. Chairman, for your courtesy, and am glad to have the opportunity of being here today. (Applause.)

President Boyer: We have the honor, gentlemen, of having as a guest today, Mr. W. J. Burns, the Executive Secretary of the Wayne County, Michigan, Society. Wayne County is that district in which the small town of Detroit has its being. I would like to call upon Mr. Burns for a few remarks. (Applause.)

Mr. Burns (Detroit): I think my remarks can be epitomized in this little note I received before I left Detroit from Dr. Warnshuis. He says:

"Dear Red: When you go to Duluth you are commissioned by me to extend to the Minnesota doctors

Michigan's fraternal greetings and good wishes. We join with them in a concerted, sustained activity to convey the truths and principles of modern scientific medicine to the people in order to enhance their health welfare. We seek to provide our members with opportunities for post-graduate work in order that their service may reflect the knowledge of today. We strive to defeat the machinations of the quack and of those who along political lines seek to lower the qualifications for practice. In these activities we note with favor the achievements of the Minnesota profession and bid them to continue their militant attitude. Such achievements are an inspiration to all who are concerned with an attainment of the ideals of medicine.

Sincerely,

F. C. WARNSHUIS."

That is all I have to say, except that I want to thank you for the opportunity of making these few remarks, and I want to ask you to come back to Detroit for another American Medical Association meeting if Dr. West decides it will be there very soon. (Applause.)

PRESIDENT BOYER: I am sure we all appreciate the remarks of Mr. Burns.

Next is the report of the President of the Association.

PRESIDENT'S REPORT TO THE HOUSE OF DELEGATES

Gentlemen:

The work done so far this year has been largely in the field of medical organization, with occasional visits to other medical organizations in a representative capacity.

There were five meetings of the program committee, all of which were attended by the president. At the meeting in February of the American College of Physicians an address of welcome was extended in the interest of the State Association. About the same time a meeting was called of the chairmen and members of the various committees with the idea of correlating various committee work and establishing an interest on the part of the various committee members in the work assigned to them. The day following this meeting there was a special meeting of the legislative committee.

On the 5th of April there was a conference with the executive committee of the Hennepin County Medical Society to consider financial matters. In April the meeting of the Ramsey County Medical Society was attended also. The special purpose in this case was a discussion of State Society dues. It may be well to state at this point that almost uniformly through the state the present dues meet with approval on the part of the component societies and members.

The spring meeting of the Upper Mississippi Valley Medical Association was attended at the request of its membership. The society desired information concerning various state activities. Organization meetings were attended at Willmar, Brainerd, Winona, Austin and Albert Lea.

An address was given to the Iowa State Society meeting at Marshalltown in May, in relation to medical legislation as it obtains in Minnesota.

Aside from attending the reception tendered by the Mayo Clinic to Dr. E. Starr Judd, president-elect of the American Medical Association, the work has been of a routine nature.

PRESIDENT BOYER: The report of the Secretary is in the hands of the Reference Committee. We will hear that report later. We will proceed now with the report of the delegates to the American Medical Association.

DR. BRAASCH (Rochester): As I recall it, the delegates sort of divided the burden among themselves. I am supposed to give a résumé of the meeting of 1929 which was held in Portland. I will not detain you long with the report, as it is already a matter of past history.

DELEGATE'S REPORT OF PROCEEDINGS OF THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION DURING THE MEETING OF 1929

It is unfortunate that the best way we have at our command of informing the members of the Association as to the activities of the various officers and committees of the American Medical Association and as to the proceedings in the House of Delegates is through the annual report of the State delegate to the local House. It is true that these proceedings and committee reports are published in the Journal of the American Medical Association, but they are usually published in one or two issues, in fine print and placed in the back of the Journal, so that very few of the members take the time and trouble to read the rather voluminous reports. It would be much better if a synopsis of the more important activities were made, so written that it would appeal to the average member of our Association, and printed in a separate form such as in the Monthly Bulletin, which would insure a widespread circulation. It would obviously be for the best interests of our Association to create an intelligent opinion among its members. In this way only is it possible for the House of Delegates and the officers to obtain the best results in the conduct of its affairs.

As I said before, the inadequacy of a report of this kind is apparent. However, I will content myself with a brief summary of the more important activities, some of which I hope will make some appeal to you.

The meeting of last year, which was held in Portland, had an unusually small registration, the total being but 3,061, the largest number being from the western coast and the middle west. There were but 200 men registering from the east, showing how provincial the easterner really is and furthermore, how much farther it is from the Atlantic to the Pacific coast than it is from the Pacific to the Atlantic coast.

In his address President Thayer discussed a variety of subjects, including the work of the Council on Medical Education and Hospitals, and referred to the desirability of carrying on the work of the Index Catalog in the Surgeon General's Office. He also referred to the legislation which interfered with the preroga-

tives of the physician in regard to prescription writing and as a result aroused a controversy in the press between the clergy and himself. President Thayer, however, was supported in his stand, which was quite logical, by the House.

President-elect Harris in his address referred to the high cost of medical care and urged that the subject should receive the serious consideration of the medical profession; that the solution was in their hands rather than in the hands of the layman.

A resolution to the effect that expenses of the delegates be paid by the American Medical Association failed to pass.

Attention was called to the fact that there were a number of hospitals that were unethical in their methods of advertising and that some 400 hospitals have already been omitted from the list of accredited hospitals on account of such unethical practices.

Plans for increasing the size of the headquarters and enlarging the opportunities of the Association received favorable action.

It was proposed that all papers read before the Scientific Session of the Association be published, but the resolution was defeated.

A resolution favoring the establishment of a Home for Aged Physicians was defeated, because it was thought that it was more a matter for individual state societies to decide rather than the national organization.

The value of diagnostic clinics and clinical lectures in the program was emphasized.

The clause in the constitution referring to the Principles of Medical Ethics in Section 3, Art. VI, Chapter II, was altered so as to read as follows: "When a patient is referred by one physician to another for consultation or for treatment, whether the physician in charge accompanies the patient or not, it is unethical to give or to receive a commission by whatever term it may be called or under any guise or pretext whatsoever."

Doubtless you will recall that in the 1928 meeting you charged your delegates to call attention and to criticize the action of the Red Cross in authorizing its nurses to nurse for those other than regular practitioners. This was done and a vote of approval given.

The raising of the price of the Journal of the American Medical Association from $6 to $8 was authorized.

Four cities extended invitations to the American Medical Association as the next meeting place, namely Detroit, Philadelphia, Atlantic City and Memphis, Detroit being selected.

In order to obtain an adequate idea of the scope of the work which is being done by the various officers and committees of the Association it would be necessary to read detailed reports. Most important among them was that of the Board of Trustees. The scope of the work of this most important body is exceedingly wide and a perusal of the report would well repay one for the trouble.

In their report the Board of Trustees urged that the circulation of Hygeia be increased, and called attention to the fact that it is particularly applicable to the office table of most physicians. They called attention to the good work of the Women's Auxiliary in extending the circulation of Hygeia. They also mentioned the increase in the use of the Association library in the lending of periodicals.

Attention was called to the work of the Council on Pharmacy and Chemistry and it was stated that as a result of the untiring and unselfish service of those who compose the Council, the leading representatives of the American Pharmaceutical industry have relegated the drug mixture to the background, and by the employment of competent scientific staffs are doing an excellent work in the development of new and better drugs. From year to year appreciation of the Council's work has been increasing and today this body is recognized as an authority on drugs and drug therapy alike by the medical profession and by the pharmaceutical industry. It would seem that the reports of the Council on Pharmacy and Chemistry should have a wider circulation than at present. Few of us realize how many activities this Council is engaged in. Among the most interesting is the Therapeutic Research Committee, which has charge of subsidizing research problems in various lines of therapy. It is also true that intelligent investigation is carried on in the Chemical Laboratory. The work of the Council on Physical Therapy was also commented upon and commended.

No doubt few of us also realize the scope of the work of the Bureau of Investigation which answers thousands of letters of inquiry of various kinds during the year.

Probably the most interesting report from the Bureau of Legal Medicine and Legislation was that regarding the progress made in the matter of income taxes on the earnings of physicians. The attitude of the House of Delegates toward the Sheppard-Towner Maternity Act was reasserted as being inimical to its continuation. On the subject of Medical Defense it was stated that what was needed was organized effort by medical defense committees maintained by our state medical associations to prevent claims based on alleged malpractice from arising. This function of the medical defense committee seems to be more important than its function of assisting in the settlement of claims after they have arisen.

All of these committee reports and the various resolutions offered were referred to reference committees of the House of Delegates for their consideration and criticism. Voicing their approval or suggesting alteration, these reports were referred to the House for further consideration and approval. Every opportunity is given the members for expression of individual opinion. It is remarkable how the majority opinion is frequently registered with no uncertainty and usually with logical intelligence. The smoothness with which the large amount of business is taken care of is largely due to the good judgment and keen intelligence of the Speaker of the House, Doctor Warnshuis.

PRESIDENT BOYER: We would like to hear from Dr. Wright, another of the delegates.

DR. WRIGHT (Minneapolis): I don't like to take up

too much time. The thing, I think, that impresses you in the House of Delegates is the efficiency and speed with which things are transacted. The reports, as a rule, are very brief and very thorough and comprehensive. During the interim they thresh out these reports and anyone who wants to defend his report can do it there. But it is a very impressive legislative body, and it seems to me that there was more zip and energy and keenness exhibited in the House of Delegates in discussing our many problems than there ever was before.

One of the outstanding things we had to deal with was the question of the new legislation regarding veterans of the World War. Mr. Hoover wired for our opinion on the question, and he got it in a very convincing way. It shows how our Association has risen in the minds of those in the legislative halls when they will wire for our opinion. There is no question but what the Chicago office is on its toes. The outstanding thing, I think, this year was the new Economics Bureau. It was introduced by California organizing an Economics Committee to take up all these questions relating to the economy question of the profession and try to devise some, solution, or at least to have some point of view in our attitude with the public on many of these questions. That was thoroughly discussed.

The question of the veterans' legislation, apparently no solution was offered and no method of solution could solve it. This question of constant expense and care of soldiers who have become ill since the war is a very serious matter. I was talking to some of the Congressmen at Washington and they said it is going to cost this country a hundred billion dollars to take care of them. One question which Congressman Andresen was very anxious for me to answer was this: Is it true that these men can not be taken care of as well by civil doctors in civil hospitals as they can in Government Hospitals and by Government doctors? He said, "Of course, I feel just as you do about it, that it is perfectly ridiculous to think that the Government can take care of these men better than they can be taken care of by you doctors in civil practice." This legislation will lead to the building of numerous hospitals, and they will have to do something later with the hospitals when the need for them has passed. Even if there are no veterans they can put someone else in them.

We suggested a committee to work with the Legal Defense Committee to try to coöperate and get their support in Washington by contact with local Congressmen and Senators. It is a well known fact that the local Congressmen will listen more to the local group if they are well organized than they will to any other group.

Of course, the outstanding thing that was done was the election of Dr. E. Starr Judd. He is a Minnesota man and was elected by his friends. A number of surgeons from all over the country came and used all kinds of pressure for Dr. Judd, and I think it was a very wonderful thing. I hoped Dr. Judd would be here this afternoon so that we might see him and have him presented to this body.

The meeting, of course, will be in Philadelphia next year. I think that is one of the things that is difficult for the men in the House of Delegates to determine. The different places go in and ask for meetings and we don't know just what the facilities are, because the men who know are not permitted to come in and state frankly just which place is the best. It would be a fine thing for Mr. Braun if someone could come in and say we know just which town is best equipped to take care of us in the best way. But of course we are not permitted to do that.

I think we would all welcome any questions about the meeting. I would like to second Dr. Braasch's advice that everyone read carefully the published transactions, and I think we ought to hear from Dr. Herman Johnson inasmuch as he has some subterranean method of acquiring information which the others of us do not possess, and I think he could probably give us some additional information. (Applause.)

PRESIDENT BOYER: I don't suppose anyone here ever heard of Dr. H. M. Johnson, commonly called Herman, but Herman, will you come here and give us a few words?

DR. JOHNSON (Dawson): I was one of the delegates to the American Medical Association at Detroit this year. It is a wonderful organization and is becoming more of a real organization all the time. You would hardly recognize the American Medical Association House of Delegates of 1930 as the same organization which met in Dallas when I first was a delegate. They worked hard then, but they work harder now. They do their best for the rank and file of the medical profession. And I want to tell you that some of the members of the House of Delegates are not afraid either. If they think they are right, they will fight for their beliefs. We have found that we have to do the same thing and we get along all right. The American Medical Association is certainly fortunate to have such men at the head of it as it has. I want to say that I don't believe anyone could fill the position of secretary as Dr. West has. We hope Dr. West will be well and strong and able to continue the work he has done so well in the past. In electing Dr. Judd as president, it was a case of the office seeking the man and not the man seeking the office. That is the only way anyone should be elected president.

One of our main troubles is social and state medicine. It is absolutely necessary that we stand by the American Medical Association in every way, because it is only by united action with them and through them that we can fight off state and social medicine. Delegates from the East said they were fighting with their backs to the wall and that if we didn't take the very best steps and go right after it, we would soon be in the same position as the medical profession is in Europe. We might not be able to stop it, but we can modify and direct it to a great degree. Let us continue our efforts along those lines. (Applause.)

PRESIDENT BOYER: You have heard the report of

the Delegates to the American Medical Association. What will you do with the report?

Dr. Savage (St. Paul): I move it be accepted, with an expression of appreciation for what they have done.

(This motion was carried.)

President Boyer: In the spring the conference on Hospitals, Medical Education and Licensure was held in Chicago. It is an annual affair. Dr. Braasch was present at this conference. We would like to have a report from Dr. Braasch covering this conference.

Dr. Braasch (Rochester): I happened to be at a medical meeting in the East and stopped at this meeting on the way back.

REPORT OF ANNUAL CONGRESS OF MEDICAL EDUCATION, LICENSURE AND HOSPITALS

The annual congress of Medical Education, Licensure and Hospitals held in Chicago this year attracted several hundred men from far and wide who are interested in the problems involved. Many of the subjects discussed have reappeared perennially and their solution seems no nearer. In the course of time, however, and as a result of such discussions, many controversial points are cleared, giving room for progress. It is not alone the stimulation of ideas and the comparison of experiences which are of value in conferences of this kind. Probably of greater value are what may be called the by-products, namely the contact of individuals with common purposes and ideals, permitting discussion of major problems as well as allied subjects, devoid of the formality and embellishments of set papers. The value of these informal conversations is frequently worth expense and effort involved.

Aside from the three divisions stated on the program there were gatherings of representatives of many other interests and there were meetings other than those included in the program. Predominant in the attendance at many of the gatherings was a liberal representation of the nursing organization.

Probably the gathering which attracted the most attention was the Conference on Hospital Service and the Cost of Medical Care, on Tuesday, Dr. Harry E. Mott presiding. There were a number of excellent papers in this symposium, which aroused considerable interest in the subjects involved. Dr. Caldwell's contribution was more or less a defense of the present methods of conducting hospitals and of the expense involved, inferring that everything possible was being done under the circumstances to reduce the minimum. It was also his impression that the peak of hospital cost had been reached and would probably recede from now on. He made one claim which is worthy of consideration, namely that the cost of hospitalization to the indigent should not be borne entirely by the hospital, but should be shared in part by the community through taxation. He also called attention to the great value of the hospital as an educational factor, not alone to the medical profession, but to the public as well, and stated that the expense of this activity should not be borne by the hospitals alone.

This was followed by a paper by Dr. James B. Herrick, who discussed hospitals from the viewpoint of the medical staff and pointed out many ways in which the expense could be materially reduced. He suggested that members of the staff be continually on the lookout for means whereby economy could be practiced and that they consult freely with the hospital management in this regard. He felt that much saving could be brought about in the way of nursing; first in regard to group nursing, which he believed gave much economic promise for the benefit of the average patient. He thought that nursing service by the hour might also be applicable in many cases where it is not necessary to have constant attendance. He also stated that in many cases patients are unnecessarily placed in private rooms and would be just as well off, if not better, in wards. While he did not decry the college degree for a nurse, he did not think this was always necessary, but that this type of nurse should be given special duties and responsibilities.

Dr. Herrick felt that hospitalization was unnecessary for examination of patients in most instances. This practice is followed quite freely, largely because it is a matter of convenience to the physician, and also because the expense of this examination, in the minds of many patients, reflects the excellence and thoroughness of the examination. He thought that a flat laboratory charge was frequently unnecessary, and that the laboratory charge should be graded according to the patient's means. He felt that many mistakes were made in hospital construction, which were anything but economic; that with the proper planning and care the cost of construction could be materially reduced.

It was also felt that there should be various types of hospitals, according to the patient's pocket-book, much the same as our hotels. In other words, the hospital should be constructed for convenience, comfort and luxury to fit the patient's pocket-book. A hospital might well be equipped to take care of the ordinary wants of a patient and yet be constructed much more cheaply than one where every luxury was present, as in some of the modern hospitals. In this way the patient's means could be better accommodated. Dr. Herrick also made the remark that he thought the modern hospital today was too standardized and had too many rules. He feels that they should be more elastic and more human in their attitude toward patients.

Dr. Arthur T. Holbrook continued the discussion in a most excellent paper entitled "From the Point of View of the General Practitioner." Dr. Holbrook stated that he was proud to be known as a general practitioner and believed that the pendulum was rapidly swinging back and that the fundamental value of the general practitioner in society was being recognized. He stated that the position and the value of the specialist was over-emphasized; that in the hands of a progressive, up-to-date general practitioner only 10 per cent of patients needed hospital care and that a diagnosis could be made in at least 80 per cent of his patients without any consultation with a specialist. He stated that the art of medical practice was illogically subordinated to the science of medicine; that many patients were unquestionably being hospitalized unnec-

essarily, largely for the convenience of the examining physician, which means unnecessary expense to the patient. By a general practitioner he meant one who has kept abreast with knowledge, investigation and treatment, who after a careful general examination acts as a medical advisor and not necessarily a vendor of drugs. It was his opinion that the average group clinic did not solve the problem of the cost of medical care, but that there was a tendency to do unnecessary examinations in such a group.

Dr. Reynolds, in a paper entitled "From the Standpoint of the Layman," called attention to the uneven distribution of hospitals, saying that the laity should be educated as to the actual cost of care and that if they were there would be less criticism. He believes that the science of healing is making great strides, but that the business of healing lags behind. He thought that the budgeting of medical costs by the layman and paying for the same on the installment plan, as for furniture, might be of value. He stated that the problem centered itself around the cost of care for the middle class patient and that it is the other expenses and extravagances that are a large factor.

Dr. Billings in discussion suggested that hospitals for convalescents might be constructed at a considerable reduction in cost. Instead of paying $5,000 for a bed, such hospitals might be constructed at a cost of $1,000 for a bed, and the rates might be as low as $2 per day. Such hospitals as that could take care of ten or fifteen per cent of the patients in hospitals today. It is Dr. Billings' opinion that physical examinations forty years ago were more accurate than they are today and he states that too much depends upon fine laboratory methods for diagnosis, ignoring ordinary methods which would be sufficient in the large majority of cases.

Mr. Gregory, Manager of the Palmer House, was called upon to make some practical remarks from the viewpoint of the hotel man. It was his opinion that feeding patients in the hospital was not a medical man's business, but that of a hotel man or administrator. He thought that the mental attitude of the patient would be greatly improved if the rooms had more of the atmosphere of the hotel than the hospital, and that an effort could be made to make the patient more comfortable and in a happier frame of mind without increasing the cost.

On Tuesday afternoon I attended the meeting of the Federation of State Medical Boards and Medical Licensure, together with Dr. Sanderson, Secretary of the Medical Examining Board of our own State, and Mr. Brist. We went there with the expectation of listening to a criticism of the Basic Science law and the Basic Science boards, and came prepared to defend them if necessary. However, in none of the papers were there any direct accusations made against the Basic Science examinations, although in several of the papers there was veiled criticism and insinuation. It was quite evident that the "Ancient Order of State Examiners" were not in sympathy with the new order of things. The most that was said in opposition, however, was that the Basic Science Board and the Medical Examining Board had not reciprocated in the various states as they should. Dr. W. L. Bierring called attention to this fact and I think his point was well taken. However, in the discussion of the various papers, several of the Medical Examiners gave vent to criticism and vituperation of the Basic Science Act and questioned its efficacy. Although Mr. Brist arose to defend the Basic Science Act in Minnesota, his remarks were not taken with particularly good grace, and he was not given much of an opportunity to display his wares. In the executive session which followed the open meeting, however, no resolutions were passed which were inimical to the Basic Science Boards.

One left with the impression that the average medical examiner was not in sympathy with the Basic Science methods of controlling irregular practitioners, apparently feeling that his prerogatives were invaded.

There is no doubt about the efficacy of the Basic Science Board in the minds of medical men in states where it has been tried out, and it would be safe to assume that in the course of time its value will be recognized by all.

I also attended the Symposia on the full time system of teaching and on the importance of pathology in medicine. Excerpts of the proceedings of these sections have been published in the Journal of the American Medical Association, and I will refer anyone who may be interested to these.

Suffice it to say that a congress of this kind, embracing the various topics involving the progress of modern medicine, is most interesting and stimulating, and if anyone can spare the time to attend these mid-winter conferences, he will be well repaid for his effort.

WILLIAM F. BRAASCH, M.D.

A motion was made, seconded and carried that the report of Dr. Braasch be accepted.

PRESIDENT BOYER: We are now ready for the report of the Reference Committee. Allow me to state that a different procedure has been adopted than has obtained heretofore. The Reference Committee has been requested to submit a summary of each report with recommendations. Following the report and recommendations by the Reference Committee upon each one of the committees whose work it surveys the discussion will be opened by the chairman of the committee whose work is reported upon. The purpose of this is to facilitate the work of the House of Delegates. Everybody has had a copy of all these committee reports. It is requested that the discussions be to the point and be brief. Dr. Manley, of the Reference Committee, will now be heard from.

DR. MANLEY (Duluth): You have all had a chance to read the Secretary's report. The Reference Committee recommends the careful reading of every word of the report of the Secretary. It gives a comprehensive, bird's-eye view of the activities of the Society during the past year. We also recommend the careful perusal of the addenda to the Secretary's report in the form of a letter from Councilor Savage.

REPORT OF THE SECRETARY

The activities of the secretary's office are widely varied and are increasing as our organization develops. At the present time eight committees not listed in the Constitution are operating. These special committees demand information, notices of meetings, and reports for compilation, all supplied by this office.

An increasing number of requests for information and service in the field of economics and private practice are constantly received.

The secretary's office has assisted several component medical societies, both individual members and committees, in constructing surveys relative to the programs and medical economic conditions in other state societies. This has entailed considerable correspondence and compilation of returns.

The weekly newspaper service to Minnesota newspapers has been continued and a plan developed for it whereby the stories are written in our own office. Thus we are eliminating the purchasing of this service from the State Medical Society of Wisconsin.

Letters to the Consultation Bureau now average five or six a week. These letters are acknowledged in this office and referred to Dr. O'Brien for reply.

Almost daily we receive letters from the medical profession informing us of violations of the Basic Science and Medical Practice Acts. These communications usually require a reply or further investigation. Then they are sent to the State Board of Medical Examiners and frequently to the American Medical Association. This service has become an important part of the routine work of the secretary.

Bookings for Mr. F. Manley Brist, Investigating Attorney for the Minnesota State Board of Medical Examiners, are made through the secretary's office. Since the last Annual Meeting, Mr. Brist has talked to the following groups:

May 2, 1929—Wright County Medical Society, Maple Lake.

May 6, 1929—Hennepin County Medical Society, Minneapolis.

May 14, 1929—Women's Auxiliary, Annual Meeting, Minneapolis.

May 21, 1929—Steele County Medical Society, Owatonna.

May 21, 1929—Lions Club, Owatonna.

May 22, 1929—Redwood-Brown County Medical Society, New Ulm.

Sept. 10, 1929—Washington County Medical Society, Stillwater.

Sept. 19, 1929—Kiwanis Club, Tracy.

Sept. 19, 1929—Lyon-Lincoln County Medical Society, Tracy.

Oct. 14, 1929—Camp Release District Medical Society and Ladies Auxiliary, Montevideo.

Nov. 5, 1929—Southwestern Minnesota Medical Society, Slayton.

Nov. 25, 1929—Blue Earth County Medical Society, Mankato.

Nov. 26, 1929—Stearns-Benton County Medical Society, St. Cloud.

Jan. 11, 1930—Secretaries' Conference, St. Paul.

Jan. 23, 1930—Joint meeting of the Lions and Kiwanis Clubs, Mankato.

March 25, 1930—Lions Club, Stillwater.

March 26, 1930—Women's Auxiliary, Hennepin County Medical Society, Minneapolis.

April 22, 1930—Colloquium lecture, Winona.

May 1, 1930—Semi-annual meeting of Blue Earth Valley Medical Society, Fairmont.

May 13, 1930—Mower County Medical Society, Austin.

May 14, 1930—Iowa State Medical Society, Marshalltown, Iowa.

May 15, 1930—Freeborn County Medical Society, Albert Lea.

May 23, 1930—Colloquium meeting, Wadena.

June 24, 1930—Kiwanis Club, Willmar.

June 24, 1930—Kandiyohi-Swift County Medical Society, Willmar.

July 10, 1930—Wabasha County Medical Society, Wabasha.

The contact with the Minnesota Public Health Association has continued in the same manner as it has in the past years, the relation being a close and valuable one for the purpose of reaching the laity especially in the organization of groups and schools. We regret to say that there are still three counties who have independent seals and who are not coöperating with us in our program. They are McLeod, Blue Earth, and Martin counties.

The following is from a clipping in the Minneapolis Journal of about June 23, 1930:

> Papers for incorporation of the Citizens State Health Association have been filed with Secretary of State Mike Holm by a number of lay and professional citizens as a group to promote "the health of people by natural or drugless means, to cooperate with similar organizations for investigation or promoting of health projects submitted by health agencies in the interest of public health, and to distribute health information by way of literature, publications, health lectures and clinics." Officers are Gustav H. Nybeck, president; Mrs. A. C. McBeath, first vice president; Winifred M. Brachlow, second vice president; Mildred M. Skiff, secretary and treasurer, and C. W. Whittenberg, Fred J. Grande and W. J. Hyman, board of directors.

It is evident that cultists are preparing for the next session of the Legislature and expect to use this agency as a "camouflage" to put across propaganda, hoping to influence legislation.

"Everybody's Health," the popular monthly magazine published by the Minnesota Public Health Association, is a valuable medium with which to disseminate the truth about health. There is so much health misinformation put out by faddists, quacks, and commercial groups that "Everybody's Health" makes a convenient medium to promulgate the truth. This magazine goes into every school in the State of Minnesota and most of the hospitals and to many thousands of lay subscribers. It should be in the reception room of every physician's office and merits the endorsement of all who are interested in the practice of medicine and the health of our people.

The secretary's office has conducted a large part of

the program of the Committee on Public Health Education, especially correspondence and booking of speakers, as well as the newspaper service.

Dr. George Earl, Chairman of the Public Health Education Committee, agreed to give two weeks of his vacation again this year to assist in a state-wide tour for the purpose of fostering good will and better organization among members of the medical profession and also a better attitude on the part of the general public. In every community visited, a meeting of the medical profession was held, including members from the surrounding country, frequently from several counties. This health tour was conducted with the cooperation of the Minnesota Public Health Associations, school superintendents, and various local Parents-Teachers Associations, in the towns of Alexandria, Bemidji, Crookston, Fergus Falls, Marshall, Montevideo, Moorhead, Wadena, and Worthington.

Wednesday, October 30, represented a typical day's program of the tour. It consisted of the following: tuberculosis short course at the tuberculosis sanatorium; health talks at the two teachers' colleges and the high school; a medical economics meeting; a public meeting; a meeting for social workers; and a big health "jamboree" in the evening. There was a large and enthusiastic attendance at all of these meetings.

The secretary attended two programs in each city, except Brainerd, of the series of Colloquium lectures this spring. These were the programs devoted to the Minnesota State Medical Association and the Minnesota Public Health Association.

The Colloquium short courses were sponsored by the Committee on Hospitals and Medical Education of the state association coöperating with the Extension Division of the University of Minnesota. They provided one program each week for eight weeks, covering tuberculosis, heart, obstetrics, hospital management, immunology, cancer, and cultural subjects at an expense of only $50 to the local society. Five cities, Wadena, Faribault, Willmar, Winona, and Brainerd, booked them. A large attendance and much enthusiasm marked the series in each city. The secretary believes that better feeling and better organization among the medical profession are among the outstanding by-products of these courses. It is hoped that something along the same lines can be given again this fall.

The secretary made several long tours of the state, including the towns of Albert Lea, Austin, Bagley, Brainerd, Caledonia, Crookston, Faribault, Hawley, Jackson, Lake City, Lake Park, Litchfield, Mankato, Moorhead, New Ulm, Owatonna, Red Wing, Rochester, Saint Cloud, Saint Peter, Sleepy Eye, Spring Grove, Tracy, Wabasha, Wadena, Walnut Grove, Waseca, Willmar, Windom and Winona, to stimulate interest in the Health Tour and the Colloquium lectures as well as participating in the tours and lectures themselves. He attended meetings of Stearns-Benton County, Camp Release District, Rice County, Freeborn County, and Mower County Medical Societies, and of the Northern Minnesota Medical Association; addressed a large number of medical and health groups throughout the state, such as the Lions Club of Stillwater, the Federated Clubs of Jackson, the graduation class of Naeve Hospital, Albert Lea, the Regional Nurses Conference at Austin; attended meetings of the American Medical Association, the State Secretaries' Conference of the A. M. A., the American Public Health Association, the State Board of Control Social Conference, committees arranging the Interstate Post Graduate Assembly, and the Iowa State Medical Association; made several trips to Duluth to confer with the President and the local committees in arranging the Annual Meeting; and held innumerable smaller conferences in Saint Paul and Minneapolis on matters that relate to the business of the Minnesota State Medical Association, namely, meeting of the Executive Committee of the Hennepin County Medical Society, meetings of the Committee on Scientific Assembly, regular meetings of the Council.

The secretary wishes to extend his personal appreciation for the splendid coöperation received from those who accompanied him to the various gatherings of the medical profession throughout the state. In particular he wishes to thank Dr. S. H. Boyer, Dr. R. M. Burns, Dr. George Earl, Dr. E. J. Engberg, Dr. J. M. Hayes, Dr. M. S. Henderson, Dr. N. O. Pearce, Dr. F. J. Savage, Dr. Theodore Sweetser, Dr. W. W. Will, Dr. C. B. Wright, Dr. J. A. Myers, Dr. Leo G. Rigler, Dr. Walter H. Ude, Dr. F. F. Callahan.

Dr. F. J. Savage and the secretary attended the medical meeting at Hastings at which a resolution petitioning the House of Delegates for organization of a Dakota County Medical Society was drawn up. With the organization of this society, only one county, Lake of the Woods, in the entire state of Minnesota will remain unorganized or unaffiliated with some county organization.

The ever enlarging attendance at county meetings of the medical profession is doing much toward making a stronger organization for our state, we believe. We are willing to arrange programs and aid in securing speakers for any county medical society. News items and notes of meetings from county societies are welcome. They cement our organization. We want to feel that the county societies are part of us and that this is their office. We hope they will call on us.

Two fruitful state meetings were held in the Twin Cities during the year. One was Dr. Boyer's meeting of committee chairmen, held in Minneapolis in connection with the meeting of the American College of Physicians in that city, an unusual and effective gesture toward coöperation and centralization.

The other was the annual secretaries' conference held in Saint Paul, January 11. Thirty societies throughout the state were represented at this conference. Officers of the state association and many other members were present. The important problem of what to do about inflammable *x*-ray films was discussed by experts from the Eastman Kodak Company, from the fire department, and from the medical profession, and discovered to be no problem. It was clearly indicated that the acetate film, which is no more dangerous to have around than so much paper, can be used just as effectively as the dangerous nitro-cellulose variety now,

and no more expensively either, if you consider the expensive and elaborate filing systems with their fresh air vents and sprinklers that are necessary to proper protection of the nitro-cellulose film.

Outdoor storage vaults were recommended for such of the old inflammable films as it is necessary to keep for teaching, clinical, or legal purposes.

The fundamental and practical character of the American Heart Association's program as indicated by Dr. I. C. Riggin, executive secretary, New York, recommended itself to the conference. Scientific research, evolution of a standard nomenclature to aid in diagnosis, and sundry suggestions as to care and rehabilitation of convalescent cardiacs were embodied in it.

These were two important and interesting items on this program which proved to be one of the most valuable ever held by the association. Reports from local societies and meetings of important committees occupied more than the day allotted to the conference and demonstrated again the value of these secretaries' meetings to the closer organization and more efficient cooperation among the medical profession in this state.

Your secretary was impressed on his attending the American Medical Association meeting at the amount of organization that has taken place in the medical profession in the past few years throughout this country. I had the privilege of being the only state secretary who was invited to attend a meeting, which began at 12 o'clock noon and lasted until midnight, of local full-time secretaries. All these were laymen with the exception of one from Brooklyn. Such cities as Detroit, Brooklyn, Milwaukee, Saint Louis, Cincinnati, Toledo, Chicago, Des Moines, and others were represented. It is gratifying to know that so many large centers have made definite progress in organizing the profession into strong units.

The problems that have confronted these locals in recent years have been met by them in very much the same manner as they have been met here. Strong committes are working in these organizations. Mr. Burns, who will speak at the medical economics meeting, will give an outline of what these locals are doing and what the functions of the lay secretary are.

We are interested to note that the House of Delegates of the American Medical Association passed a resolution introduced by the Minnesota delegation which provided for a committee of five to investigate national legislation and make a report to the House of Delegates and the Board of Trustees.

Another resolution was passed creating a Board of Medical Economics in the American Medical Association. This resolution came from California.

The universal acclamation with which these two resolutions were received indicates that the profession throughout the United States realizes the problems that are before them.

Report from attorneys, Oppenheimer, Dickson, Hodgson, Brown, and Donnelly:

"Anna Anderson vs. Dr. Henry L. Ulrich of Minneapolis. Case pending. Not on the calendar of Hennepin County for trial. Undoubtedly will never be brought to life.

"Dr. F. D. Gray, of Granite Falls, Minnesota, vs. George Griger. No developments.

"Dora Halter vs. Dr. William E. Browning of Caledonia, Minnesota. Case disposed of by the death of Dr. Browning. A dismissal was subsequently filed in Court."

At present, membership by societies of the state association, as compared with December 31, 1929, is as follows:

	Dec. 31, 1929	July 2, 1930	Affiliate	Association	Total
Blue Earth County	31	30	1		31
Blue Earth Valley	22	23	5		28

TOTALS	2,053	2,027	65	8	2,100

The growth of your program has been rather rapid and expansive. There is enough experience at hand now to consider the advisability of curtailing the factors of least importance. The administrative expense has been unusually low due to the interest of those participating in the program and increased administrative expenditures will be necessary immediately.

The success of a central office in rendering real and lasting service to the society must depend upon proper guidance from state officers and committees and the

loyal efficient coöperation of the component units with the state organization.

E. A. MEYERDING.

ADDENDA TO THE SECRETARY'S REPORT

The following letter written by Councilor F. J. Savage to the members of the Ramsey County Medical Society contains so much of value that it was thought advisable to include it in the Secretary's Report so that all the members of the Minnesota State Medical Association would be familiar with its contents.

To the Members of the Ramsey County Medical Society:
Dear Doctor:

At the April meeting—the 28th—the question of the dues of the State Medical Association will come up for discussion.

The fundamental question is not so much that we are spending $15.00 per year for support of the State Association but are we getting results from this expenditure sufficient to justify this amount? So many statements are made without foundation that a consideration of the various phases of State Association activities is desirable.

Since the statement has been made that membership in the state and county societies has fallen off since our dues advanced in 1927 to $15.00, let us review the membership from 1926 to date of both the State Association and the County Society:

Year	Total No. of M.D.'s registered in State	State Society including Affiliate members	Ramsey County including Affiliate
1926		2,134	327
1927		2,065	326
1928	3,341	2,126	332
1929	3,347	2,189	325

These figures speak for themselves.

The effect of the Basic Science Law on admission of chiropractors to practice in the State has been that from 1922 through 1927 there was an average of 38 per year. Since the passage of the Basic Science Law they have averaged one per year.

Since the passage of the revised Medical Practice Act, the attorney for the Board of Medical Examiners reports on two years' work as follows:

98 cases investigated
27 cases in court
23 convictions
2 dismissals
2 not guilty

and in addition 16 have left the state and one has quit entirely.

This work has been possible because of the revision of our Medical Practice Act due to the work of the Committee on Legislation of the State Association.

Without our Legislative Committee the chiropractors would have reduced their study from 24 to 18 months. Osteopaths and chiropractors would be practicing in our tax supported hospitals. An anti-vaccination bill would be in force. An anti-vivisection law would be in force. Naturopaths would be legally licensed to treat the sick in Minnesota. Full time University and state asylum physicians would be prohibited from accepting fees for any private work. Malpractice suits could be started within a six year period from the time the alleged malpractice occurred. It is a well known fact that in the time when the period was six years, instead of two years, that the majority of suits were started after the two year period. If the law had not been changed it is probable that our malpractice insurance would now be costing double what it does. The difference would be a greater sum than our annual dues of $15.00 to the State Association. In addition note the Ramsey County report for 1929. Not one malpractice suit filed against a member during the past year. An attempt was made at the 1929 session of the Legislature to go back to the six year period but this was defeated.

Before your Legislative Committee had money with which to work (in 1923), the osteopath was granted the right to practice minor surgary, administer anesthetics, narcotics and antidotes. In 1929 a bill granting still more legal rights was defeated.

In 1929 the venereal disease laboratory of the State Board of Health at the University was continued in operation largely through the efforts of the Legislative Committee.

In 1927 the Committee aided in securing an appropriation of $25,000 for research work at the University.

If it were not for your Legislative Committee, your fees for work done under the Workman's Compensation Law would now be dictated to you by the State Industrial Commission.

The atmosphere created by the Legislative Committee made easy the passage of the bill giving legal status to the staff of the Ancker Hospital and accounts for its present organization.

The passage of the Massage Bill at the 1929 session was done in the face of almost insuperable obstacles. This has far greater significance than the majority of medical men in Minnesota realize. Under the old Massage Law nearly every irregular who wanted to treat the sick could get a massage license and then assumed the title of Doctor. The result of two years of the operation of the law was deplorable. During the first eighteen months the old Massage Board licensed 269 to practice. Today there are 209 licensed masseurs in Minnesota. The new law places the licensure in the hands of the State Board of Medical Examiners and prohibits their use of the title of Doctor. We never had any quarrel with legitimate masseurs.

The Legislative Committee of the State Association has done this work for the people of the State of Minnesota and the members of the profession. The Council of the State Association has the utmost confidence in the expending of this fund by the Legislative Committee—however, the Chairman of the Legislative Committee has always insisted that members of the Council audit and inspect the accounts and such an audit and inspection has always been so conducted.

The activities of the Committee on Public Health Education are so many and varied that a brief description is impossible. Within the past ten years medical men throughout this country have awakened to the

necessity of maintaining contact with the public and we believe that the work of this Committee through the channels of the press, the radio, the distribution of literature and the lecture platform ranks well to the front among the states of the Union.

Your State Association has, as a Reserve Fund in securities, handled by the First Minneapolis Trust Company a total amount of $22,500.00. This money cannot be expended except for investment and re-investment without a vote of the Council. The beginnings of this sum go back to the time that Dr. Hill of Minneapolis was treasurer and represent careful savings over a long period of years. We don't know what this will ultimately be used for. When it increases to a sufficient sum the House of Delegates may instruct the Council to use the interest for the support of some physicians who have reached a helpless old age and have nothing of their own. The existence of this fund needs no defense. Criticism of the existence of this fund is almost beyond comprehension.

The Medical Society of the State of New York has annual dues of $10.00 per member but with 11,960 members this amounts to $119,600 annually. The osteopaths of Minnesota assess their members $20.00 per year, the chiropractors $15.00 per year, and the naturopaths, who have struggled for the past three legislative sessions for legal recognition, have dues of $200.00 per year. In Toledo the physicians pay $35.00 per year, in San Francisco $50.00, Brooklyn $35.00, Atlanta $25.00, Detroit $30.00, Fort Worth $25.00, Kansas City, $25.00, Portland $25.00, Richmond, Va., $25,00, and St. Louis $30.00.

We are faced with the question of whether or not we shall maintain an aggressive front in guiding legislation vital to the public and our interests and in the matter of public health education and in other fields of activity by maintaining our dues as they are; or shall we retrogress, stop our contact with the public, let every quack flood the Legislature with cult legislation, and try to forget that by virtue of our training in a special field we have a duty to the public in matters of public health.

Sincerely yours,
F. J. Savage, M.D.,
Councilor, Fifth District.

A motion was made and carried that the report be adopted as read.

President Boyer: The report is adopted, and is now open for discussion.

In connection with the relief for veterans of the World War, I don't think the American Medical Association House of Delegates took any action on this. Some man got up and offered this solution to the problem: He said, "Issue to these veterans a policy similar to a sick and accident policy and let them do what they do when they have an accident in civil life. Have a regular family physician and a regular hospital and make a claim to the Government." That seemed to me to be very feasible. I don't remember any action being taken on it.

Dr. Manley: The next is the report of the Treasurer. Without going into details, the receipts as given are $39,527.66; expenditures in 1929, $38,234.19; balance December 31, 1929, $1,293.47.

President Boyer: Dr. Schulze, will you please read your report.

A. G. Schulze, M.D., *Treasurer.*

Dr. Manley: We recommend the adoption of the report.

President Boyer: I wish to state that the report has been studied in detail by the Council. Is there any discussion of the report? If not those in favor of the motion will so signify.

Motion to accept the report was carried.

Dr. Manley: Next is the report of the Committee on Public Health Education.

REPORT OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION

To Members of the House of Delegates:

The Medical Profession should have a definite policy in regard to its relation to the public. No one is better qualified than the graduate licensed medical man to direct the public in health matters. Any progress in the end will be largely dependent on the attitude, scientific ability and coöperation of the two thousand individual members of the State Association in solving the public health and economic problems. The public is interested in the care and cost of being sick. The medical man is facing a rapidly changing set of circumstances as regard his practice.

This committee was primarily organized to assist in creating public opinion favorable to scientific health legislation. While medicine has a scientific side it also has economic problems and the two never have been and cannot now be separated. Many organizations except that of the medical men themselves have been busy for years in directing medical practice, as evidenced by lay public health associations such as tuberculosis associations, the cancer group, child welfare, the endowed foundations such as the Milbank Memorial Fund with its millions and the Chicago Institute that was so much in the public eye a year ago. Tax supported agencies, federal, state, county, and city, are taking increasingly active interest in public health. The above agencies and organizations are no doubt sincere in their purposes even though medical men have not always been in accord with their policies. Then we come to those organizations that are distinctly questionable as represented by the cultists, fake health magazines, anti-vaccinationists, and what not.

The committee, having limited funds and no experience, spent its first year largely in an analysis of the situation, conferring with lay experts and securing criticisms and cross sections of opinion from members of the State Association as to policies and methods to be pursued. It was not until after having interviewed in small group meetings a considerable cross section through the state that definite plans were set in action.

By 1930 the following activities were taking place:

Hygeia and *Everybody's Health* sent to members of the Legislature so that they may be properly informed on matters of health.

Radio talks have been given weekly over WCCO. These are financed by the Committee.

Speakers Library.—Folders on 263 subjects are on file and upon request material is sent to members of the Association.

Speakers Bureau has not been extensively developed because of the expense involved in sending out speakers.

Meetings.—During the year a two weeks Health Tour was put on with the coöperation of the Minnesota Public Health Association, various local Parents-Teachers Associations, and school superintendents. Public Health and Medical Economics meetings were held at

Wadena, Moorhead, Crookston, Bemidji, Worthington, Alexandria, Marshall, Montevideo, and Fergus Falls.

Minnesota Public Health Association and its eighty-seven county public health associations, through them the tuberculosis sanatoria and with them contact with the Parents-Teachers Associations, and the Women's Federated Clubs, and numerous school systems, have been advantageous to use in putting across our part of the Public Health Education Program. The joint secretaryship of Dr. Meyerding makes it possible for the Minnesota State Medical Association to put on programs that are comparable to those put on by other medical associations and obtain results that would otherwise be impossible.

Stenographic Help.—This committee is charged with the services of a full time stenographer, a part of whose time has been given to the work of other committees having no budget, thereby correlating the work of some of these committees whose interests touch on the matters of our relations with the public.

Minnesota Medicine.—A page each month in this journal is devoted to the activities of the Committee; it is an open forum and acts as a clearing house for many of the problems studied by the committee.

Diphtheria Prevention Campaign.—The attention of the profession has been repeatedly called to this campaign with the suggestion that they prepare themselves to follow out the plan of immunizing every child between the ages of six months and eighteen months. The Minnesota Department of Health has sent to all the physicians of the state literature and posters. This fall the Committee in conjunction with the Minnesota Public Health Association will send out a poster.

Newspaper Service.—A weekly health story was mailed to 270 newspapers in Minnesota. The stories are now being written in the secretary's office.

Mr. Brist.—One of the most effective educational activities has been the sending of Mr. F. Manley Brist, Investigating Attorney for the Minnesota State Board of Medical Examiners, before medical and lay groups. During the year he has appeared before 16 county societies, before various luncheon clubs, the Women's Auxiliary. In Mr. Brist and his talks we have a striking example of the results accomplished by the program of the Minnesota State Medical Association during the past years. Mr. Brist brings before these groups the direct accomplishments of the new Medical Practice Act and the Basic Science Law. The Committee on Public Health Education finances this part of the program.

Central Health Council.—This is an important but difficult liaison that should function to secure more intelligent public health activities, but has not yet been well organized in Minnesota.

Public Health Nurses.—The committee has coöperated with the Committee to Study Public Health Nursing Problems. Conferences were held to bring about closer coöperation between the Public Health Nurses and the medical profession and to make it possible for the Public Health Nurses to accept the viewpoints of the medical profession in regard to Public Health.

Coöperation with the Committee on the Cost of Medical Care.

Coöperation with the Women's Auxiliary and participation in its program.

Minnesota State Fair.—About three years ago the Minnesota State Fair Board abolished health meetings and health exhibits at the Minnesota State Fair. These exhibits were placed without expense to the Fair Board by various organizations interested in Public Health. The Board, however, did furnish exhibiting space. Some of the organizations participating in this exhibit were: Medical School, University of Minnesota, Minnesota State Medical Association, Minnesota Dental Association, Hennepin County Tuberculosis Association, Minnesota Nurses Association, Minnesota Public Health Association, Ramsey County Public Health Association, and Minnesota Department of Health. The Committee recommends that a resolution be sent to the State Fair Board asking it to consider the possibility of re-establishing the Public Health Building. Health Education is essential to the welfare of the people in Minnesota and we feel that we should make an effort to bring about again this plan that proved successful several years ago.

The committee has advocated the adoption of the Hennepin County Medical Society's plan of coöperation with lay health organizations and has urged every county society to adopt this plan of having medical men on the Boards of Directors of all lay health organizations in their county.

Throughout the three years of activities there has been an effort made by the committee to enlist the criticism and support of every member of the State Association as we realize that results will be accomplished on the question of our relations with the public and the practice of medicine only in proportion to the interest the individual practitioner takes in his contacts with the patient and the public; in other words, the contribution each one of the two thousand men of the State Association makes toward solving economic and public health problems that affect both the medical practitioner and the patient. The small group meeting has done more to eliminate petty local disagreements among medical men and to clarify their thinking on public health and medical economics than any other activity of the Committee.

The forces of state, industrial, and insurance medicine, the large endowed philanthropies, free clinics and complicated equipment used in modern practice are vitally influencing scientific medicine, economics and public health. The Medical Profession must be organized and have definite policies if it is to have any share in determining:

1. Who Shall Control the Health Policies?
   a. The Laity?
   b. Charlatans?
   c. The Medical Profession?
2. What Shall These Health Policies Be?

Respectfully Submitted,

H. B. Bailey, J. S. Holbrook,
R. O. Beard, John A. McIntyre,
B. J. Branton, F. H. Magney,
Henry W. Cook, F. H. Neher,
C. O. Estrem, Theodore Sweetser,
H. F. Helmholz, George Earl, *Chairman.*

Dr. Manley: This is a particularly full and complete report and the Reference Committee wishes to commend the Public Health Committee on the excellent work done. We approve a recommendation of the committee that a resolution be sent to the State Fair Board asking them to consider the possibility of re-establishing a Public Health Building which was abolished three years ago.

President Boyer: You have heard the report. What shall we do with it?

A motion was made and carried that the report be accepted.

Dr. Earl (St. Paul): I have a copy of the Minneapolis Tribune which carries an advertisement of "Theronoid" which bears the endorsement of the Women's Federation of Clubs. If you men don't know what Theronoid is, it is supposed to relieve catarrh, rheumatism, high blood pressure and many other ills. That problem we have to return for some consideration by Hennepin County itself and also take it up with the Women's Auxiliary.

The studies now being made by the Committee on the Cost of Medical Care are placed in three groups:

1. Survey of data showing the incidence of disease and disability requiring medical service and of extending facilities.
2. Studies of the cost of medical service and returns to the agents furnishing such service.
3. Analysis of significant special experiments in provision of medical care.

While no definite report has been completed to date solving the problem of cost of medical care, all who are interested in the cost of medical care have an opportunity to express opinions as to the improvements that can be made and disadvantages of already selected courses of procedure prescribed by others.

In this state we have this unique relationship with the public health agency, and we believe that by working the two together we are able to receive the most efficient results.

I know everybody in this room received a copy of the Graphic, and you can't pick up the Kiwanis Magazine or any other magazine nowadays that there isn't an article in it by somebody on the cost of health.

While it is true that economics is the basis of all progress, the factors underlying the problem of health and sickness are, first, finding human happiness through efficient medical services, and, second, an economic factor. Now, scientific knowledge, ability, simplicity of diagnosis and more efficient care and treatment have progressed to a place where only the economic factor blockades the pursuit of the patient of moderate means in finding human happiness. You might be interested to know that in this analysis it is stated that the doctor's share of the cost is 17.6 per cent, or between one-sixth and one-fifth of the total cost goes to the doctor. Private duty nurses get 8.2 per cent; practical duty nurses, 5.8 per cent; attendants, 4 per cent; dentists, 5.8 per cent; hospitals 29.3 per cent; druggists and medicines, 27.3 per cent. You see, the cost for drugs and medicines is 27 per cent as compared with 17 per cent that goes to the doctors. Of course, that is the great quack medicine graft. Chiropractors and osteopaths, 2 per cent. The total approximated cost of medical care secured from Dr. W. S. Rankin's report in the American Journal of Public Health, April, 1929, totals $2,500,000.00. In addition to the expense of medical care there is a great loss to the people of the United States from decreased earning capacity, and this is estimated at $2,000,000.00, which is estimated at 44.4 per cent of the total cost of illness. The average wage earner, according to the United States Bureau of Labor statistics, pays $60.39 a year for medical service, which is 55.6 per cent of the total cost of illness to the average individual.

How is this going to be met? None of us feel that the hospitals are trying to profiteer, but there may be some leaks. Is it reasonable to suppose that is the only solution? And we have industries and department stores that are providing health service. Probably some type of insurance as Dr. Meyerding mentioned for the veterans is the best. Increasingly the hospitals are hiring full time salaried doctors with offices in the hospital, operated for non-profit, or rent offices to doctors practicing for fees.

Many anticipated solutions to find ways and means to reduce the burden of cost to the patient of moderate means are being tried out. Hospitals are providing greater spread of rates, eliminating or combining special charges. Flat rates and sliding scale of charges are provided for individuals according to their means or ability to pay. Long time payments or the installment system is being tried with hospital charges.

The question has been asked by some of our leading authorities regarding hospital and medical costs, whether the patient of moderate means could pay for his medical care even if the entire hospital and medical world would adopt every one of the new policies outlined in this study? No one is able to answer this question for the present. No one knows what the individual can afford to pay. While the income of the general middle class is approximated from less than $1,000 to $3,000 per annum, the economic ability of the individual must be considered when individuals have different tastes and modes of living, and depends greatly on his ability to pay for medical care. If the individual is an appreciative type for the service rendered to him and has a knowledge that the cost is not exorbitant, he is most willing that the accounts for medical attention be given his immediate consideration. The individual who is willing to forego minor comforts and luxuries will meet the cost of medical care with little difficulty.

The attention of an individual, recently, has brought this matter to a degree of enlightenment. This individual had a compound spiral fracture of the leg. His hospital bill amounted to approximately $250.00 and the doctor, at that time, had not sent him a statement. He borrowed funds and together with the small amount of his savings, paid the hospital bill promptly. Thereupon, he borrowed $100.00 from a loaning agency and paid the bone specialist. After paying this amount

back on payments of $5.00 a week, he again borrowed $100.00 and paid his family physician.

Relative costs are not high when one compares our modern standard of living today with that of twenty-five years ago. While there has been increased cost in living expense since the war, as well as increased cost in supplies and equipment to the hospital and doctor, there has been little increase in the cost of hospital care to the patient in a percentage of comparison to the increased costs of hospital operation, keeping in mind the cost of medical care of fifteen to twenty-five years ago with the average income of that time in comparison with today.

Perhaps state medicine, free or part free clinics, and hospitals would solve the problem of the high cost of medical care to the individual, but who is going to pay the actual cost of this service. It is unnecessary to state that there are tangible ways of reducing the cost of medical care through securing better management and control of hospital economies in refusing the patient unnecessary comforts, special nurses when not necessary and refusing private and semi-private rooms to individuals who cannot afford the more expensive rooms, and installing a system of group nursing. Hospitals are not profiteering although 29.3% of the medical costs are charged to hospital care.

Equal Distribution of Costs.—The unequal distribution of the cost of illness is perhaps more or less the source of our trouble. Canada has attacked this problem by taxing all citizens and sharing a portion of the medical costs. Public health and prevention of disease is now one of our tax supported movements. Is it reasonable to believe that we should come to an equal distribution in taxing all individuals to bear a portion of the burden of the cost of illness? In many industries and department stores group health and accident insurance are being purchased at an average cost of seventy-five cents per month to individuals. Some urge if such a plan were made effective to all individuals of the United States, hospitals, doctors and medical attendants would be assured of payment of their charges; free work to a large extent would be discontinued and patients would have the free choice of the doctor and hospital, if needed, and compensation insurance would be discontinued, which would provide increased wages to the employees and all members of the individual's family would be entitled to insurance on this proposed agreement.

This form of distribution of costs appears to be the most favorable that would aim to work out with little difficulty and would provide a greater degree of economic happiness to all.

Future of Medical Care.—According to the last report of the American Medical Association several of the small hospitals have been consolidated to provide less overhead and duplication of equipment. While mergers have their faults and failings, to a certain degree mergering does promote efficiency and reduces overhead costs. Probably the hospitals of tomorrow will include full time salaried doctors with offices in the hospital, operated for non-profit, or rent offices to doctors practicing for fees. As we take cognizance of the progress being made in the realm of medicine, we should be concerned with the trend of economic advances also. The hospital of tomorrow may embrace all of the medical units for complete medical care.

President Boyer: I think Dr. Earl stands prepared to answer any questions that any of you desire to ask. The Chair desires that you do ask questions.

Dr. Wright: If one can first determine the major costs of medical practice something may be accomplished. In the first place there is expense incurred through loss of time by the injured employe. A prolonged stay in the hospital is another expense, and this might be reduced by establishing a type of hospital which is less expensive, similar to the convalescent hospitals in New York. Another problem is use of patent medicines. I think Dr. O'Brien is attacking this in a very intelligent and helpful manner. Dr. Earl and his committee are doing a tremendous work along this particular line in the way of popular education.

President Boyer: Dr. Locken.

Dr. Locken: I might just say one thing that has been my personal experience. I have served as chairman of the Committee on Public Health of the League of Minnesota Municipalities for the past eight years. I have given them a report each of those eight years. We have started this work out from nothing, until the past year they made the public health one of the main considerations of their program for the coming year. I think the important thing of this whole endeavor of the medical profession in getting contact with the public is to come out frankly and present problems of public health to the people in just these ways. I found a very anxious interest to know more about these things on the part of the people. As we do more of that work we will find we will have to spend less money on our actual legislative programs. I think we have had to force it down their necks in the past years because there has been so little preliminary work. But I think in future years we will never have to do this if we first give them some of the information they are entitled to. The fact that we have spent so much money on the Legislative Committee in the past year means that we are just turning over the soil for the first time. I think if we go at this in the right way it will bring increased benefits in the future.

President Boyer: To accept the report of this committee is tantamount to approving the continuation of the committee and the continuation of the expense. We would like to have others ask questions and make remarks before we dispose of this report. We have an exhibit from the American Medical Association in the display here in which Theronoid and Pfunder's pills are touched upon.

Dr. Pearce (Minneapolis): The matter of the Pfunder tablet has been up many times before the Hennepin County Medical Association. In our opinion, at least, we have felt the best thing to do was to do nothing, that any attempt on our part to fight that thing merely serves to advertise it more. The newspapers of Minneapolis have been coöperating with us, and a great many advertisements of that character have been turned down by them. I don't think we appre-

ciate sufficiently the work Dr. O'Brien is doing on the radio. All those who listen to the merits of Sargon as broadcast on KSTP should appreciate the fact that WCCO allows a censorship of these things by Dr. O'Brien, and I think we should go after KSTP and try to get them to permit the same thing, but otherwise I think we should ignore it.

The report was here accepted by a vote.

PRESIDENT BOYER: The Reference Committee.

DR. MANLEY: Next is the report of the Editing and Publishing Committee.

REPORT OF EDITING AND PUBLISHING COMMITTEE

January 1, 1929, to December 31, 1929

In presenting this, the twelfth annual report on the publication of the Association's journal, MINNESOTA MEDICINE, for the calendar year 1929, this Committee is pleased to announce that the journal continues to operate at a profit, the cash receipts for the year being $1,081.52 in excess of expenses. This amount has been remitted to the treasurer of the Association. The net cash receipts for 1929 showed a gain over the preceding year.

The twelve issues of the journal included in Volume XII, 1929, contained a total of 1,244 pages, an average of 103.6 pages for each month. Of this total, 820 pages were devoted to reading matter and 424 pages to advertising, an average for each monthly issue of 68.3 pages of reading matter and 35.3 pages of advertising. Had all the editorial material supplied readers of the journal during the year been published in book form, it would have made a volume of 1,000 pages with nearly 200 illustrations.

The total number of articles published during the year was 129, of which 28 were case reports, and one article by a layman. Other case reports and discussions of interest not listed as individual contributions appeared in the Proceedings of the Minnesota Academy of Medicine and the Transactions of the Minneapolis Surgical Society. The total number of illustrations included in all articles published was 195, an average in excess of 16 for each issue.

In April, 1930, the vacancy in the editorial staff left by Dr. F. W. Schlutz, who is now located in Chicago, was filled through the appointment of Dr. Lewis M. Daniel of Minneapolis as Assistant Editor in charge of the abstract department. Dr. Daniel has already communicated with the supervisors of the various sections in the abstract department and through their cooperation hopes to continue this section as a leading department in the journal.

An effort is being made this year to create more interest through the offices of the Associate Editors in the general news items published. Each Associate Editor has been urgently requested to collect items of interest concerning members in his particular district, sending them in for publication at a stated time each month. While news items have been received intermittently from the Associate Editors in the past, it is felt that a definite time and amount of material required will do much to improve the department of General Interest items during the coming year.

It is gratifying to report that MINNESOTA MEDICINE continues to be regarded as one of the best of the state medical journals. Since the publication was established more than a dozen years ago, earnest efforts have been made to maintain a high editorial standard. Advertising has been carefully censored, and with rare exceptions nothing has appeared in the columns of our state journal not conforming to A. M. A. standards. The American Medical Association tells us that the journal is highly regarded among the better class advertisers. Undoubtedly our advertising volume could be materially increased were we willing to accept border line advertisements.

The circulation of MINNESOTA MEDICINE for the year 1929 is reported as follows:

Members (paid)	2,058
Members (delinquent)	140
Outside subscriptions	118
Miscellaneous copies distributed (exchanges, complimentary copies, advertising copies, etc.)	289
Surplus on file	120
	2,725

The following report of receipts and disbursements was submitted to the secretary of the Association in January, 1930:

Cash Receipts

Subscriptions, Members	$ 4,116.00	
Subscriptions, Non-members	428.20	
Advertising	9,294.79	
Advertising Dividend	377.53	
Illustrations	5.58	
		$14,222.10

Disbursements

Journal expense	$11,953.89	
Discounts allowed:		
Advertising	$1,172.29	
Subscriptions	14.40	
	1,186.69	
		13,140.58
Surplus cash in bank		$ 1,081.52

Respectfully submitted,

EDITING AND PUBLISHING COMMITTEE.

J. T. CHRISTISON, *Chairman.*

DR. MANLEY: The Reference Committee recommends the adoption of this report, with the following recommendation:

In view of the rapidly changing economic conditions affecting the medical profession, and its many great problems constantly presenting themselves for solution, we believe that more attention should be given to the consideration of economic problems in the State Journal and that more space should be devoted to questions aside from the scientific side of medicine. The Committee also recommends that some consideration be given to the question of employing a special editor for this purpose.

A motion was made and carried that the report be accepted.

Dr. Drake (St. Paul): I want to thank the members for their support of the magazine and want to ask their continued support.

Dr. Manley: We now have the Necrologist's report.

NECROLOGIST'S REPORT

June, 1929, to May, 1930

MEMBERS OF MINNESOTA STATE MEDICAL ASSOCIATION

F. A. Allen, Ironton. Born 1876. George Washington University of Medicine, 1905. Died May, 1929. Age 53.

Louis N. Benepe, Saint Paul. Born 1862. Missouri Medical College, St. Louis. Died Feb. 14, 1930. Age 68.

Floyd E. Best, Wells. Born 1887. Northwestern University, 1911. Died Nov. 9, 1929. Age 42.

C. W. Bjorgo, Cannon Falls. Born 1881. Rush Medical, 1918. Died May 7, 1929. Age 48.

William J. Byrnes, Minneapolis. Born 1859. University of Michigan Medical School, 1882. Died Nov. 4, 1929. Age 70. Past President Hennepin County Medical Society.

Charles L. Carman, Saint Paul. Born 1859. University of Minnesota, 1897. Died Dec. 13, 1929. Age 70.

Alva A. Conley, Cannon Falls. Born 1890. University of Minnesota, 1914. Died March 11, 1930. Age 40.

Paul Burns Cook, Saint Paul. Born 1877. University of Minnesota, 1900. Died Feb. 9, 1930. Age 53. Vice President Ramsey County Medical Society.

Horace S. Davis, Duluth. Born 1855. Ann Arbor, Dartmouth, 1884. Died May 4, 1929. Age 74.

W. G. Eisenman, Chisholm. Born 1885. University of Michigan, 1909. Died Dec. 9, 1929. Age 44.

Louis McCargo Fowler, Rochester. Born 1901. University of Pennsylvania, 1924. Died July 1, 1929. Age 28.

Liston Q. Greeley, Duluth. Born 1868. University of Minnesota, 1897. Died Sept. 23, 1929. Age 61.

H. N. Hovde, Duluth. Born 1861. University of Oslo, Norway. Died Dec. 24, 1929. Age 68.

John H. James, Mankato. Born 1846. New York University. Died Sept. 19, 1929. Age 83.

Aloysius Julius Kaufman, Franklin. Born 1875. University of Pennsylvania Medical School, 1899. Died March 23, 1930. Age 55.

A. A. Law, Minneapolis. Born 1872. University of Minnesota 1894. Died July 9, 1930. Age 58. One of the founders of the American College of Surgeons.

Arthur E. Lund, Saint Paul. Born 1890. Rush Medical College, 1925. Died Aug. 10, 1929. Age 39.

Charles Stanley McVicar, Rochester. Born 1880. Western Medical College, London, 1904. Toronto University, 1907. Died June 29, 1929. Age 49.

Marion A. Mead, Minneapolis. Born 1860. Women's Medical College of the N. Y. Infirmary for Women and Children, 1895. Died Sept., 1929. Age 69.

A. G. Moffat, Howard Lake. Born 1865. University of Minnesota, 1895. Died Dec. 18, 1929. Age 64. President Wright County Medical Society.

Louis A. Nippert, Minneapolis. Born 1860. Miami Medical College of Cincinnati University, 1883. Died Nov. 6, 1929. Age 69. President Hennepin County Medical Society. President Minnesota Academy of Medicine.

C. K. Onsgard, Halstad. Born 1863. Eclectic Medical College of Cincinnati, 1887. Died Nov., 1929. Age 66.

C. Eugene Riggs, Saint Paul. Born 1853. College of Physicians and Surgeons, Baltimore, Md., 1880. Died April 3, 1930. Age 77.

Olaf Thorstein Sherping, Fergus Falls. Born 1864. Keokuk Medical College, 1893. Died Dec. 7, 1929. Age 65.

Peter Theodore Torkelson, Lyle. Born 1881. University of Illinois Medical College, 1908. Died Feb. 18, 1930. Age 49.

J. P. Von Berg, Albert Lea. Born 1858. Hahnemann Medical College, Chicago, 1884. Died Dec. 5, 1929. Age 71.

Henry E. Webster, Duluth. Born 1862. University of Toronto, 1884. Died March 7, 1930. Age 68.

Mary J. S. Whetstone, Minneapolis. Born 1849. University of Michigan, 1882. Died Oct. 24, 1929. Age 80. Vice President State Medical Association.

Arthur W. Whitney, Saint Paul. Born 1864. Queens College, Kingston, Ontario, 1888. Died Sept. 14, 1929. Age 65.

L. L. Gibbon, Lowry. Born 1875. University of Minnesota, 1897. Died 1930. Age 55.

PHYSICIANS NOT MEMBERS OF STATE ASSOCIATION AT THE TIME OF THEIR DEATH

Joseph T. Asbury, Rochester. Born 1875. College of Medicine of the University of Illinois, 1902. Died July, 1929. Age 54.

Joseph E. Campbell, Melrose. Born 1853. Died March, 1930. Age 77.

Daniel C. Darrow, Crookston. Born 1850. Died Jan. 10, 1930. Age 80.

John Ekrem, Gully. Born 1866. Minneapolis College of Physicians and Surgeons, 1903. Died May, 1930. Age 64.

Lorenzo A. Gray, Fairmont. Born 1899. Died Feb. 27, 1930. Age 31.

Henry F. Hoyt, Long Beach, California. Born 1854. Rush Medical College. Died Jan. 21, 1930. Age 76.

Ethel Hurd, Minneapolis. Born 1846. University of Minnesota, 1897. Died Aug., 1929. Age 83.

E. R. Jellison, Minneapolis. Michigan, 1883. Died Jan. 27, 1929.

Hugo H. Miller, Minneapolis. Born 1865. Minneapolis College of Physicians and Surgeons, 1892. Died Sept. 4, 1929. Age 64.

Louis L. Moench, Waterville. Born 1875. Eclectic Medical College, Cincinnati, 1902. Died June 2, 1930. Age 55.

James B. Muir, Roseau. Born 1860. Bennett Medical College, Chicago, 1885. Died Oct., 1929. Age 69.

William B. Murray, Minneapolis. Born 1862. Minneapolis College of Physicians and Surgeons, 1890. Died Aug., 1929. Age 67.

N. A. Nelson, Dawson. Born 1855. King Eclectic Medical College, 1884. Died Sept., 1929. Age 74.

Francis M. Prettyman, Northfield. Born 1850. Died Feb. 13, 1930. Age 80.

James A. Rippert, Duluth. Born 1886. College of Physicians and Surgeons, Baltimore, 1910. Died July, 1929. Age 43.

C. L. Schneider, Deer Creek. Born 1873. Wisconsin College of Physicians and Surgeons, 1902. Died Sept., 1929. Age 56.

Samuel M. Stocker, Fergus Falls. Born 1857. New York University Medical College, 1885. Died Nov., 1929. Age 72.

P. A. Walling, Park Rapids. Born 1850. University of Buffalo, 1876. Died May, 1929. Age 79.

Charles W. Watson, Minneapolis. Born 1867. Minneapolis College of Physicians and Surgeons, 1897. Died May, 1930. Age 63.

George O. Welch, Fergus Falls. Born 1860. Boston University, 1887. Died June, 1929. Age 69.

George J. Wilson, Moorhead. Born 1835. Died Sept., 1929. Age 94.

E. W. Young, Minneapolis. Born 1852. Minneapolis College of Physicians and Surgeons, 1896. Died Feb. 19, 1930. Age 78.

Benjamin M. Randall, Graceville. Born 1858. Rush Medical College, 1883. Died May 24, 1930. Age 72.

Some had carried the honored name of physician but a few years of their youth, some through the many years of their maturity. To each is applicable the kindly description of the ancient poet, "It was his part to learn of the power of Medicine and of the manner of healing, and, heedless of Glory, to exercise that quiet art" (Virgil).

OLGA S. HANSEN, *Necrologist.*

PRESIDENT BOYER: We will now stand with bowed heads for a moment in memory of our departed brethren.

The audience arose and stood in silence.

DR. MANLEY: Next is the report of the Historical Committee.

REPORT OF HISTORICAL COMMITTEE

Your historical committee desires to submit the following report. On three previous occasions, the committee has outlined its program for future activities, given the chapters under which the history is being prepared, told something of the search for material and reported the progress already made in different directions. It seems hardly necessary to repeat these statements.

Additional items of information are continually being brought to our attention and we wish particularly to express our appreciation on account of material relating to the very early physicians in this territory, obtained through the State Historical Society.

The task of putting the facts at our disposal into some sort of literary form is proving even greater than that involved in the original search for material and we are now informed that it will probably require quite one year for publication, even after the manuscript is complete.

In view of the above, the committee looks with some skepticism on its earlier somewhat rosy prognosis as to an early date of publication.

In the interim, the committee desires to call attention to what it considers an injustice done the pioneers who founded the first medical society in 1853. On July 23, of that year, sixteen medical men of the territory (Drs. Thos. R. Potts, James D. Goodrich, W. W. Finch, John J. Dewey, and T. T. Mann, of St. Paul; John H. Murphy and Charles L. Anderson, of St. Anthony Falls; A. E. Johnson, St. Anthony City; and Alfred E. Ames, Hennepin County, were actually present. Drs. A. W. Daniels, of St. Peter; MacDougall, of Fort Snelling; C. Carli, of Stillwater; and P. P. Marsh, J. H. Day, A. G. Brisbine and Samuel Willey, all of St. Paul, were made charter members on account of interest previously expressed in the organization) met in St. Paul and assisted in the organization of the Minnesota Medical Society. This is substantiated by the report in the lay press of that date (the St. Anthony Express, Vol. III, No. 10, July 30, 1853) and by a note in the Boston Medical and Surgical Journal, Oct. 12, 1853, from Dr. William W. Finch, of St. Paul. Officers were elected, committees appointed and a constitution and by-laws adopted. There is reliable evidence that subsequent meetings were held in 1856 and in 1867 and it is probable that still other meetings were held. Subsequently the society languished and finally ceased to function during the Civil War and up to 1869.

On Feb. 1, 1869, a meeting of the physicians of Minnesota was held in St. Paul. Considerable time was spent in discussing the question of whether they were reviving a preëxisting society or forming a new organization. The final action taken certainly endorsed the idea of forming a new society but a careful survey of the minutes of the meeting suggests little basis for the contention that a really new society was formed.

At this meeting of 1869, it was accepted that a "Minnesota State [?] Medical Society" had been formed in 1855. Though both name and date are incorrect, this obviously referred to the old society. In any reference to the society, found between 1853 and 1869, Dr. Thomas R. Potts, of St. Paul, appears as the President and Dr. John H. Murphy, of St. Anthony Falls, as the Vice President, and these two were accepted, by virtue of their previous positions, as the presiding officers of the new assembly. The Board of Censors of the old organization served in the same capacity for the new organization and proposed a list of names of those duly qualified for membership, which list was accepted. Even the old Constitution and By-Laws were adopted with no change except as to the date of meeting.

The Hennepin County Medical Society passed through a practically identical experience. On June 20, 1855, a society known as the Union Medical Society of St. Anthony and Minneapolis was organized at the home of Dr. A. E. Ames, in Minneapolis. Very much as the territorial and state organization had done, it struggled through the Civil War period with only occasional meetings. In March or April of 1869, it was renamed the Hennepin County Medical Society and in June of 1870 it was reorganized. Notwithstanding these changes in its name, its periods of service and its reorganization, the Hennepin County Medical Society has never hesitated to consider its birth date as June 20, 1855.

Considering, then, that a medical society was actually formed in Minnesota Territory in 1853, that it functioned more or less well as a pioneer organization to 1869, that the old officers held over even into the organization of the new society, controlling the methods of procedure and even censoring the names of applicants for admission and considering that the old Constitution and By-Laws were adopted without essential alteration, it is the opinion of your committee that these societies, practically alike in name, serving the same communities, actuated by the same principles, having the same officers and operating under the same Constitution and By-Laws, should be considered as one society and that the date of our founding be accepted as July 23, 1853.

A. S. HAMILTON, M.D., *Chairman.*

ADDENDA

It seems that the necrologist of this society could well be a member of the Historical Committee delegated by the chairman to tabulate the necrology reports. The work of the two committees overlaps and it would seem that the necrologist may be of some assistance in the collection of historical material.

DR. MANLEY: This is a very complete and comprehensive report, and the Reference Committee wishes to commend the Historical Committee. We also recommend the adoption of a resolution making the Necrologist of this Society a member of the Historical Committee. We also recommend, and I move, that the report be accepted.

PRESIDENT BOYER: Bear in mind that the recommendation to place the Necrologist on the Historical Committee really has to be accomplished by way of an amendment to our by-laws. It is needless to state that as a member of the Historical Committee the necrology reports will be handed in by way of that committee. Is there any further discussion?

DR. WORKMAN (Tracy): The first President of this Society was Dr. Potts. He was elected in 1853. The Society didn't meet every year, but along about the time of the Civil War members ceased to meet; they met again with Dr. Potts in the chair. They adopted the old by-laws and the old organization name and all, but in the reorganization they appointed a committee on credentials. In the written minutes this committee was appointed to eliminate certain men that were very irregular. It shows that in 1869 there were more irregular physicians in Minnesota than there were regulars, and that was one way of getting rid of them. That is why I move the adoption of 1853 as the year of the birth of this organization, and this would be the seventy-seventh meeting, and I make that as a motion.

Motion was carried.

PRESIDENT BOYER: As the acceptance of this report implies the amending of the by-laws, Dr. Coventry will write an amendment in conformity therewith.

DR. COVENTRY: Here is the amendment:

"RESOLVED, That Chapter IX, Section I, be amended by striking out the words 'A committte on Necrology' and that the duties of this committee be transferred to the duties of the Historical Committee."

A motion was made and carried that the report of the Historical Committee be accepted.

PRESIDENT BOYER: The Reference Committee.

DR. MANLEY: The report of the Radio Committee, Dr. S. R. Maxeiner, Chairman.

REPORT OF THE RADIO COMMITTEE

One hundred seventeen radio programs were broadcast under the direction of the Radio Committee from April 3, 1928, to June 1, 1930. With the exception of two programs from KSTP, all have been sent from Station WCCO.

The regular health service feature has been given every Wednesday morning at 10:15 with the exception of holidays by Dr. Wm. A. O'Brien, Associate Professor of Pathology, University of Minnesota. A list of the subjects follows: (1) The Modern Health Problem, (2) Well Balanced Diet, (3) Fresh Air, (4) Rest and Sleep, (5) Prevention of Diphtheria, (6) Typhoid Fever, (7) Maternal and Infant Hygiene, (8) The Goiter Problem, (9) Care of Wounds, (10) Rabies, (11) How We Breathe, (12) Diseases of the Liver, (13) Outlook for Young Diabetics, (14) Circulation of the Blood, (15) Vitamines, (16) How the Well Can Help the Sick, (17) What Is a Neurotic? (18) How We Hear, (19) The Cause of Cancer, (20) Cathartics and Appendicitis, (21) Factors in the Health Problem, (22) Cancer of the Stomach, (23) Correcting Nature's Mistakes, (24) Cause of Anemia, (25) Getting the Children Ready for School, (26) Heat Stroke and Exhaustion, (27) Obesity, (28) Cancer of Breast and Uterus, (29) Foreign Bodies in the Lungs, (30) Paralysis and Will Power, (31) Conquest of Tuberculosis, (32) Influenza, (33) Gas Poisoning, (34) Children and Tuberculosis, (35) Why We Worry, (36) Physical Activity, (37) What Is Arthritis? (38) Tularemia, A Disease of Man and Animals, (39) The First Year, (40) Fish as a Food, (41) Burns, (42) Ultra-Violet Rays, (43) Gallstones, (44) Care of the Feet, (45) What the Modern Hospital Means to You, (46) Problems of Maturity, (47) Fractures, (48) Varicose Veins, (49) Emotional Instability, (50) High Blood Pressure, (51) Medical Superstitions, (52) Mucous Colitis, (53) Hay Fever, (54) Ulcer of the Stomach, (55) Inflammation of the Middle Ear, (56) Prevention of Heart Disease, (57) Pasteurized Milk, (58) Adopting a Baby, (59) Rheumatic Heart Disease, (60) Ptomaine Poisoning (A Myth), (61) Eczema and Dermatitis, (62) First Aid, (63) Small Town Health Problems, (64) Fumigation, (65) Prevention and Early Treatment of Disease, (66) Hot Weather and Health, (67) How Long Will You Live? (68) Modern Treatment of Tuberculosis, (69) Babies in Hot Weather, (70) Need for a Psychopathic Hospital, (71) Diseased Tonsils and Adenoids, (72) Undulant Fever, (73) Cancer Facts, (74) Heart Pains, (75) Advances in Public Health, (76) Tetanus, (77) Catarrhal Deafness, (78) Pellagra, (79) Diseases of Allergy, (80) Story of Muscle, (81) Care of Feet and Legs in Diabetes, (82) Fall and Winter Babies, (83) When Deafness Comes, (84) Cirrhosis of the Liver, (85) Blue Ribbon Children, (86) Cause of Headaches, (87) Carbon Monoxide, A Menace, (88) Disseminated

Sclerosis, (89) Anesthesia, The Great Gift, (90) Cause and Prevention of Bunions, (91) Health and Safety, (92) Infantile Paralysis, (93) Preventable Blindness, (94) Pork Worm Disease, (95) Glaucoma, (96) Feeding the Problem Child, (97) Treatment of High Blood Pressure, (98) Dangers of Self-Medication, (99) Cause of Bronchitis, (100) Facial Paralysis, (101) Cancer Cures, (102) White Versus Brown Bread, (103) Safeguarding Motherhood, (104) Code of Medical Ethics, (105) Inflammation of the Mastoid, (106) Christmas Seal, (107) Measles.

In addition to the regular Wednesday morning feature from WCCO, the following programs have been sponsored: (108) Cosmetic Nostrums, Dr. Arthur J. Cramp, American Medical Association, (109) American College of Surgeons, David Jolly, Houston, Texas, (110) Periodic Health Examinations, Dr. W. D. Haggard, Nashville, Tenn., (111) Keeping Fit, Mr. A. R. Jones, Gorgas Memorial, (112) Teen Age Problems, Dr. W. A. O'Brien, Hennepin County T. B. Association, (113) Pre-School Child, Dr. W. A. O'Brien, Federation of Women's Clubs, (114) Installation of President American Medical Association, (115) Visiting the Sick, Dr. W. A. O'Brien, Minnesota State Hospital Association, (116) New Childhood, Dr. W. A. O'Brien, Minnesota Public Health Association, (117) Problems of Tuberculosis, Dr. F. M. Pottenger, American College of Physicians.

Censorship.—Station WCCO volunteered to turn over the problem of passing on all medical advertising to the Committee. Since then, nothing has appeared on the air from WCCO of objectionable nature, because of this arrangement. There was one program which was approved and later proved to be objectionable. This was because of misrepresentation on the part of the advertiser, and the station regrets it just as much as we do.

Publicity.—Good publicity has been received from all the papers and the station. Announcements of the programs appear in the press and are given over the air at frequent intervals. In addition, since January 1, 1930, all programs have been made in advance and are now published in Minnesota Medicine. More recently they have been carried by the Journal-Lancet and some of the newspapers. Everybody's Health now carries "Health from the Air" extracts from the programs since May 1, 1930.

Audience.—We are still reaching the state of Minnesota, parts of North and South Dakota, Iowa, Wisconsin, and northern Michigan. We have been informed that our audience has grown to a remarkable size and that the health service feature is now one of the main attractions of WCCO. Letters from interested listeners vary from four to three hundred per talk. When the audience is promised a copy of the talk, a large number write in; otherwise, few letters are received except those asking for advice and offering suggestions for future programs. As the program is part of the Women's Hour feature of the station, naturally, a large percentage of our audience is women. We believe this is very desirable as it is through the women that we reach the home and family. The number of convalescents, invalids, and shut-ins remains about the same. They have been very much interested in the talks and write frequently.

Our letters also indicate that a large number of men are now listening. This is very desirable, and the number could be increased by an evening feature. Many persons ask why we do not broadcast in the evening when they can remain at home and listen. It seems best at the present time to concentrate on the morning hour as we get a very desirable audience in this way, desirous of instruction. When the programs were first started, the station told us that if it was a success future prorgams could probably be arranged at different time. The Committee feels that it is now opportune for us to think about developing an evening feature as well.

The number of physicians who listen to the programs is probably not very great. This is undoubtedly due to the fact that the programs come in the morning when most doctors are busy; however, many doctors have written to assure us of their interest and hearty cooperation and state that they make a special effort to listen in to learn what the people are being taught. Any way that we could develop this feature would be most desirable, because it is felt that the suggestions we are making to the public should be known to the doctors.

The air is polluted at the present time with all sorts of quackery, and it is only through our service that we will be able to meet this form of opposition. Many of the other stations carry objectionable advertising programs, but it is very difficult to know what to do about it, as jurisdiction over this matter comes from two sources—the Federal Trade Commission and the Federal Radio Commission. The action of the American Medical Association on objectionable medical advertising is being watched with interest, and it will probably point the way to more effective censorship on the part of your Committee.

We wish to thank Station WCCO particularly for the splendid coöperation we have received. If we had to pay regular advertising rates for our time, it would have amounted to thousands of dollars. The Station has very gladly donated this because they appreciate that our Association is attempting to do a very worth while piece of work. It is now believed that we have over one million weekly listeners, and many of them listen with regularity. We are now entering on our third year of broadcasting and believe that the future holds still greater possibilities in store for us. The Committee feel that the service has been a marked success and urge that it be continued.

S. R. Maxeiner, M.D., *Chairman.*

Dr. Manley: The Radio Committee has done an immense amount of valuable work, and we wish to commend the work of this committee. We also wish to ask the House of Delegates to give Dr. O'Brien a vote of thanks for his radio health talks with which we are all familiar. He now has an immense audience and this is undoubtedly one of the most valuable methods of reaching the public which can be adopted.

The report of the Radio Committee was voted upon and accepted.

President Boyer: We would like to hear from Dr. O'Brien.

Dr. O'Brien (Minneapolis): We feel that we have gained ground the past year as we did the year before. We are adding new friends, and it was a pleasure to walk around the lobby today and to meet so many doctors who told me so many of their patients have been listening in and getting beneficial results from the talks. In addition to the women we are getting a large number of men who are now listening in. Because we have received so few criticisms in the past I am afraid not many doctors are listening, because if they were we would be getting letters stating that they did not like some of the things we said. I wish to state that at five o'clock this afternoon the Radio Committee will be talking over WEBC, Duluth. I thank you. (Applause.)

Dr. Manley: Report of the Committee on Hospitals and Medical Education, Dr. Pearce, Chairman.

REPORT OF THE COMMITTEE ON HOSPITALS AND MEDICAL EDUCATION

June 1, 1929, to May 31, 1930

Your Committee has been working in the past year much along the lines of the program that has been under way for the past several years. The three major activities of the Committee are the Extension Courses, the Colloquium Lecture Series, and the Consultation Bureau.

More Extension Courses have been carried on this year than ever before. It is unnecessary for me to repeat that these Extension Courses are a joint enterprise of the State Medical School, the State Medical Association, and the Extension Division of the University of Minnesota.

The Colloquium Lecture Series is not very different from the regular Extension Course except that it is designed to reach new groups whom we have been unable to interest in the regular courses. Also, in a general way, these courses were designed to correlate the programs of the State Medical Association, the Medical School, the State Board of Health, the Minnesota Public Health Association, and the University Hospital, and furnish an opportunity for these organizations to meet with the practicing physicians of the state. Five of these courses which were offered were quickly subscribed to, in three instances in places where we have never before been able to interest the men in an extension course. More of these courses will probably be offered this fall.

The demand on the Consultation Bureau has been growing slowly. There was a marked increase in interest after the blotters were sent out by Dr. Meyerding. The facilities of this Bureau are without doubt a most valuable source of prompt and reliable confidential information, and we believe in time will prove to be one of the greatest contributions of the State Association to its members. We should express our appreciation of the help and interest of the men who have so freely given their time in helping the Bureau answer the many queries, and to the physicians who have shown the same interest in sending them in.

Dr. O'Brien, the Director of the Bureau, expects to be able to show you a map designating the extension of the use of these services.

Attached to this summary of the report you will find a detailed account of the activities of the Consultation Bureau, the Extension Courses, and a brief outline of the work of the Colloquium Lecture Series which were given this spring at Wadena, Willmar, Litchfield, Faribault, Brainerd, and Winona.

Respectfully submitted,

N. O. Pearce, *Chairman.*

CONSULTATION BUREAU

March 21, 1929, to Sept. 20, 1929

Organized March 21, 1929.

First inquiry received within 24 hours after announcement; 55 inquiries have been received to September 20, 1929.

Types of inquiries received are as follows:

Case Reports—29; requesting general information, 5; requesting prognosis, 1; requesting diagnosis, 4; requesting treatment, 10; requesting diagnosis and treatment, 7; reading of dental films, 1; question of industrial disease, 1.

Publications—Books to buy, 3; where to publish articles, 1.

Apparatus and Appliances—3.

Medico-Legal—4.

Locum Tenens Appointment—2.

General—Treatment of diseases, 3; courses of study, 2; reliability of radium corporation, 1; state aid for charity patient, 1; patent medicine, 2; drugs, 1; therapy, 1; blood test to prove paternity, 1; use of Schick Test, 1.

Four cases were followed up by further inquiry.

Thirty-nine doctors have used the service.

Eleven doctors have sent in from two to four inquiries.

Number of inquiries received, according to month: March, 1929, 6; April, 1929, 15; May, 1929, 10; June, 1929, 6; July, 1929, 6; August, 1929, 6; September, 1929, 5.

Sept. 20, 1929, to May 20, 1930

Types of inquiries received are as follows:

Case Reports—66; requesting general information, 11; requesting diagnosis, 12; requesting prognosis, 4; requesting treatment, 26; requesting reading of dental films, 1; requesting reading of *x*-ray pictures, 1.

General—Information regarding schools, 1; information regarding books, 4; blood test to prove paternity, 2; patent medicine, 1; drugs, 1.

Medico-Legal—1.

Forty doctors have used the service.

Eleven doctors have sent in from two to six inquiries.

Number of inquiries received, according to month: October, 1929, 7; November, 1929, 4; December, 1929, 5; January, 1930, 7; February, 1930, 5; March, 1930, 3; April, 1930, 20; May, 1930, 15.

EXTENSION COURSES

June 1, 1929, to May 31, 1930

Olivia—April 19 to May 10, 1929; 18 registrations; 4 lectures; cost $70.00. Lecturers: Drs. Moses Barron, G. B. Eusterman, T. W. Weum, E. D. Anderson.

Willmar—May 23 to June 27, 1929; 14 registrations; 6 lectures; cost $75.00. Lecturers: Drs. C. N. Hensel

T. B. Hartzell, H. Z. Giffin, K. Bulkley, P. W. Giessler, E. M. Hammes.

Fulda-Worthington—September 3 to October 22, 1929; 35 registrations; 5 lectures; cost $112.50. Lecturers: Drs. E. Bannick, A. F. Bratrud, E. T. Evans, T. W. Weum, G. N. Ruhberg.

Olivia—September 16 to November 11, 1929; 20 registrations; 8 lectures; cost $75.00. Lecturers: Drs. J. F. Fulton, A. H. Beard, C. N. Hensel, E. T. Herrmann, C. B. Wright, Rood Taylor, E. C. Robitshek, S. R. Maxeiner.

Houston-Fillmore County Society—September 27 to October 24, 1929; 12 registrations; 3 lectures; cost $35.00. Lecturers: Drs. E. G. Bannick, H. I. Lillie, J. M. Hayes.

Marshall—October 1 to November 5, 1929; 25 registrations; 6 lectures; cost $135.00. Lecturers: Drs. J. M. Hayes, W. A. Jones, Z. Giffin, Moses Barron, O. H. Wangensteen, H. E. Michelson.

Hibbing—October 3 to November 21, 1929; 20 registrations; 7 lectures; cost $150.00. Lecturers: Drs. H. E. Michelson, E. M. Hammes, A. F. Bratrud, F. J. Hirschboeck, B. F. Davis, J. R. Manley, O. W. Rowe.

Mankato—October 10 to December 19, 1929; 25 registrations; 10 lectures; cost $160.00. Lecturers: Drs. F. C. Rodda, W. C. Alvarez, A. R. Barnes, P. S. Hench, Horace Newhart, C. N. Hensel, N. M. Keith, A. M. Snell, B. S. Gardner, L. A. Buie.

St. Cloud—December 12, 1929, to March 6, 1930; 20 registrations; 12 lectures; cost $96.00. Lecturers: Drs. C. N. Hensel, R. C. Logefiel; W. A. Fansler, R. T. LaVake, Fred Pratt, H. O. Altnow, E. A. Loomis, H. E. Michelson, W. E. Camp, G. R. Dunn, Moses Barron. (Dr. Altnow gave three different lectures in the series.)

Hibbing—April 3 to May 8, 1930; 17 registrations; 6 lectures; cost $160.00. Lecturers: Drs. F. J. Hirschboeck, Franklin R. Wright, A. B. Rivers, J. R. Kuth, H. G. Irvine, W. A. Fansler.

Mankato—April 3 to June 12, 1930; 25 registrations; 10 lectures; cost $160.00. Lecturers: Drs. E. T. Evans, H. M. Connor, E. T. Herrmann, H. B. Sweetser, Jr., E. G. Bannick, T. W. Weum, E. J. Huenekens, W. H. Goeckermann, Walter Camp, and one not yet assigned for the last meeting.

Marshall—April 8 to May 27, 1930; 18 registrations; 8 lectures; cost $185.00. Lecturers: Drs. W. E. Patterson, P. A. O'Leary, R. T. LaVake, F. C. Rodda, C. N. Hensel, L. A. Buie, C. C. Chatterton, V. S. Counsellor.

Willmar (colloquium)—April 17 to June 5, 1930; number of registrations not known; 8 programs; cost $50.00. Cost to General Extension Division $55.00 (estimated).

Brainerd (colloquium)—April 21 to June 9, 1930; number of registrations not known; 8 programs; cost $50.00. Cost to the General Extension Division $72.00 (estimated).

Olivia—April 21 to June 9, 1930; 12 registrations; 8 lectures; cost $85.00. Lecturers: Drs. E. T. Evans, R. C. Logefiel, H. E. Michelson, R. C. Webb, F. C. Rodda, Horace Newhart, R. S. Rizer, and probably A. M. Snell.

Winona (colloquium)—April 22 to June 10, 1930; number of registrations not known; 8 programs; cost $50.00. Cost to the General Extension Division $65.00 (estimated).

Wadena (colloquium)—May 2 to June 27, 1930; number of registrations not known; 8 programs; cost $50.00. Cost to the General Extension Division $80.50 (estimated).

Faribault (colloquium)—May 5 to June 23, 1930; number of registrations not known; 8 programs; cost $50.00. Cost to the General Extension Division $80.00 (estimated).

A SERIES OF COLLOQUIUM LECTURES

Given at Wadena, Willmar, Litchfield, Faribault, Brainerd, and Winona.

A Post-Graduate Medical Short Course of unusual interest is offered to the members of the Minnesota State Medical Association. A program covering eight weeks at a total expense of only $50, payable to the University Extension Division. This course will consist of the following eight programs, two of which are selected from the regular post-graduate short course list.

Lecture No. 1—Minnesota State Medical Association Meeting

The Women's Auxiliary or your wives may attend. At least three of your state officers will be present. Your state president has promised to attend. The Chairman of the Committee on Hospitals and Medical Education, and the Councilors will be the speakers. The subjects to be discussed will be the affairs of the State Medical Society, its activities, and its relation to the practice of medicine.

Lecture No. 2—"Tuberculosis"—Under the Auspices of the Minnesota Public Health Association

The new phases of Childhood Tuberculosis and Lung Tuberculosis will be discussed and illustrated with movies and lantern slides. Speakers to be selected.

Health Meeting: Arrangements can be made with the local Parents-Teachers Association or other organizations for a Health Meeting. The speakers who appear before the medical group will also be available to speak before a lay group on health subjects. Both meetings can be in session at the same time.

Lecture No. 3—"Cancer," "Obstetrics," "Your Hospital"—Under auspices of the University Hospital and Medical College, University of Minnesota.

Lecture No. 4—Speaker and subject to be selected.

Lecture No. 5—"Heart Disease"—Under auspices of the State Medical Association, Heart Committee.

Lecture No. 6—"Immunology, Toxin Anti-Toxin," and other State and local health problems, under auspices of Minnesota Department of Health.

Lecture No. 7—Speaker and subject to be selected.

Lecture No. 8—Under the auspices of University Extension Service, to be selected from the following:

"Uniform Mental Endowment"—Dr. Herbert Sorenson.
"British and American Humor"—Dr. Herbert Eaton.
"Speech Defects"—Dr. Bryng Bryngelson.
"Art"—Mr. S. Chatwood Burton.
"Insects and Human Affairs, or The Battle with the Bugs"—Dr. Royal Chapman.

Dr. Manley: The Reference Committee recommends the adoption of this very excellent report and wishes to recommend that after the various extension lectures and colloquium courses a report be sent to the chairman of this committee by the local men informing of the success of the meeting from the standpoint of the local society.

A motion was made and carried that the report of the Committee on Hospitals and Medical Education be accepted.

Dr. Pearce (Minneapolis): I haven't very much to add to the report. I simply would say that the chairman of the committee would appreciate any criticism either good or bad from the men who are taking these courses. I might say briefly that our regular extension course plan has seemed to be increasingly in demand each year, and the work of the Consultation Bureau, of which Dr. O'Brien is the head, also seems to be growing. The new colloquium work which has been put on this spring more or less as an experiment, we do not know yet how well they are received and whether they are now put on in the best possible way. We hope, by studying the results this spring, to make changes to improve them. We will at least put on three or four this fall. This lecture series has been the means of reaching into three new districts which we would never have been able to reach with our regular extension courses. Of course, the regular courses will be carried on as usual.

Dr. Robbins (Winona): I was chairman of the committee that was asked to take on these lectures in Winona, and I took charge of the publicity part and Dr. Steiner carried on the rest of the work. We had a committee of two to carry it out, but we had very little time to prepare. I think Dr. Meyerding came down one week and the following week we started our lectures. We averaged thirty attendance of doctors. The lectures were very interesting and instructive and as a general average everybody was enthusiastic about it. We had a territory of sixty doctors to reach within forty miles of Winona, and we believed that our first attempt of getting half of them to the lectures was well worth our efforts.

President Boyer: If there is approval of this thing it is incumbent upon the delegates from the different component committees to carry home a distinct impression of this committee. This committee operates under considerable expense, as is the case with some other committees. You should express yourselves, as some way favorable or opposed to this sort of work.

Dr. Adams (Hibbing): We gave the first course last fall. One doctor came about eighty miles, and one doctor came about sixty miles, and neither missed a single meeting. We are arranging for a third course this fall, and we have found it is not only a good educational proposition but is a good feature to get the doctors together. We have no other sort of contact and this has brought us together, and we have also preceded our evening course with a supper and the fellows enjoyed it very much, and I would recommend to those who have not started it that it be done.

Dr. Manson (Worthington): We have had three courses and are so enthusiastic that we are planning another course this fall. Some of them come for forty miles, and out of a membership of about 52 we had an average attendance of 35 to 38, and we feel that from the standpoint of benefit to the doctor the benefits are two-fold—keeping up to date, and the personal contact that comes from getting together in these meetings.

President Boyer: You have heard from Dr. Manson in the southern part of the state and from Dr. Adams in the northern part of the state, telling of the advantages of this work. Are there any other remarks?

We will hear from the Reference Committee.

Dr. Manley: The Reference Committee recommends the adoption of the report of the Heart Committee. This is a very important committee and the report should be read carefully by all the delegates. We also recommend that this report be specially featured in Minnesota Medicine, and that the committee continue the excellent work which they have started.

REPORT OF THE HEART COMMITTEE

Since the last report there have been some additional developments in the Heart Committee which might be of interest to your body. In the latter part of November, 1929, a notice was received from Dr. J. A. Myers, President of the Minnesota Public Health Association, stating that the Minnesota Public Health Association had been appointed by the American Heart Association as its official representative in the state of Minnesota. It was the belief of the Minnesota Public Health Association that this affiliation was demanded because the situation in this state was becoming rather acute as far as the control of the public health campaign was concerned. A Heart Committee of the Minnesota Public Health Association was then appointed with Dr. J. A. Myers as chairman and with a total membership of nine, all physicians and two of them members of the Heart Committee of Minnesota State Medical Association, Dr. F. A. Willius and Dr. F. J. Hirschboeck.

The precedent for an affiliation with the Public Health Association has been established in certain states, notably Wisconsin, Iowa, Pennsylvania and New York. It is proposed by the Public Health Association Committee to coöperate fully with the Heart Committee of the Minnesota State Medical Association and to have the latter serve as a liaison committee with the State Medical Society and for the purpose of approach to the practitioners of the state. It is hoped that by means of this affiliation some of the funds at the present time derived from the sale of Christmas Seals may be employed in the furtherance of the campaign regarding heart disease much as it has been used in the past concerning tuberculosis.

It is the wish of the Heart Committee of the Minnesota State Medical Association that the educational work at the present time be restricted to educating the physicians of the state by means of lectures, heart symposia, colloquium courses and use of a short period in each regular program for consideration of a cardiologic subject and to do everything possible to prepare the men in practice in properly conducting heart clinics and to interest themselves in the rehabilitation of chronic cardiopaths and education on the prevention of breakdowns in later years. In order to exert influence on this movement medical men of the state must interest themselves in the broad sociologic and economic phase of the subject and prepare themselves in cardiology so that they will be able to undertake any work requested of them lest it fall into the hands either of restricted specialists as the work in tuberculosis is at the present time or into the hands of a lay body as is the situation in Ohio presently, in which the medical profession is entirely ignored.

We believe that at the present time as the Heart Committee is organized, and with a spirit of *rapport* between the State Medical Society and the Public Health Association, much can be achieved on the one hand in bringing about a higher standard in the knowledge of cardiology among the practitioners in the state and on the other hand prevent an abuse that might tend ultimately to cleave out another large segment of practice from the general practitioner.

As a result of this educational program there have been five discussions on a cardiologic subject in various sections of the state as a part of the Colloquium course sponsored by the committee of Medical Education under Dr. N. O. Pearce, namely at Wadena, Willmar, Faribault, Brainerd and Winona. The St. Louis County Medical Society devotes ten minutes of every monthly meeting to a consideration of cardiologic subjects and a circular letter written to the secretaries of the component societies of the state urging this plan has elicited a favorable response from several. It is suggested that this movement be continued and that other sections of the state take up the Colloquium course in order to foster the educational work within the profession. At the present time the Hennepin County Medical Society has a County Heart Committee which works in conjunction with the Minnesota Public Health Association in promoting occupational placement of chronic cardiopaths and in the establishment of cardiologic clinics and has prepared an excellent course on cardiology which was given at thirteen successive noon meetings of the Hennepin County Medical Society at their club rooms. It is further proposed this next year, beginning in the fall, to have a series of articles in Minnesota Medicine, permission for which has been tentatively granted by Dr. C. B. Drake, giving a serial, comprehensive outline of cardiology for educational purposes in the profession and for the standardization and classification of vital statistics on that phase of practice.

F. A. Willius — A. D. Hoidale
H. E. Richardson — D. P. Head
H J. Lloyd — F. J. Hirschboeck, *Chairman*

A motion was made and carried that the report be accepted.

President Boyer: Gentlemen, the American Heart Association some time ago took up the matter of heart study and heart education, seeking to disseminate knowledge of heart disease among the public. It becomes incumbent upon us as the profession to see that we ourselves are better informed on this matter than the public. This report should be published in Minnesota Medicine—not only that, but the report should be sent as a letter to every member of the State Society.

The Reference Committee.

Dr. Manley: The report of the Committee on State Health Relations, Dr. Sweetser, Chairman.

REPORT OF THE COMMITTEE ON STATE HEALTH RELATIONS

Up to June 1, one stated meeting was held and there were numerous informal meetings of parts of the Committee. Contact has been maintained with the State Board of Health and other tax-supported health agencies and with the Committee on Public Health Education. Various letters referred to the Committee from the State Board of Health have been cared for on the principle that the work of preventive medicine should be done as much as possible by physicians as part of the private practice of medicine, and that the conditions governing any coöperative medical work should be determined by the local county or district medical society.

Last year, at the instance of your Committee, the House of Delegates recommended that each local Medical Society set up a scale of fees for public health work. We are trying to find out the present status in that regard.

Last year the Committee supported the previous recommendation of the Committee on Public Health Education that each local society establish a public welfare committee to maintain contact with and influence the medical policies of various local health agencies. We are trying to find out which local medical societies have such committees.

The Committee has endeavored through the year to help where possible in the campaign for immunization against diphtheria.

Theodore H. Sweetser, M.D., *Chairman.*

Dr. Manley: This is one of the most important committees in the Society and they have done a great deal of work. The Reference Committee recommends the adoption of this report, and would ask the delegates if they can make any answer or report on two questions which this committee brought up last year: First, have any local medical societies set up a scale of fees for public health work? Second, has each local society a public welfare committee to maintain contact with and influence the medical policies of various public health agencies?

Motion was made and carried that the report be adopted.

Dr. Sweetser (Minneapolis): Last year, on the basis of the report of the Committee on State Health Relations, the House of Delegates recommended that each

local society (1) adopt a scale of fees for official public health work done by its members, and (2) appoint a public welfare committee to maintain contact with and influence the medical policies of the various official and unofficial local health agencies. We have recently asked the Secretaries of the local societies as to what action has been taken. Twenty out of the thirty-four Secretaries replied in each instance that nothing has been done. I hope that, when you go home, you will do your best to have some action taken, as I feel that both these matters are of importance.

The public is very much interested, as you all know, in matters of public and personal health. Requests have repeatedly been sent to the State Board of Health requesting wholesale vaccinations and diphtheria inoculations. Dr. Chesley has referred these requests to us and the people have been advised to make arrangements with their local physicians individually or through their County Medical Society. One such request gave evidence that the writer wished the State Board of Health rather than the private physician to do the work in order to get something for nothing. In another instance, however, it was evident that some coöperative work by the physicians of a District Medical Society would be necessary if the work were to be done as part of the private practice of medicine. It seems to me that everyone in the private practice of medicine must take a more active interest in community health matters if such matters are to be kept within the scope of private practice and not forced into the hands of the official and unofficial health agencies.

PRESIDENT BOYER: Is there any further discussion of the question of the work of Dr. Sweetser's committee?

The Reference Committee.

DR. MANLEY: The next is the report of the most important committee of the whole society, the Committee on Public Policy and Legislation. The chairman of this committee, Dr. Johnson, requests that he be allowed to give his report orally.

DR. JOHNSON (Dawson): We have had a great deal of trouble with national legislation this year, not that we have made so much noise about it, but there is one thing after another. You might class them under the heading of the Sheppard-Towner legislation and the narcotic bills. We have wired and written our different congressmen about these bills. We got Dr. Wright, on his way East, to go to Washington to see the Minnesota congressmen in regard to them. Under the bills introduced The Children's Bureau would have taken the control right out of the hands of the state and would have given all authority to some Laymen's Bureau in Washington, who would be absolutely independent of any medical organization, and State Board of Health, or the United States Public Health Service. If this is going to be handled at all in a national way, it should be handled through our Public Health Service at Washington. In spite of our best efforts, these paid-up lefters will probably keep at it until they get some kind of a bill through Congress.

The next thing is the narcotic bills. There have been two or three different types of them. One bill would have given absolute control to some bureau in Washington and they would have been responsible to no one. For any infraction of their regulations, they could revoke our license to practice medicine and we would have to go to Washington to fight it. This was a hard fight and a great deal of effort was spent in defeating it.

Dr. Wright introduced a resolution in the House of Delegates of the American Medical Association which provided that the Board of Trustees appoint a committee of five to study national legislation. Dr. Braasch, as a member of the committee to which this resolution was referred, did a great deal to secure for it a recommendation to pass. I appeared before the committee in behalf of the resolution and did what little I could to get it passed. It was finally enacted by the House of Delegates and such a committee will now be appointed. The Board of Trustees is very conservative, it seems to us, when it comes to expending money for national legislation. We feel that they are not spending enough money down there and that congressmen don't know everything about these bills. The committee appointed by the Board of Trustees are to report to the next House of Delegates and also to the Board of Trustees such recommendations as they think necessary. Right there in Washington is where the trouble to our profession is coming from in the way of state and social medicine, and that is where it must be fought out. Washington is filled with lobbyists, who are often financed by well-meaning, but misinformed and misguided individuals.

Next take the Veterans' bill. I don't know how many bills have been introduced, but the House of Delegates of the American Medical Association passed a resolution asking the president to veto the Veterans' bill, which he did. Even against this there was a fight in the House of Delegates as some were afraid of offending some one, but finally they came to the conclusion that if they wanted anything they would have to ask for it and fight for it if necessary. By the time we got through, I am sure they all understood what the Minnesota delegation stood for. The resolution went through in fine shape. One of the doctors in charge of an army hospital said that out of six hundred beds in the hospital, eighty-five per cent were occupied by people whose disease had no service connection. If it keeps on as it has and they want more and more Veterans' hospitals, the time will come when these veterans are not going to be hospitalized all the time and these hospitals will be empty. The government is not going to have them empty and some use will be made of them, probably in the line of state and social medicine. It surely will be an opening wedge for some form of state medicine. We are not opposed to taking care of the man who is entitled to it, but we don't believe in treating diseases with no service connection in government hospitals. It was brought up in the House of Delegates that we should work for some system in coöperation with the government, whereby instead of the government building so many hospitals that the veterans be treated in their home cities in the local hospitals, but the government would pay for the hospitalization and medical services.

Don't forget the American Medical Association, because if there ever was a need for organized medicine sticking together, it was never more necessary than it is now. I really feel that the day may come when we would be glad to pay a hundred dollars a year as dues to the American Medical Association and state associations, if by so doing we can stop the trend of things from drifting the way they are now doing.

In regard to our own state, I feel that if we continue to stay active and well-organized as we have in the past few years we can take care of things here. We likely will have problems to fight as usual at the next session. The thing to do is to be ready for them when they come, and be constantly on the job. If we aren't, they certainly will take advantage of the opportunity to pass new quack bills and to repeal legislation passed the last few years.

In closing I want to say that the efficiency of our state organization is, in a large measure, due to our far-seeing and broad-minded councilors and our active president and hard-working committees. Last, but not least, to our own active and able secretary, Dr. Meyerding. What Dr. West is to the American Medical Association, Dr. Meyerding is to our organization. We know that other organizations are offering him greater opportunities and more of a financial reward than he is getting here. We hope he will not leave us, but will stay here. It would be a hard blow to our state association if we should be deprived of his valuable services.

PRESIDENT BOYER: We will hear from Mr. Brist.

MR. BRIST (St. Paul): We have run across two or three things in this state with reference to getting after quacks. The first thing is the naturopath. I started after one in the northern part of the state some time ago, told him who I was and asked to see his Basic Science Certificate. He said he didn't have it. He was a graduate chiropractor from the school of Davenport, and couldn't get a license because he couldn't pass the examination, but belonged to the Naturopathic Society. He was supposed to pay $25.00 but they had been assessed an extra $200.00 every year for the legislature. He said, "Furthermore, I understand there is an agreement with the Medical Board that we will not be prosecuted." He gave me the man's name and I told him he had better go back to his lawyer and find out about the four we had convicted. He said, "We felt you would get tired of fighting us and grant Basic Science Certificates to those of us who were in the state." I told him the chances were very slim, as legislation along this line was very carefully watched by the medical profession and the public. I said I would come back in thirty days and if he was still there he would be arrested for practicing without a license. He said he was going back to Winnipeg.

There is another class of people in Minnesota. There are only six of them that I know of so far who call themselves napropaths. They are from a school in Chicago. One of them is under arrest in this town now. The definition means, "That branch of medicine which attributes disease and disorders to an improper condition and functioning of the ligaments and connecting tissue." Since they returned from their convention in Chicago they have taken down their signs from their doors. One has refused to do it, and the Medical Board has served notice on him to appear next week and show cause why his license should not be revoked. He said Clarence Darrow was their attorney and would take care of the case. Dr. Weiser and Dr. Adson are here to talk to you about the attitude of the Board. I feel safe in saying that the Medical Board intends to prosecute these fellows, and we have received wonderful coöperation from the Medical Association of this state. We had a fellow prosecuted in New Ulm last week for doing what we call bleeding and cupping. He charged one person $70.00 for it. He was fined $500.00.

A large number of people write to Dr. Meyerding, and we try to get right behind them and go after them. The medical profession is interested in this problem, and yet the Board cannot do much if the Legislature amends the laws so as to take the teeth out of them.

I want to assure you on behalf of the Medical Board that as long as we have your support we will prosecute the quacks of this state.

PRESIDENT BOYER: We will now hear from Dr. Weiser.

DR. WEISER (New Ulm): I think we are very fortunate in having such an aggressive supporter as Mr. Brist, and in the majority of instances we have been very successful. Mr. Brist does not prosecute these illegal practitioners without first making a very thorough investigation, so all the prosecutions have been successful.

DR. ADSON (Rochester): The Board of Examiners coöperates with us in every manner and they have been making an attempt to keep the expenses down, reasonable with the effort accomplished.

DR. MANLEY: I move the adoption of the report of Dr. Johnson.

Motion was seconded and the report adopted.

PRESIDENT BOYER: The Reference Committee.

DR. MANLEY: The report of the Committee on Medico-Legal Affairs.

REPORT OF COMMITTEE ON MEDICO-LEGAL AFFAIRS

The Committee on Medico-Legal affairs has held no definite meeting except that its members were present at the general Committee meeting held by Dr. Boyer, in Minneapolis, February 10, 1930.

It has been the belief of the Committee on Medico-Legal affairs that the time is ripe in the State of Minnesota for some constructive legislation along the lines of expert testimony, particularly with reference to the mental status of criminals being brought to trial. It has been felt desirable to have the initiation of such legislation as in the State of Massachusetts, whereby the matter of sanity of criminals is not brought before a Jury for decison, but is determined by a Commission or Board appointed for that purpose, and that the matter of the sanity of the criminal should never be left

to a lay jury to determine. In view of the fact that this involves an amendment to the Constitution of the State of Minnesota, it is impossible to make any rapid progress in the enactment of such legislation. It is felt by this Committee that such legislation should primarily be enacted through the legal profession, with the moral support of the medical profession of the State. No definite work has been done in regard to this except informal inquiries of members of the Bar Association. We cannot report progress in this matter, but merely outline what we believe to be a policy for constructive legislation in this State.

There was referred to this Committee a communication from Margaret Sanger, of New York City, requesting endorsement of a bill to be introduced in Congress to amend the penal laws concerning birth control. It is the recommendation of this Committee, by a vote of four to one, that the House of Delegates do not endorse 'this bill.

There has been in the hands of this Committee, also, for consideration, another matter relative to one member of the State Medical Association, which matter is still in the process of investigation and upon which, at this time, the Committee is not ready to make a report.

Other than this, this Committee has no activity to report.

W. H. Hengstler, M.D., *Chairman.*

PROPOSED AMENDMENTS TO SECTIONS 334 AND 396 OF TITLE 18 OF THE UNITED STATES CODE AND SECTION 135 OF TITLE 19 OF THE UNITED STATES CODE

Section 211 Penal Laws is Section 334 United States Code.

Section 245 Penal Laws is Section 396 United States Code.

Sections 311 and 312 Penal Laws are Sections 511 and 512 U. S. Code.

Section 305a Tariff Act 1922 is Section 135 of Title 19 U. S. Code.

The Provisions of this Section shall not apply

(1) to information relating to the prevention of conception published either within or without the United States by a governmental agency, medical society, medical school, medical college or medical journal, or reprinted by any individual or organization after such publication, or

(2) to information relating to the prevention of conception sent by a licensed physician, hospital or clinic to another licensed physician, hospital or clinic or to a patient, or

(3) to information regarding the names and addresses of licensed physicians, hospitals and clinics in the State of destination which give advice relating to prevention of conception, or

(4) to any article, substance, drug, medicine or thing for the prevention of conception sent from within or without the United States to a bona fide wholesale or retail dealer in medical supplies or a licensed physician, hospital or clinic, or sent by a licensed physician to a patient.

Dr. Manley: The Reference Committee recommends the adoption of this report and concurs in the recommendation of this committee that the House of Delegates do not endorse the bill sponsored by Margaret Sanger of New York City, amending the penal laws concerning birth control.

Dr. Hammes (St. Paul): The Medico-Legal Committee felt that some ways or means should be devised by which attention would be brought to the Legislature through the Bar Association in changing the laws in some way that this can be done. At the last meeting of the American Medical Association this same matter came up before the Committee on Nervous and Mental Diseases. A resolution which covered this matter was adopted, the resolution being as follows:

"RESOLVED, That the Section on Nervous and Mental Diseases hereby declares its adherence to the principles stated in the Report of the Committee on Psychiatric Jurisprudence, Section on Criminal Law and Criminology, American Bar Association, and approved by that association at its meeting held in Memphis, Tenn., Oct. 24, 1929, namely:

"1. That there be available to every criminal and juvenile court a psychiatric service to assist the court in the disposition of offenders.

"2. That no criminal be sentenced for any felony in any case in which the judge has any discretion as to the sentence until there be filed as a part of the record a psychiatric report.

"3. That there be a psychiatric service available to every penal and correctional institution.

"4. That there be a psychiatric report on every prisoner convicted of a felony before he is released.

"5. That there be established in each state a complete system of administrative transfer and parole, and that there be no decision for or against any parole or any transfer from one institution to another, without a psychiatric report.

"RESOLVED, Further, that the section recommends that the House of Delegates of the American Medical Association adopt the principles stated above and request the Board of Trustees to take such action as may be necessary to bring about the coöperation of state and county medical associations with corresponding state and local bar associations in securing, as far as possible, the adoption of these principles in practice."

I think the fourth and fifth are the most important. I want briefly to cite two cases to show the kinds of such cases. Some years ago a discharged soldier conceived the idea that I was attempting to prevent him from obtaining his compensation. His attitude was quite threatening but quite normal. One day he dropped into Red Cross headquarters and told them he was trying to get me but that I was protected by the Democratic Government and he couldn't get at me, but he could get my wife and children. He described my home; and I took it up with the Probate Court and he was, after four hours of examination, found to have delusions. If the police had handled this case he probably would have got thirty or sixty days in jail and been released.

The second case was one we had last week before Probate Court. It was this man's third robbery, and here he was simply an accomplice. He waited about

a block away from his uncle's home while the other man robbed it, and the only reason he could assign was that this man was a friend of his. This man's intelligence quotient was 61. We recommended to the court that he be sent to Faribault. If this examination had not been made he would have received thirty or sixty days or a year and been out again.

The report was adopted by a vote.

The Reference Committee will proceed.

DR. MANLEY: Report of the Committee on Schools for Laboratory Technicians, Dr. A. G. Schulze, Chairman.

REPORT OF THE COMMITTEE ON SCHOOLS FOR LABORATORY TECHNICIANS

This Committee began its investigation by sending a postal card questionnaire to each of the 44 class "A" hospitals in the State of Minnesota as well as to the various medical clinics in the State.

From the answers received we learned that training of medical technicians is being carried on in thirteen of these hospitals and clinics, which number, added to the three commercial institutions which are in existence, makes a total of sixteen places, practically all located in the Twin Cities, where the training of medical technicians is being carried on.

A second questionnaire was mailed to these sixteen institutions and a reply was received from twelve of them. An analysis of these twelve replies forms the basis of our report.

The following replied:

St. Mary's Hospital, Duluth
Minneapolis General Hospital, Minneapolis
Northwestern Hospital, Minneapolis
Swedish Hospital, Minneapolis
University Hospital, Minneapolis
Ancker Hospital, St. Paul
Charles T. Miller Hospital, St. Paul
St. Joseph's Hospital, St. Paul
St. Luke's Hospital, St. Paul
St. Paul Clinic, St. Paul
N. W. Institute of Medical Technology, Minneapolis
Physicians' Clinical Laboratory, St. Paul

The following did not reply—

Asbury Hospital, Minneapolis (does not teach technology)
St. John's Hospital, St. Paul (report received late)
Professional Service Bureau, Minneapolis (did not report)
Mayo Clinic, Rochester (does not teach technology)

Degree of Director.—In all of these institutions, with the exception of a single clinic, the director holds the degree of "Doctor of Medicine," while in the single exception stated the degree of "B.S." is held.

Length of Course.—Three of the institutions give a six months course (this is the shortest); one school offers an eight months course; two schools offer a nine months course; five schools offer a twelve months course, while the course at the University Medical School covers four years.

Entrance Requirements.—The minimum entrance requirements in nine of the schools is a high school education; in two it is high school education or degree of registered nurse; while one school requires a college graduation.

Certificates Awarded.—There is only one school that does not award a diploma or certificate of some kind at the end of the course.

Source of Teaching Material.—One of these schools being connected with a clinic it is very obvious that the teaching material and specimens for teaching purposes are obtained through the work of the members of that clinic. Nine of the schools are connected directly and physically with hospitals and the pathological specimens and resources of those hospitals are used for teaching material for the student technicians. Two of the institutions are purely commercial and are not connected directly with any hospital but claim to be supplied with teaching material from various sources. For instance, the N. W. Institute of Medical Technology claims to receive material from the U. S. Veterans' Hospital, the State Board of Health and various practicing physicians. Another institution claims to receive material from hospitals, physicians and the St. Paul Board of Health.

Further investigation reveals the fact that the U. S. Veterans' Hospital is supplying some specimens to the N. W. Institute of Medical Technology and the State Board of Health has also supplied some cultures in the past and the St. Paul City Laboratory has also coöperated to some extent with the second institution but both of these laboratories are questioning the wisdom of this association, and will no doubt discontinue it.

We doubt whether any hospitals are supplying any material to these institutions for teaching purposes.

Students, Fees and Advertising.—These twelve institutions can very readily be divided into three groups. In the first group we have the University Medical School only. It has a class of 80 students, charges $40 per quarter and the course is four years long. There is no advertising program carried on beyond that which is carried on by the General University.

In the second group of schools we have those connected with the various hospitals. The number of pupils in their classes runs from one or two, to two, four, six and eight; rather small classes. Five of these schools charge no fees at all; three charge $50 and give the books, some meals and laundry. Another school charges a fee of $100 but makes no mention of books, meals, etc. None of these schools carry on any advertising.

In the third group are the so-called commercial institutions. One of the schools included in this report has a class of fifteen students, charges $215 for a six months course and carries on an advertising program by means of letters and advertisements in the local papers. The other commercial school charges $250 for a six months course, claims to have accommodations for 104 students and carries on a remarkable advertising program by means of catalogues and follow-up letters.

Method of Teaching.—The most important part of this survey and report pertains to the actual method of instruction which is employed, but on this point it is difficult to get full detailed information.

There can be no doubt that the four year course at the University Medical School under the directorship of Dr. Wm. A. O'Brien and his corps of technician supervisors, all of whom have a degree of "B.S." or "M.S.," is a good course and that the instruction is thorough. The greatest objection to this course, as voiced by prospective students, is the long four year period.

The courses given in the various hospitals where the laboratory material is practically without limit, where the classes are small, where the instruction is carried on by personal contact and supervision on the part of whole time trained technicians, are excellent courses and quite beyond criticism. But, the classes are so small, the waiting list is so long, that the prospective student becomes discouraged and looks elsewhere.

The commercial institutions, therefore, with their advertising program and promises of excellent positions, become attractive. How plentiful is their teaching material when they are not intimately or actually connected with a hospital? How thorough is the instruction in a short six months course when the actual teaching staff of whole time trained instructors is obviously too small for the number of students enrolled? A long, imposing list of subjects taught and apparently many didactic and laboratory hours devoted to them may mean nothing when the method of instruction is considered. There is a vast difference between lectures by part time men and the constant personal and direct instruction and supervision of full time trained technicians.

It is to be regretted that here in the State of Minnesota we have no laws governing or controlling the activities of Schools of Medical Technology or other similar schools; so there is practically no limit as to what may be done and still remain within the law. The creation of such laws may well be considered by our Committee on Legislation.

However, the Registry of Technicians of the American Society of Clinical Pathologists requires the following minimum preparation and qualifications:

(a) Graduation from an accredited high school.
(b) One year of didactic work in basic sciences, including chemistry, bacteriology, physiology and pathology, together with laboratory demonstrastratic or its equivalent.
(c) Six months of actual experience in a recognized clinical research or public health laboratory.

It certainly is not unreasonable to expect all institutions teaching medical technology to have a standard of minimum requirements for graduation which will enable its graduates to register with the American Society of Clinical Pathologists.

Certainly no institution teaching medical technology can expect to have the endorsement of organized medicine that does not have at its head a director who has the title of "M.D." or whose teachers are not registered technicians; that has not sufficient physical equipment to properly carry on this work and is not actually connected with a hospital; whose course is not at least twelve months, or that is openly commercial or carries on pernicious advertising.

What should be the attitude of the various component societies of the Minnesota State Medical Association towards those of its members who lend their name and their title as instructors which do not meet with the above requirements? One county society demanded of its member that he either give up his teaching position or resign his membership.

Another School of Medical Technology, which might be classed as a commercial concern, returned its questionnaire too late to be included in the above listing, but the answers submitted are as follows:

The Director of the School has the title of "M.D." but he evidently does none of the instructing. They offer a six months course, call for high school requirements and issue a certificate when the work is completed.

Their teaching material comes from the hospital in which the school is located and from the U. S. V. Hospital. They have a class of 24 students and charge $40 per month but it is plain that all the teaching is done by one technician.

They also offer a two months course in X-ray technic, physiotherapy and basal metabolism for $125, accommodating 15 students, but here again all this teaching is done by a single instructor who has prepared himself along these lines.

This school is contemplating substantial improvement by the middle of July.

Dr. Manley: This is a very excellent report and the committee has investigated most of the technology schools in Minnesota. There are many things in this report that demand careful consideration.

The Reference Committee recommends that the report be referred to the Council, with particular reference, first, to any new legislation, and, second, to discipline the members of the Society who lend their names to sub-standard schools, and, third, the appointment of a local member of the National Registry of Technicians to the State Committee.

We recommend the acceptance of this report, and feel that the committee should be continued.

Dr. Schulze (St. Paul): I regret very much that the questionnaires the committee sent out were not received in time so this report could go to the hands of the delegates. There are one or two important parts of this report. One of these schools being connected with a clinic, it is very obvious that the teaching material and specimens for teaching purposes are obtained through the work of the members of that clinic. Nine of the schools are connected directly and physically with hospitals and the pathological specimens and resources of those hospitals are used for teaching material for the student technicians. Two of the institutions are purely commercial and are not connected directly with any hospital but claim to be supplied with teaching material from various sources. For instance, the Northwest Institute of Medical Technology claims to receive material from the United States Veterans' Hospital, the

State Board of Health and various practicing physicians. Another institution claims to receive material from hospitals, physicians and the St. Paul Board of Health.

Upon a vote the report was adopted.

Dr. Manley: I move that this matter be referred to the Council for further study.

This motion was seconded and carried.

President Boyer: The Reference Committee.

Dr. Manley: Report of the Committee on Public Health Nursing, Dr. C. B. Wright, Chairman.

REPORT OF THE COMMITTEE ON PUBLIC HEALTH NURSING

This Committee has had six meetings, November 29, December 5, December 18, December 30, 1929, and January 23, and June 4, 1930.

At these meetings were the Chairman, one or two other members of the Committee, also the Director of the Public Health Nurses, University of Minnesota; Director of Visiting Nurses of Minneapolis, Superintendent of Public Health Nursing, State Department of Health; a physician active in public health work, a rural nurse and lay member of a rural nursing committee. These meetings grew out of a conversation which your Chairman had with Miss Fox, representing the National Public Health Nursing organization, and later with Miss Olivia Peterson of the Division of Child Hygiene, University of Minnesota.

There are in Minnesota public nurses employed by, and responsible to, various agencies such as Child and Maternal Hygiene Nurses, School Nurses, Tuberculosis Nurses, Red Cross Nurses and County Nurses, who are employed by local school boards, Red Cross, county commissioners, State Board of Health, and these nurses are working, in many instances, with entirely inadequate supervision. It was felt that some mechanism should be instituted for better medical supervision of their work and to have certain rules and regulations drawn up that nurses may follow in emergencies until proper medical assistance can be secured.

Consequently, a set of emergency rules and regulations were drawn up and have the indorsement of this Committee. A copy of these rules will be sent to every member of the House of Delegates for their consideration and correction, and, if satisfactory, for their approval. It was also recommended that a medical advisory group be organized, consisting of members of the State Medical Association outside of the three larger cities, to advise with the state nursing organizations and it is also recommended that a similar committee be appointed from each county society, outside of the three larger cities, to act as a Medical Advisory Board to nurses working in their respective districts.

Respectfully submitted by the Committee on Public Health Nursing,

Dr. W. H. Condit
Dr. J. T. Christison
Dr. George Earl
Dr. C. B. Wright, *Chairman*

SUGGESTED POLICIES AND STANDING ORDERS FOR PUBLIC HEALTH NURSES

We have in Minnesota many nurses doing various types of public health work, some of whom are working with mothers and babies; others in schools; some in communities whose chief interest is in the control of some particular disease, such as tuberculosis; still others have developed programs to fit some particular health need.

These nurses are employed by various agencies, such as local school boards, county commissioners, Red Cross chapters, etc. The machinery for medical supervision is available in the Nursing Advisory Committee, as the law specifies that a doctor should be a member of this committee. In many instances, however, this has not provided satisfactory medical supervision for public health nursing services. Nurses also make monthly reports to the Superintendent of Public Health Nursing in the State Department of Health, and may receive upon request advisory service from the same source.

A committee from the State Medical Association, appointed by the President of the Councillors, is working with a committee, appointed by the State Organization for Public Health Nursing, comprised of the Director of the Public Health Nursing Course, University of Minnesota; the Director, Minneapolis Visiting Nurse Association; the Superintendent of Public Health Nursing, State Department of Health; a physician active in public health work; a rural nurse; and a lay member of a rural nursing committee. This committee feels an effort should be made to have more medical supervision of health programs as carried on in these local communities, and to have certain rules and regulations drawn up which the nurses may follow in the various types of work in which they are engaged.

After several meetings of this committee, some suggestive general rules and standing orders have been drawn up governing public health nursing. These are presented for your consideration.

1. Any agency employing public health nurses shall have its program approved by the local organized medical group.

2. Nursing care should be continued, after the first visit, only under the direction of a licensed physician.

3. The nurse shall not recommend the selection of any individual physician. Free medical care found necessary after careful consideration of economic condition of patient may be provided for either through a volunteer service of local physicians or through the use of facilities provided by the state and municipality with the approval of the family physician.

4. The nurse does not diagnose nor prescribe treatment. It is, however, her function to carry out the doctor's instructions. The local medical group should approve minimum routine standing orders (see list attached). Records of such nursing care should be kept on file by the nurse.

5. The establishment of clinics or other events which involve medical service should be undertaken only after consultation with the medical societies or local physicians.

6. Every public health nurse should understand and support regulations of the local and state health departments and shall keep in direct contact with their personnel.

7. Every nurse engaged in public health nursing should be eligible for certification in Minnesota as provided by law. See Sec. 4, Chapter 196—S.F. 495.

8. The work of every nursing agency should be carefully and consistently recorded and the nurse should give a report periodically to the person or group responsible for the service and to the State Department of Health as provided by law. See Sec. 5, Chapter 196—S.F. 495. (It is recommended that these reports be given publicity.)

STANDING ORDERS

Standing orders are those orders for treatment and medication which can be used until a physician can be secured or when orders have not been left by the attending physician. The following are examples of standing orders frequently used:

New Patients.—General or partial care as the situation indicates. Instruct family in hygiene of the sick room and care of the patient until next visit. Explain continuance of nursing care depends upon attendance of physician.

Elevated Temperature.—Put patient to bed. Urge importance of quiet and rest. General isolation routine if communicable disease is suspected. Liquid diet. Plenty of water. Sponge for temperature of 102 to 105. If patient is suffering from abdominal pain, family should be instructed to give nothing by mouth, until patient has been seen by the physician.

For Infants and Children with Fever, Undiagnosed.—Normal salt flushing when required. Diet: Boiled water for twenty-four hours.

Sore Throats and Colds.—Isolation. Plenty of water. Liquid diet. Urge medical attention.

For Discharging Ears.—Cleanse the outer ear with moist boric solution swabs. Dry thoroughly. Do not irrigate. Emphasize need of prompt medical attention.

Ulcers (Chronic).—Cleanse with normal salt or boric solution. Apply hot dressings of either solution and a firm bandage.

For Dressing, Minor.—Cuts, bruises, infected fingers, scratches. Apply mercurochrome, alcohol or tincture of iodine followed by alcohol direct to wound or abrasion. Cover with gauze or clean handkerchief. Advise medical observation in every case.

Emergencies and Accidents.—Communicate with physician. First aid treatment until medical aid is secured. If patient is a minor, communicate with parent immediately if possible.

Burns.—Always consider burns as serious injuries. Remove clothing, if possible, and if area of burn is extensive, remove patient to hospital as soon as possible. For first aid, if there is severe pain, apply vaseline, sweet oil, normal salt solution, or boric acid solution and advise calling physician.

Prenatal Cases.—Aim to bring patient under the care of her physician at once. Acquaint patient with the educational literature obtainable from the State Department of Health. Take temperature, pulse, respiration. If possible, bring a specimen of urine in to her physician unless this has been done recently or will be done soon by the patient. If the patient is to have a home delivery, help make up the necessary sterile supplies as advised by the Division of Child Hygiene in literature distributed by them. Call as often as needed to help the patient with her diet or any treatment ordered by the attending physician.

Obstetrical Cases.—For the mother, cleansing bath. Change pads. Perineal irrigation with ½% of lysol solution. Leave in warm, dry bed. For baby, oil and bathe. Sterile cord dressing. Keep warm. Every nurse is charged with the responsibility of being concerned with the protection of the eyes and the registration of the birth as provided for in the state law.

Post-Partum Hemorrhage.—Send someone else for physician immediately. Elevate foot of bed. Put patient in elevated Sims position. Keep patient quiet and warm. *No hot drinks.*

Puerperal Mother.—Cleansing bath. Local cleansing with antiseptic solution. Sterile dressing to breasts and vulva. Urge patient to go to physician for post-partum examination.

Nurses engaged in school nursing will often see abnormal skin conditions, inflamed eyes and symptoms which suggest the onset of communicable disease. Where it is difficult to get a doctor to assume responsibility, it is recommended that instructions be included in the standing orders indicating what the nurse is to do in these matters.

It is recommended that instructions endorsed by the Medical Association listing the symptoms which call for the exclusion of children from school and setting forth the procedure to be followed by the nurse in notifying the family, the family physician, etc. Such instructions, of course, must agree with the local and state laws and ordinances.

DR. MANLEY: This committee has drawn up rules governing the conduct of the various classes of public health nurses, and the Reference Committee believes that the House of Delegates should lend its support to these rules and to the work in general. We recommend that these rules be taken up before local societies and modified to meet local conditions.

We recommend the acceptance of this report.

Upon motion and vote the above report was accepted.

DR. MANLEY: Report of the Committee on Contract Practice, Dr. Webb, Chairman.

REPORT OF THE COMMITTEE ON CONTRACT PRACTICE

The Committee on Contract Practice held one meeting this year at the time of the general meeting held at the Leamington Hotel.

In last year's report it was stated that the Committee felt that the situation as to Contract Practice was satisfactory to all concerned and it was the sense of the Committee that it should confine its activities to consideration of complaints on Contract Practice as brought to its attention during the year.

As nothing further has been brought to the atten-

tion of this Committee, we have nothing further to report at this meeting.

It has been suggested that the name of the Committee be changed to Committee on Traumatic Surgery and Contract Practice.

R. C. Webb, M.D., *Chairman.*

Dr. Manley: Since there are no reasons for a change in name given in the report, the Reference Committee recommends the retention of the old name "Committee on Contract Practice," and asks for a full discussion of this matter by the House of Delegates, with two particularly important points in mind. First, the matter of efficient service to the patient, and, second, the matter of the development of an adequate and more or less uniform rate of compensation for the physician, bearing in mind the fact that some localities might advantageously have a different rate of compensation from another.

The Reference Committee recommends acceptance of this report, and feels that while a complete solution of this problem is very difficult, an attempt should be made to solve some of the more urgent problems.

Upon motion and vote the report was accepted.

President Boyer: The Reference Committee desires a discussion on the two points involved, the quality of service rendered and the compensation received. Dr. Collins, can you tell us about this?

Dr. Collins (Duluth): Our committee has only had one meeting, as far as I know, and I wasn't present at that meeting. However, there is a very brief report that has been handed in which represents all the deliberations I am familiar with. There is very little we can do with regard to contract practice. There has been some discussion as to whether we should change our name to Committee on Traumatic Surgery.

Dr. Manley: The report of the Committee on University Relations, Dr. S. H. Boyer, Chairman.

REPORT OF UNIVERSITY RELATIONS COMMITTEE

There has been no meeting of this committee thus far this year. There has been but one matter brought to the attention of the committee up to date. This is in relation to the distribution of radon seeds to the medical profession by the University of Minnesota.

It appears that a considerable number of doctors have desired to avail themselves of the use of radium emanations and, laboring under the impression that they could obtain emanations from the University, have learned upon request that they were mistaken. After discussing this subject by mail with members of the University Relations Committee, it was decided to ask Dean Lyon for an explanation. The dean replied, after he had made an investigation, that the amount of radon seeds available is not sufficient to permit of a uniform supply to the doctors of the State and that, therefore, no arrangements had been made with them. He explains further that occasionally a little is left over, but not regularly. The shortage of seeds upon the part of the University is due to the possession of a comparatively small amount of radium. It is hoped that the University will be able to find ways and means whereby it can increase its supply.

It is interesting to note that the only place in the United States from which radon seed may be obtained is the Standard Radium Corporation of America with offices in New York City. At one time this corporation maintained a branch office in Chicago, since closed. The Standard Radium Corporation of America represents the merging of all other concerns in this country which were in the radium business.

Very truly yours,

S. H. Boyer, M.D., *Chairman.*

President Boyer: When the radium plant was established at the University of Minnesota the feeling on the part of the profession was that the Minnesota profession would be able to receive radium emanations from that source. It was later given out by the head of the department that there were no radium emanations to spare, and because of this fact no arrangements had been made with the doctors of the state to supply them. He stated further that occasionally a little is left over, but not regularly, and that the shortage of seeds on their part is due to the possession of a comparatively small amount of radium. We hope the University will be able to find a way to increase its supply.

At the present time the Standard Radium Corporation of America with offices in New York controls the entire situation, and if you want any of these seeds you must obtain them from this company. I don't know what further can be done about it.

Upon a vote a motion to accept the report was carried.

Dr. Manley: Report of the Committee on Military Affairs.

REPORT OF THE COMMITTEE ON MILITARY AFFAIRS

Resolution to be presented to the House of Delegates of the Minnesota State Medical Association by the Committee on Military Affairs:

WHEREAS, The present Army regulations require that every reserve officer shall, during each five years commission period, put in two hundred (200) hours military work, in camp, correspondence school, in active training meetings, or similar military activity, or else become ineligible for renewal of his commission with assignment to an Organized Reserve Unit, and therefore revert to the "Auxiliary Reserve" in time of peace, and

WHEREAS, There are many highly trained, highly skilled and very active physicians who, as reserve officers, have been assigned as chiefs and assistant chiefs of surgical, medical, laboratory, roentgen and other distinctly professional services in Organized Reserve Hospital Units, carrying very little administrative responsibility, and whose professional duties in busy private lives make them especially well fitted for their duties in their army assignments, but whose same duties make it practically impossible for them to carry on military work in time of peace, and

WHEREAS, Many of these men and their valuable attainments are being lost to the Organized Reserve,

although they are willing and anxious to serve in time of need and do not aspire to advancement in grade,

THEREFORE, be it resolved, that the Minnesota State Medical Association, desiring that the Medical Profession may be of the greatest service to our country, respectfully suggests that the service might be enhanced if the regulations were changed to provide for recommission and reassignment of chiefs and assistant chiefs of professional services of Hospital Units even though they have not completed the required amount of military work, and further,

Be it resolved, That a copy of this resolution be sent to the Surgeon and the Commanding General of the Seventh Corps Area, The Surgeon General, the Officer in charge of Reserve Affairs, the Adjutant General and The Chief of Staff of the United States Army.

RALPH T. KNIGHT, M.D., *Chairman.*

DR. MANLEY: The Reference Committee recommends the adoption of this report.

The report is voted upon and approved.

PRESIDENT BOYER: There are some communications to be acted upon at this time.

DR. MANLEY: This is a communication from the Inter-State Post-Graduate Medical Association of North America, officially inviting this Society to attend their meeting in Minneapolis October 20th to 24th. I move that the Secretary acknowledge the invitation with thanks.

This motion was carried.

DR. MANLEY: This is a communication from the Minnesota Department of Health relative to their work in connection with maternal mortality.

MINNESOTA DEPARTMENT OF HEALTH

To the House of Delegates,
Minnesota State Medical Association:

As reported in the letter of June 30 to your Secretary and to your President, the study of the maternal mortality conditions in Minnesota undertaken by the Division of Child Hygiene of the State Department of Health in coöperation with the Federal Children's Bureau is sponsored by this body. The results of the investigations carried on in Minnesota are now in the hands of the statisticians of the Children's Bureau. Owing to the press of work of statistical material demanded by the White House Conference they have been delayed in completing this maternal mortality study. It will, however, be available sometime within the next few months. In the meantime, this very brief statement regarding the Minnesota maternal deaths may be made:

MATERNAL DEATH RATES

Year	*Minneapolis*	*St. Paul*	*Duluth*	*State*
1928.....	5.63	6.61	8.22	5.25
1929.....	4.40	4.46	4.16	4.27

In addition we wish to mention at this time the extremely coöperative and helpful manner in which the physicians throughout the state received the representative of the Board who carried on this study. The doctors' records were always placed at his disposal and such additional information as either the doctor or the hospital could furnish was always made available to our representative. We feel that this helpful and coöperative spirit in connection with this study is perhaps a conspicuous factor in explaining why Minnesota stands so high in the matter of its maternal and also of its infant mortality rates.

DR. MANLEY: The Reference Committee commends the work being done by the Minnesota Health Department and believes that during the course of years statistics will be available which will be of great practical value.

I move the acceptance of the communication.

Motion was seconded and carried.

DR. MANLEY: This is a new resolution, of which the delegates have not had a copy, presented by the Hennepin County Medical Society. The following resolution was adopted at a meeting of the Executive Committee of the Hennepin County Medical Society on February 28, 1930, and was passed by the Society. The Executive Committee recommends that the delegates of the Hennepin County Medical Society be instructed to present the following resolution:

"That a committee of five be appointed by the President to make a careful study of the policies of the State Medical Association, particularly along the lines of the consideration of the problems and development of the County Societies, of redistricting of the Association, accumulation of reserve fund, the organization of permanent committees and changes in the personnel or the duties of the executive officers, and to make such recommendations as they deem advisable for the best interests of the Association and the component Societies."

The recommendations to be presented at the House of Delegates at the 1931 meeting.

The Reference Committee has approved this resolution, and I move its adoption.

DR. SAVAGE (St. Paul): It seems to me that this matter should first go before the Council rather than be referred to the House of Delegates. The Council is probably more familiar than any similar number of men with the various problems which confront the State Medical Association, and of course the function of this committee is the job of the Council. I don't think there is any objection at all to a study being made of the activities of the State Association, but I do feel that this report should be submitted to the Council for their opinion.

PRESIDENT BOYER: Will you submit that as an amendment to the original motion?

DR. SAVAGE: I offer that as an amendment.

DR. MANLEY: I accept it.

The motion was then voted upon and carried.

PRESIDENT BOYER: Applications have been received from the following for associate membership in the Association: Thomas G. Lee, Minneapolis; John F. Noble, St. Paul; Donald Smelzer, Philadelphia.

Motion was made, seconded and carried that the above mentioned applications be approved.

DR. MANLEY: This is a resolution presented by the Hennepin County Medical Society having to do with the recognition of Dr. Farr's work. This resolution

was presented before the Minneapolis Surgical Society on March 6, 1930. It is as follows:

"The recent enthusiasm over various forms of anesthesia other than those in use fifteen or twenty years ago make it evident that anesthesia of that time was not all that could be desired. Recent information has taught us beyond doubt that our surgical mortality has been reduced by the introduction of some of the newer types of anesthesia.

"By his untiring efforts, patience and persistence, Dr. Robert Emmett Farr, a member of this organization, has perhaps done more than any other man to bring about the widespread dissatisfaction with the general use of the old form of anesthesia.

"By his skillful administration of local anesthesia and his extensive writings and demonstrations thereon, he has convinced the medical profession that at least in certain types of surgery lives can be saved by substituting this method for those generally accepted by surgeons of the past.

"Therefore, be it resolved, that because of his contribution to surgery, his service to mankind, his part in the preserving of human lives, Robert Emmett Farr, one of our esteemed members, be recommended by the Minnesota State Medical Association to the committee as a recipient of the next annual Nobel Prize."

The Reference Committee recommends the adoption of this resolution.

The resolution was voted upon and adopted.

DR. MEYERDING: The following is a petition received from resident physicians of Dakota County:

"We, the undersigned physicians, residents of Dakota County, hereby petition the House of Delegates to grant a charter to the Dakota County Medical Society.

G. F. WALTER, Farmington,
T. J. GAFFNEY, Lakeville,
J. A. SANFORD, Farmington,
W. T. HAGERTY, Cannon Falls,
L. D. PECK, Hastings,
H. A. FASBENDER, Hastings,
L. R. PECK, Hastings."

DR. SAVAGE: I move that the House of Delegates recommend the granting of a charter to the Dakota County Medical Society.

This motion was seconded and carried.

DR. MEYERDING: Here is a petition presented by the Camp Release District Medical Society:

"Will the House of Delegates request the different committees to have their reports in at a definite time and mailed to the different societies; the idea being to get action from the component organizations in time to take it to the annual meetings?"

The Secretary endorses this communication from the Camp Release District Medical Society. The Secretary's office mails this material as soon as possible to those authorized to see it, as they can testify. It was necessary to send three different sets of material to the delegates when one should have been sufficient.

This recommendation was approved.

PRESIDENT BOYER: Is there any new business to come before this meeting?

DR. MEYERDING: I would like to announce that the Council will meet here twenty minutes after adjournment of this meeting.

PRESIDENT BOYER: We will meet here tomorrow at 2:00 P. M.

Motion was made, seconded and carried that the meeting adjourn.

The meeting adjourned at five-fifteen o'clock.

SECOND MEETING OF THE HOUSE OF DELEGATES

The second meeting of the House of Delegates, held in the English Room of the Duluth Hotel, Duluth Minnesota, in conjunction with the Sixty-second Annual Session of the Minnesota State Medical Association, July 14-16, 1930, convened at two-ten o'clock, July 15, Dr. S. H. Boyer, President, presiding.

PRESIDENT BOYER: Gentlemen, come to order, please. We will have the roll call.

Secretary Meyerding called the roll.

PRESIDENT BOYER: All those whose names have not been called, stand.

PRESIDENT BOYER: Supplementary report of the Credentials Committee.

SECRETARY MEYERDING: Are you ready, Dr. Boleyn, with your Credentials Committee report?

DR. E. S. BOLEYN: Fifty-six.

PRESIDENT BOYER: Summary of the minutes of the preceding meeting.

Secretary Meyerding read the minutes.

PRESIDENT BOYER: You have heard the report, gentlemen. Are there any corrections?

DR. ALBERT G. SCHULZE (St. Paul): On the report of Dr. Manley's Reference Committee on the report of the Historical Committee no mention was made of changing the date of the organization, 1853.

SECRETARY MEYERDING: That is just a synopsis. That will be in the regular minutes. The reporter made a very brief synopsis.

DR. S. H. BAXTER (Minneapolis): This may be in the nature of new business, but it relates to one of these reports. That is the report of the Committee on Military Affairs in which the Committee made certain recommendations or suggestions to the surgeon-general, and it has been suggested to me that it might be of some weight if this resolution or something similar to it would be presented and passed by other state medical associations. Therefore, I would like to move that the Secretary communicate this report and recommendations to other societies with the idea that the combined influence might have some effect in having these suggestions put into effect.

The motion was seconded and carried.

PRESIDENT BOYER: Are there any further corrections or remarks? What will you do with the minutes?

DR. F. J. SAVAGE (St. Paul): I move their adoption.

DR. ALBERT G. SCHULZE (St. Paul): I second it.

PRESIDENT BOYER: If there is no objection the report will stand as read.

Next is the report of the Council.

Dr. H. M. Workman, Tracy, read the report of the Council.

SECOND MEETING OF THE COUNCIL

The second meeting of the Council was held on Monday, July 14, 1930, at the Hotel Duluth. The meet-

ing convened immediately after the House of Delegates' meeting.

The following were present: H. M. Workman, W. H. Condit, G. S. Wattam, F. J. Savage, F. A. Dodge, W. A. Coventry, L. Sogge, W. W. Will, M. S. Henderson, E. A. Meyerding.

Motion made by Dr. Sogge seconded and carried that the minutes of the last meeting be approved as written.

Motion made by Dr. Savage, seconded and carried that the Committee on Schools for Laboratory Technicians be continued and that it endeavor to establish a standard whereby schools may be classified.

It was suggested that the President of the Council read to the House of Delegates letters from the Parents-Teachers Association and the opinion of the Attorney General regarding pre-school examinations.

It was recommended that the chairman of the Board of Medical Examiners be made a member of the Committee on Hospitals and Medical Education.

The meeting adjourned.

Secretary Meyerding: You will recall the Council appointed the President of the Committee to confer with the President of the Parents-Teachers Association relative to the summer round-up, and this is the President's letter of March 12 to Mrs. A. H. Mendenhall, President Minnesota Congress of Parents and Teachers, and her reply.

March 12, 1930.

Mrs. A. A. Mendenhall, President,
Minnesota State Parent-Teachers Association,
1528 Jefferson Street,
Duluth, Minnesota.

In re: Summer Round-up of Children of Pre-school Age.

Dear Mrs. Mendenhall:

Answering the request of the Parent-Teachers Association for endorsement of the above mentioned movement by the Minnesota State Medical Society:

First: The Minnesota State Medical Society is in sympathy with anything tending to promote either public or private health or both.

Second: We are not in favor of health examinations *en masse*, inasmuch as we believe this method to be wasteful of time, inefficient in process and therefore faulty in its final diagnostic conclusions and advice as to treatment.

Third: We believe that physicians lending their aid to this activity should render thoroughly good service and receive commensurate compensation for their work.

Fourth: It is our belief that, in the prosecution of this work, the parents and guardians of children about to enter school should be encouraged to have their children examined by physicians of their own choice (preferably their family physician) and at their own expense. The children of those who for any reason are unable to meet their financial obligations should be examined by one or another of the free agencies.

Fifth: We recognize that in some few localities, owing entirely to local conditions, the examination must be conducted at public expense.

Taking the above provisions into consideration and believing that your association will not be unmindful of them in carrying on your work, the Minnesota State Medical Association whole-heartedly endorses the movement and assures you of its genuine coöperation.

Very respectfully yours,
S. H. Boyer, M.D., *President.*

Minnesota Congress of Parents and Teachers
State Headquarters
200 City Hall, Duluth, Minnesota
March 12, 1930

Dr. S. H. Boyer, President,
State Medical Association,
Duluth, Minn.

My dear Dr. Boyer:

Thank you very much for your fine letter containing not only the endorsement of your association but good advice for better procedure.

I have sent the letter to the editor of our state magazine asking that all of the letter be published so that your position may not be misunderstood nor misrepresented. Your letter will be read at the next meeting of our state board and I am sure will be very much appreciated.

Sincerely yours,
Mrs. Austin Mendenhall, *President.*

Secretary Meyerding read communications relative to the examination of children of pre-school age.

The Board of Education of the City of Duluth
Duluth, Minnesota.
May 1, 1930

Dr. S. H. Boyer, President,
Minnesota State Medical Association,
Lyceum Building,
Duluth, Minnesota.

Dear Dr. Boyer:

In connection with the examination of children of pre-school age, you may be interested in knowing that the office of the Attorney General has expressed the opinion that there is "no statutory authority which permits the use of the public funds of a school district for the medical or physical examination of children who are not attending the public schools," and that in reply to an inquiry made by the Commissioner of Education, as to whether it was lawful for a Board of Education to expend public money for medical or physical examination of children not attending the public schools, the reply was in the negative.

The opinion was issued April 28.

Very truly yours,
J. M. Robinson.

Dr. C. L. Haney (Duluth): We put that through the regular channels, through the school district of Duluth, through the Commissioner of Education, and through the Atorney-General's office. We knew pretty well beforehand we were going to get this opinion. After the P. T. A. reached the Attorney-General's office Mr. Phillips, the Assistant Attorney-General, practically reversed the decision, so the opinion reads now, I understand, that school children who are to enter school this fall can be examined. That is practically a reversal of the Attorney-General's opinion. That leaves it wide open. You can examine those who are entering school this fall. When we had this first opinion of course we had it all tied up.

President Boyer: You have heard the report, gentlemen. Are there any remarks or any discussion at all? What will you do with the report?

Dr. Albert G. Schulze (St. Paul): I move it be accepted.

Dr. J. R. Manley (Duluth): I second it.

President Boyer: If there is no objection, it will so stand.

The next order of business is the election of officers. Are there any nominations for the office of President?

Dr. O. E. Locken (Crookston): Mr. President and Members of the House of Delegates: In the past few years this Association has taken on a very intensive program of legislative and educational activities, and in order to carry on that work they have found it advisable to select the man for the office of president from the group of men who have been most active in doing that work, and that has been a very wise policy. Because of the many activities of the organization it has been nccessary to have someone who is not only a man of distinction in our Association but also a man who really knows the problems and purposes of the Association. From time to time the Association has gone outside of the two large cities and Rochester to select some member of our Association from the rural sections.

Today we feel that that is a wise policy to follow. It has now been five years since the Association has selected such a man. I am very happy to have the privilege today to make the nomination of that very likeable gentleman and honorable member of our Association, Dr. L. Sogge of Windom, a man who I am sure we can say has a multitude of friends and not a single enemy. I nominate Dr. L. Sogge of Windom. (Applause.)

Dr. R. C. Farrish (Sherburn): I take very great plcasure in seconding the motion.

Dr. N. O. Pearce (Minneapilis): In the name of Hennepin County delegation, from one of the large cities of the organization, it gives me great pleasure to second the nomination of Dr. Sogge.

President Boyer: Are there any other nominations?

Dr. F. H. Magney (Duluth): I move the nominations be closed.

The motion was seconded.

President Boyer: I don't think that should be rushed in a hurry. Are there any other nominations?

Dr. G. S. Wattam (Warren): I move that the Secretary be instructed to cast the ballot of this House of Delegates for Dr. Sogge of Windom as our next President.

President Boyer: Apparently there were no other nominations. Therefore, the motion is in order.

The motion was seconded and carried.

Secretary Meyerding: I hereby cast the unanimous ballot for L. Sogge as President for the ensuing year. (Applause.)

President Boyer: I appoint Dr. Locken and Dr. Wattam as a committee of two to escort Dr. Sogge into this chamber.

The next order is that of nominations for First Vice President.

Dr. W. W. Will (Bertha): A few years ago I was privileged to nominate a Vice President. This man was elected and proved to this Association that a Vice President can be of value to an association. That man later becamc the President of the Association and proved to be one of the greatest prcsidents this Association has ever had. I am not taking any credit for the man who was selected. I have in mind now a man for Vice President who I believe can render in cither office a like service, a man who has been untiring in his efforts in behalf of this Association.

Inasmuch as we have just elected a President from the country, and inasmuch as probably the next year's meeting will be in Minneapolis, it seems wise that we should select a Vice President from the city of Minneapolis. With that in mind, I have great pleasure in presenting the name of William H. Condit of Minneapolis for First Vice President. (Applause.)

Dr. Albert G. Schulze (St. Paul): I second it.

Dr. W. A. Fansler (Minneapolis): As delegate from Minneapolis I wish to second the nomination and say that the delegates from Minneapolis will be very happy to have Dr. Condit as our First Vice President, and feel it is an honor to Dr. Condit and to the Hennepin County Medical Society if he is elected.

President Boyer: Are there any other nominations.

Dr. W. F. Maertz (New Prague): I make a motion that the Secretary cast the unanimous ballot of the House.

The motion was seconded and carried.

Secretary Meyerding: I hereby cast the unanimous ballot for Dr. Condit as First Vice President.

President Boyer: Next in order is the Second Vice President. Nominations are in order. We have to have a Second Vice President, gentlemen. Does anybody want the job?

The audience arose and applauded as Dr. Sogge came forward.

President Boyer: It is hardly necessary to introduce the new President-Elect, but I shall call upon him to express himself as he sees best.

President-Elect Sogge: Gentlemen, I wish I were in possession of words that could in a slight degree express my appreciation of an act of this kind. Sunday night when I got in here somebody approached me and suggested that I serve as President for the coming year. I told him it was absolutely impossible; I could not fill that placc. In the first place I did not deserve the honor and further I was not capable. This man told me that I was in the hands of my friends and that they had done considerable work along that line and I could not refuse. I feel, folks, that if I am to take this job I want to feel that I am in the hands of my friends and they have got to help me. I feel, with the competent Secretary that we have, we may get along, and the work will undoubtedly be done by him. I thank you from the bottom of my heart for the honor. I appreciate the honor, but I also realize the responsibility. Thank you. (Applause.)

President Boyer: I wish to assure Dr. Sogge that judging by past performances of the members of this Association and its officers, he will not lack for support in his efforts to continue the success of this Society.

The Second Vice President is still begging for an office.

Dr. F. J. Savage (St. Paul): I would like to place the name of Owen Parker of Ely in nomination for Second Vice President.

Dr. G. S. Wattam (Warren): I second it.

PRESIDENT BOYER: Are there any other nominations? If not, we will proceed to cast the ballot.

The motion was carried.

PRESIDENT BOYER: Next is Secretary. Do you want a new Secretary? (Laughter.) Please make a motion, somebody.

DR. C. L. SCOFIELD (Benson): I move that the nominations be closed (laughter), and that the President be instructed to cast the vote of the Society for Dr. Meyerding.

PRESIDENT BOYER: Are there any objections?

DR. H. M. WORKMAN (Tracy): I should like to say, Mr. President, that this is a great chance to economize. If we start in with a new Secretary he can do it with a good deal less money. (Laughter.) I will second the nomination. (Laughter.)

PRESIDENT BOYER: The ballot is hereby cast for Dr. Meyerding. (Applause.)

Would you like to talk, Dr. Meyerding?

Next in order is the election of a Treasurer.

DR. H. J. ROTHSCHILD (St. Paul): I take great pleasure in nominating Dr. A. G. Schulze to succeed himself as Treasurer of this Association for the ensuing year.

DR. C. P. ROBBINS (Winona): I move the Secretary cast the ballot.

PRESIDENT BOYER: It has been moved and seconded that the Secretary cast the ballot for Dr. A. G. Schulze as Treasurer.

The motion was carried.

SECRETARY MEYERDING: I hereby cast the ballot for A. G. Schulze as Treasurer. (Applause.)

PRESIDENT BOYER: We must proceed with the election of Councilors. Four are to be elected. There will be a vacancy shortly in the Fourth District. That vacancy must be filled. The present incumbent is Dr. F. A. Dodge of Le Sueur.

DR. M. S. HENDERSON (Rochester): Mr. Chairman and Members of the House of Delegates: Brother Dodge has been a member of this Council for twenty-eight years, and everybody in the Association has known him and respected him, and he now says he has had enough, and I think his wishes must be respected as much as we would like to have him serve in office. I would like to suggest the name of a man who has been active in all organized medicine and stands high in the profession, Dr. Holbrook of Mankato.

DR. W. F. MAERTZ (New Prague): I second the nomination.

PRESIDENT BOYER: Any other nominations?

DR. E. M. HAMMES (St. Paul): I move nominations be closed.

The motion was seconded and carried.

DR. W. C. PORTMANN (Jackson): I move the Secretary cast the ballot.

DR. G. S. WATTAM (Warren): I second the motion.

PRESIDENT BOYER: If there are no objections he is so instructed.

SECRETARY MEYERDING: I hereby cast the ballot for Dr. Holbrook as Councilor of the Fourth District.

PRESIDENT BOYER: We will now proceed to the Sixth District. The present incumbent is Dr. Condit of Minneapolis. He is now First Vice President, leaving a vacancy in the Sixth District. These are all officers-elect, because it is the first of the year that the change takes place.

DR. W. P. GREENE (Minneapolis): We have a man in Minneapolis who has very well proven himself as far as taking interest in the work of the State Association and particularly the local association is concerned. He is a man who is untiring in his efforts in promoting medical matters in the state and he has proven himself to be a live wire in every respect. I take great pleasure in nominating Dr. N. O. Pearce to succeed Dr. Condit.

DR. E. S. BOLEYN (Stillwater): I second the motion.

PRESIDENT BOYER: Are there any other nominations?

DR. H. M. WORKMAN (Tracy): I move that nominations be closed and the Secretary be instructed to cast the ballot.

The motion was seconded and carried.

SECRETARY MEYERDING: I hereby cast the ballot for Dr. N. O. Pearce of Hennepin County as Councilor of the Sixth District.

PRESIDENT BOYER: Dr. Pearce is duly elected. The Eighth District. G. S. Wattam is the present incumbent.

DR. A. D. HASKELL (Alexandria): It gives me great pleasure to offer the name of the present incumbent, Dr. Wattam of Warren, Minnesota.

DR. G. S. WATTAM (Warren): Mr. President, I deeply appreciate the fact that the delegate from my Councilor District has again placed me in nomination as Councilor. I have had great pleasure in serving with the present members of the Council for the past six years. It has been a pleasant duty for me but I feel that my age and the location that I have in my district make it very inadvisable at this time that I accept that nomination, and with the consent of the delegate, and no rebuttal, I would like to place in nomination a man whom you all know and who will serve you to better advantage than I can or have. I place in nomination Dr. Hagen of Moorhead.

DR. A. D. HASKELL (Alexandria): It has been the custom for us to abide by our Councilors' decisions. I will withdraw my motion.

DR. G. S. WATTAM (Warren): I would like to place in nomination Dr. O. J. Hagen of Moorhead.

PRESIDENT BOYER: It has been moved and seconded that O. J. Hagen be elected as Councilor of the Eighth District. Are there any other nominations?

It was moved, seconded and carried that the Secretary cast the ballot.

SECRETARY MEYERDING: I hereby cast the ballot for O. J. Hagen of Moorhead as Councilor of the Eighth District.

PRESIDENT BOYER: Dr. Hagen is duly elected.

Dr. Sogge has been a member of the Council for a good many years. His term would normally expire in 1933. His unexpired term must be filled.

DR. E. S. BOLEYN (Stillwater): I nominate William A. Piper of Mountain Lake.

The motion was seconded.

PRESIDENT BOYER: Are there any other nominations?

It was moved and seconded and carried that the Secretary cast the ballot.

SECRETARY MEYERDING: I hereby cast the ballot for Wm. A. Piper of Mountain Lake as Councilor of the Second District to fill the unexpired term of Dr. Sogge.

PRESIDENT BOYER: It is customary for the Council to present to the House of Delegates the names, or nominees for delegates to the House of Delegates in the American Medical Association. The names the Council have submitted are those of Dr. H. M. Johnson and Dr. W. F. Braasch. They will be elected for a period of two years providing the nominations of the Council meet with the approval of this body. This body is at liberty to make additional nominations if it be so inclined. What is your pleasure?

DR. E. S. BOLEYN (Stillwater): I move that the nominations of the Council be accepted.

DR. J. R. MANLEY (Duluth): I second it.

The motion was carried.

PRESIDENT BOYER: Two names for alternates were submitted by the Council, Dr. B. S. Adams and Dr. O. J. Hagen. Dr. Hagen has been elected to the Council. Therefore he will not be able to serve as an alternate delegate to the American Medical Association.

DR. W. F. BRAASCH (Rochester): In view of the fact that Dr. Hagen is a Councilor, there is no legal objection to it, and while he is unquestionably a very good man for this position, I wonder if it wouldn't be good policy, possibly, to spread the office around a bit. Therefore, in view of Dr. Hagen's name I would like to nominate Dr. W. L. Burnap as alternate. He already has had considerable experience in that field.

DR. G. S. WATTAM (Warren): I second the motion.

PRESIDENT BOYER: Are there any other nominations?

The motion was carried.

PRESIDENT BOYER: Dr. Burnap is then one of the candidates for the position of alternate. The two names standing for election are Drs. Adams and Burnap. What will you do with these nominations?

DR. W. A. COVENTRY (Duluth): Mr. President, I move that the Secretary be instructed to cast the ballot of the House of Delegates for Dr. Johnson and Dr. Braasch as delegates and Dr. Adams and Dr. Burnap as alternate delegates to the American Medical Association.

The motion was seconded and carried.

SECRETARY MEYERDING: I hereby cast the unanimous ballot of delegates to the American Medical Association and alternates as follows: H. M. Johnson and W. F. Braasch as delegates, and B. S. Adams and W. L. Burnap as alternates.

DR. J. R. MANLEY (Duluth): There has been one more new resolution submitted to the Reference Committee.

Dr. Manley read the resolution.

RESOLUTION

The Washington County Medical Society in regular monthly meeting, April 13, 1930, voted unanimously that the Secretary of this Society should draw up a resolution in regard to certain matters specified in said Resolution and present same to the President of the Minnesota Medical Association. The Resolution of said Society follows:

Be it resolved, that, whereas, numerous interests are constantly requesting or demanding from the regular medical profession free service, for example, general physical examinations and toxin-antitoxin administration to pre-school children, service the profession should be paid for, inasmuch as said service is of distinct benefit to whom rendered; and further, that such requests or demands are by this Society regarded as wedges toward state medicine; therefore, be it resolved, that this Society does request the Minnesota State Medical Association to take some steps or action toward uniform and fair basis for a satisfactory solution of these or similar questions now before us or coming up in the future. It is understood that this Society is in accord with the whole regular medical profession, that any attention will be cheerfully rendered, free of charge, in case of inability to pay. It is further resolved that these different agencies should be informed when requesting any free service that the regular medical profession does more real charity work than any other class. Be it further resolved that a copy of this Resolution be forwarded to Samuel H. Boyer, M.D., President of the Minnesota State Medical Association. Adopted at Stillwater, Minnesota, May 13, 1930.

WASHINGTON COUNTY MEDICAL SOCIETY
WADE R. HUMPHREY, M.D., *President*
E. SYDNEY BOLEYN, M.D., *Secretary.*

DR. MANLEY: The Committee recommends the acceptance of the resolution.

PRESIDENT BOYER: You have heard the resolution. The Committee recommends the acceptance thereof.

DR. MANLEY: I move that.

DR. G. S. WATTAM (Warren): I second the motion.

PRESIDENT BOYER: Is there any discussion? An expression of opinion really ought to be had on that, even though there be no dissenting opinion.

DR. E. S. BOLEYN (Stillwater): It was felt that we would like to have uniform action by the whole Society as to how we should deal with these different examinations. Some people have been trying to get this and that for nothing and notably the Parents-Teachers Association have been trying to get a meeting and place the matter before us. We have had two meetings. We have lost two programs because they didn't come. They first intimated if we didn't do that they would appoint somebody to do it. Next they wanted us to appoint one or two men from the Society to do these examinations. We have objected to that because experience at large seems to be that men appointed to do those examinations at schools have demanded they be done at schools. That is not the way to do it. The best way to do it is to have a family physician make the examinations and do them in the office so as to take sufficient time to give them the proper service they are entitled to. We would like to have the Society appoint a Committee to draw up some sort of a program for the examination and that it be accepted and that the school boards could give these blanks to the children, or the parents before the schools are opened, and they could go to the family physician and be examined, and those who come up for examination be notified it would be advisable to have their children examined. We also made a ruling that those who

could pay would be charged $5 for each child, and that those who could not pay would receive the service free.

PRESIDENT BOYER: Any further discussion?

The motion was carried.

PRESIDENT BOYER: The recommendations of Dr. Boleyn can be referred and will be referred to the Public Health Education Committee, which Committee we think can handle that very satisfactorily.

SECRETARY MEYERDING: Yesterday an amendment to the By-laws was submitted which reads as follows: "Resolved that Chapter IX, Section 1, be amended by striking out the words 'A committee on Necrology' and that the duties of this committee be transferred to duties of the Historical Committee."

DR. H. M. WORKMAN (Tracy): I move the adoption of that.

The motion was seconded and carried.

PRESIDENT BOYER: Have you any unfinished business?

DR. H. M. CONNER (Rochester): In twenty-eight years as Councilor, the case of Dr. Dodge should be recognized by the Society by a vote of thanks. I therefore move that this Society extend a vote of thanks to Dr. Dodge for his services these twenty-eight years.

The motion was seconded and the audience arose and applauded.

PRESIDENT BOYER: Next is time and place of the next meeting. Where are we going to meet next year?

DR. N. O. PEARCE (Minneapolis): In behalf of the Hennepin County Medical Association and the people of Minneapolis I want to offer an invitation for this organization to meet in Minneapolis for their next annual meeting. (Applause.)

The motion was seconded and carried.

PRESIDENT BOYER: The time of meeting had better be left to the decision of the Council, because they might have to change the time. They can't tell just when is the best time. Will someone make a motion as to the time?

DR. W. A. COVENTRY (Duluth): I move the time of the next annual meeting be left to the discretion of the Council.

The motion was seconded and carried.

PRESIDENT BOYER: A Committee is to be appointed to present the President-Elect at installation Wednesday morning at ten a. m. The Committee that escorted him in will be appointed to perform that function, Dr. Locken and Dr. Wattam.

A motion is in order to present resolutions of thanks to the St. Louis County Medical Society, Hotel Duluth, Duluth Chamber of Commerce, Duluth Tribune, and Duluth Herald. You can appoint the Secretary to do that if you wish. If there is no objection we will so act.

DR. G. S. WATTAM (Warren): I would so move.

PRESIDENT BOYER: It is all settled.

DR. C. P. ROBBINS (Winona): I offer this resolution to the House of Delegates: That the delegates meet a day before the regular convention so that the delegates can enjoy the program of the convention.

The motion was seconded.

SECRETARY MEYERDING: I would like to call to your attention to the By-Laws: "The House of Delegates shall meet at two p. m. on the first day of the annual session." I suppose we could start our annual session with the House of Delegates meeting, couldn't we? I don't know how to interpret that. I think if you are going to change it you should make it to meet in the morning so that we can get through with it in one day.

The By-laws and Constitution provide: "The House of Delegates will meet at two p. m. on the first day of the annual session. It may adjourn from time to time as may be necessary to complete its business provided the hours conflict as little as possible with the general meetings. The order of business shall be arranged as a separate section of the program."

We have to meet two different days. "The election of officers shall be the first order of business of the House of Delegates after the reading of the minutes at the second meeting of the House of Delegates." It doesn't say the day after. They can meet in the morning or the afternoon.

DR. H. M. WORKMAN (Tracy): I think the trouble comes right here. The House of Delegates used to meet on the first day, then there were two days of scientific work, but a year or so ago we conceived the idea we wanted three days' scientific work. Dr. Robbins' suggestion means that we have to have a four-day session. The Council has already met twice.

DR. C. P. ROBBINS (Winona): Is it possible that the annual session can begin with the House of Delegates? I don't see why the House of Delegates can't meet a day before the regular scientific program.

DR. S. H. BAXTER (Minneapolis): I move you refer this resolution to the Council to discuss the feasibility of it and iron out the conflicts if there are any and arrange the program that way if possible, and leave it to their discretion.

PRESIDENT BOYER: Do you accept that as an amendment, Dr. Robbins?

DR. ROBBINS: I do.

The motion was seconded and carried.

PRESIDENT BOYER: Any other new business?

DR. W. F. BRAASCH (Rochester): I am sure we all are unanimous in feeling that the members of the St. Louis County Medical Society have fairly outdone themselves in the matter of hospitality, entertainment for the members, not alone the House of Delegates but our entire Association. I move that we express our appreciation of the efforts by a rising vote of thanks.

The audience arose and applauded.

SECRETARY MEYERDING: The Council will meet in this room immediately after the adjournment of the House of Delegates.

PRESIDENT BOYER: Is there any other new business? If not, a motion to adjourn is in order.

On motion regularly made, seconded and carried, the House of Delegates adjourned at three o'clock.

SCIENTIFIC PROGRAM

The scientific program was presented as published in the July number of MINNESOTA MEDICINE with the following omissions and additions.

Dr. Morris Fishbein, editor of the A. M. A. Journal, followed the other speakers at the Medical Economics meeting Monday evening.

Dr. W. J. Mayo spoke extemporaneously on the Diagnosis of Cancer of the Rectum in place of Dr. A. C. Strachauer, who was unable to be present.

The paper on Extra-Uterine Pregnancy by Dr. J. C. Masson, was read by Dr. W. N. Graves, the author having been unable to attend.

Professor Lorenz Boehler presented an additional moving picture demonstration portraying treatment of Fracture of the Os Calcis on Tuesday afternoon.

Dr. R. E. Farr being unable to attend the meeting, his paper on Local Anesthesia was read by Dr. W. N. Graves.

Following the Installation of Officers Wednesday morning, Dr. O. W. Parker presented the following report of the Committee appointed to award the gold medal offered by the Southern Minnesota Medical Association for the best scientific exhibit:

The Committee on Scientific Exhibit Award, having thoroughly studied all the exhibits from the standpoint of originality, practicability and manner of presentation, recommends that the Southern Minnesota Medical Association Medal for the best scientific exhibit at the annual meeting of the State Medical Association held at Duluth in 1930, be awarded to Dr. Leo G. Rigler of Minneapolis and his associates, for their demonstration of "Roentgen Studies of Free and Encapsulated Pleural Effusions," and that honorable mention be given to Dr. G. K. Wharton of Rochester, for his excellent and original work and beautiful slides and drawings of the blood supply of the pancreas with special reference to the blood supply of the Islands of Langerhans.

The Committee further commends the Southern Minnesota Medical Association for the gift of this medal, as it will be a definite stimulus for the development of original research work by the members of our Association.

Arnold Anderson
B. J. Clausen
T. G. Clement
F. J. Hirschboeck
O. W. Parker
E. M. Hammes, *Chairman.*

Dr. Leo G. Rigler was then presented with the medal by Dr. Parker.

The papers presented will for the most part be published in succeeding numbers of Minnesota Medicine.

THE EFFECT OF RADIANT ENERGY ON SKIN TEMPERATURE

The Public Health Service in conducting studies relating to industrial hygiene has recently completed a report dealing with the effect of radiant energy on skin temperature. This report describes the instruments that were devised and employed in these studies to determine radiant energy and skin temperature. A general picture of the results obtained has also been given as an indication or sample of the relationship between skin temperature, radiant energy, and the atmospheric conditions among steel workers. The final comparisons have been left to a later monograph which will show what correlations may appear between conditions found and the sickness rates, primarily pneumonia.

The following points have come out rather clearly in this preliminary analysis:

1. Intense sources of radiant energy had a pronounced effect on the skin temperatures of workers exposed to them; the forehead and cheeks showed the greatest increase.
2. Great differences in the skin temperatures of different parts of the body, for a single individual, were found in workers exposed to radiant energy.
3. Even under relatively cold atmospheric conditions, not far above the freezing point, high skin temperatures were encountered in workers exposed to radiant energy.
4. For workers not exposed to radiant energy there was a definite relation between atmospheric conditions and skin temperatures, both for arduous and for moderate work; the skin temperatures increasing with increase of effective temperature.

MEDICAL SERVICE IN FEDERAL PRISONS

On May 13, 1930, the President approved an Act of Congress which authorized the United States Public Health Service to provide medical service in Federal penal and correctional institutions under the Department of Justice. Henceforth the medical and psychiatric work in Federal prisons will be supervised and furnished by personnel of that Service. This new legislation is considered important in the field of penology and mental hygiene, and is part of the program for improving the conditions in Federal prisons, and also an effort to promote uniformity in the medical work of the Federal Government.

It is obvious that important medical problems arise in connection with the detailed care of Federal prisoners and that the medical service of a modern prison involves certain routine procedure and also certain research activities, the latter relating directly to the solution of medical administrative problems and to increasing the sum of knowledge concerning technical medical questions. The routine requirements of a prison medical service involve the psychiatric examination and classification of prisoners and the treatment and supervision of all mentally diseased inmates. It also involves the conduct of physical examinations sufficient in scope to permit of the prompt recognition and correction of physical defects and diseases. All the necessary facilities for reasonably meeting these requirements are largely technical or administrative medical questions.

The psychiatric examination and classification of inmates is of very great value to those concerned with the application of disciplinary measures; with the protection of the mentally disordered inmate; with the protection of other inmates and employees; with the treatment of prisoners generally; with the transfer of mentally disordered persons to institutions most suited to give specialized care; and with the subject of parole and discharge of inmates. A more intimate knowledge of the mental characteristics of prisoners should contribute to a better understanding of several features involved in correctional systems generally; to the necessity for specialized methods in care and procedure; and to the evolution of institutional facilities to meet requirements applicable to specific types of cases. Such a program will intimately dovetail with other activities of the prison, having for their object individual care, supervision, and disposition of inmates.

It is obvious that the inmates of prisons are subject to the same intercurrent physical and mental illnesses, diseases, or defects, as are seen among those that comprise the general population. A properly organized prison medical service, therefore, must be both general and special in character to meet these needs.

A well-organized medical service in a modern prison can contribute to the welfare of inmates and employees in ways other than those mentioned, by rendering advice and counsel respecting sanitation and personal hygiene; by helping to organize and guide recreational, educational, occupational, and vocational activities with a view to promoting the health of both inmates and employees; and by giving assistance and advice for maintaining a wholesome and well-balanced dietary.

It is obvious that the chief medical officer of a large modern prison has an important and specialized duty to perform, and one requiring special training, administrative ability, tact, and judgment, and that adequate assistance is necessary for him to meet the demands of a well-balanced medical service.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

EXAMINATION REPORT, APRIL, 1930

CANDIDATES BY EXAMINATION

Name	School and Date of Graduation	Address
Auld, Irving	Northwestern, M.D., 1929	317 E. 5th St., Duluth, Minn.
Brown, Robert Whitcomb	Harvard, M.D., 1928	Mayo Clinic, Rochester, Minn.
Burkley, George Gregory	U. of Pittsburgh, M.D., 1928	Mayo Clinic, Rochester, Minn.
Caldwell, John Mars, Jr.	U. of Georgia, M.D., 1928	Mayo Clinic, Rochester, Minn.
Carlson, Hjalmar Edwin	U. of Minn., M.B., 1929	1038 Matilda St., St. Paul, Minn.
Castleton, Kenneth Bitner	U. of Pa., M.D., 1927	Mayo Clinic, Rochester, Minn.
Chor, Herman	U. of Maryland, M.D., 1928	Mayo Clinic, Rochester, Minn.
Espersen, R. Wayne	U. of Minn., M.B., 1929	251 Drake Road, Bend, Oregon
Grimes, Allen Evans, Jr.	Northwestern, M.D., 1928	Mayo Clinic, Rochester, Minn.
Happe, Lawrence John	Creighton, M.D., 1929	Marshall, Minn.
Herbert, Willis Leo	Creighton, M.D., 1929	Maynard, Minn.
Herbst, Kenneth Albert	U. of Minn., M.B., 1929	Hastings, Minn.
Holmstrom, Carle H.	U. of Minn., M.B., 1929	St. Mary's Hosp., Duluth, Minn.
Humphrey, Arthur Allan	Northwestern, M.D., 1929	Mayo Clinic, Rochester, Minn.
Johanson, Waldemar G.	U. of Minn., M.B., 1930	627 E. Jessamine St., St. Paul, Minn.
Johnson, Arthur Bernhoff	U. of Minn., M.B., 1930	3606 Dupont Ave. N., Minneapolis, Minn.
Johnson, Herbert Paul	U. of Minn., M.B., 1929	1604 Elliot Ave., Minneapolis, Minn.
Jordan, Lewis Stanley	Eclectic Med. Coll., M.D., 1926 Cincinnati, Ohio	Riverside San., Granite Falls, Minn.
Jorris, Edwin Hall	U. of Minn., M.B., 1929	St. Mary's Hosp., Duluth, Minn.
Knapp, Miland Elbert	U. of Minn., M.B., and M.D., 1929	1538 Hillside Ave. N., Minneapolis, Minn.
Knight, Homer Holcomb	U. of Minn., M.B., 1929	General Hospital, Minneapolis, Minn.
Loucks, Milo M.	U. of Minn., M.B., and M.D., 1930	Pipestone, Minn.
Lynch, Francis W.	U. of Minn., M.B., 1929	University Hosp., Minneapolis, Minn.
McLane, Evelyn Gruhlke	Rush, M.D., 1930	Sleepy Eye, Minn.
Mark, Hilbert	U. of Minn., M.B., 1929; M.D., 1930	Akeley, Minn.
Messick, Joseph Marion	U. of Pa., M.D., 1928	Mayo Clinic, Rochester, Minn.
Murray, Robert Anthony	U. of Minn., M.B., 1929	St. Mary's Hosp., Duluth, Minn.
Olson, Clifford A.	U. of Minn., M.B., 1930	Swedish Hospital, Minneapolis, Minn.
Palmer, Bascom Willcox	Med. Coll. of South Carolina, M.D., 1928	Miller Clinic, Hamm Bldg., St. Paul, Minn.
Rademacher, Clyde J.	U. of Minn., M.B., 1929	Kimball, Minn.
Rice, Herbert R.	U. of Minn., M.B., 1929	3136 2nd Ave. S., Minneapolis, Minn.
Russell, Sidney Benteen	U. of Minn., M.B., 1929	St. Mary's Hosp., Minneapolis, Minn.
Ryan, Joseph Maurice	St. Louis U. Sch. of Med., M.D., 1929	St. Paul Clinic, St. Paul, Minn.
Sharp, Jay Emerson	Ohio State U., M.D., 1925	302 Furlow Apt., Rochester, Minn.
Smisek, Elmer Albert	U. of Minn., M.B., 1929; M.D., 1930	957 Arcade St., St. Paul, Minn.
Spooner, Alexander Dwight	U. of Wis., M.D., 1928	Mayo Clinic, Rochester, Minn.
Stenberg, Sherman T.	U. of Minn., M.B., 1929	2228 Seabury Ave., Minneapolis, Minn.
Swedenburg, Paul A.	U. of Minn., M.B., 1930	901 E. River Road, Minneapolis, Minn.
Tavenner, John Lyle	Northwestern, M.B., 1929	Waseca, Minn.
Taylor, James E. C.	Ohio State U., M.D., 1928	610 8th Ave. S. W., Rochester, Minn.
Vogel, Howard A.	U. of Minn., M.B., 1930	New Ulm, Minn.
Wahlberg, Elmer Waldor	U. of Minn., M.B., 1929	Isle, Minn.

CANDIDATES BY RECIPROCITY

Dierkes, Gustave J.	Creighton, M.D., 1917	Rollingstone, Minn.
Harmeier, John Watson	U. of Pittsburgh, M.D., 1928	Mayo Clinic, Rochester, Minn.

THE USE OF TANNIC ACID IN BURNS OF CHILDREN*

EDWARD C. DAVIDSON, M.D.
Detroit, Michigan

THE profound metabolic disturbance following a severe cutaneous burn has been the subject of extensive laboratory and clinical investigation. Theories have been offered that the reaction of the body to a thermal insult is due to a disturbance of one or another of the various functions of the skin, namely, respiration, excretion, sensation, or heat regulation. Others have attempted to explain the phenomenon observed on the basis of alteration in the blood, such as destruction of red cells by heat, concentration of the blood, inability to take up oxygen, stasis in the large vessels, and extensive thrombosis. The clinical course which follows such injuries cannot be attributed to interference with any of the functions of the skin, nor can it be ascribed to the known changes in the blood. These may be contributing factors, but in themselves they do not adequately explain the sequence of events which take place.

TOXEMIA THEORY

There is certain convincing evidence that suggests the formation at the site of the burn of a toxic substance, the absorption of which is responsible for the constitutional reaction. Reiss succeeded in isolating from the urine of burned patients a substance which was toxic to animals. Vogt observed that when parabiosis was established between two animals and one was burned, the other showed evidence of toxemia. Pfeiffer isolated cleavage products of protein decomposition from burned skin which were toxic. Robertson and Boyd have also demonstrated the toxicity of the products of protein autolysis of burned tissue. They further showed that the toxin circulated in the blood. Bardeen observed degenerative changes in the liver, spleen, kidneys, and bone marrow in a series of lethal cases. He further noted a general edema of all lymphoid tissue, which was most marked at the germinal centers. He concluded that the findings were best explained on the basis of an acute toxemia. Weiskotten and Olbrycht arrived at the same conclusion, but emphasized the degenerative changes in the adrenals. Of the various theories presented, therefore, that which attributes the constitutional reaction to absorption of some toxic substance or substances from the burned area is more strongly supported by the available evidence.

These facts suggest that the rational manner of combating the toxemia would be some form of local treatment which would prevent absorption from the site of the burn. Debridement has deserved a certain amount of popularity, but its application is limited by the severity of the procedure. Douglas attempted to retard the process of absorption by the use of the vaso-constrictor—adrenalin. Others have attempted to lessen the toxemia by the use of continuous tubs, hoping to remove the toxic material as promptly as it is formed. These methods have been efficacious to a certain degree, but have not altered the toxemia materially.

TANNIC ACID

It would seem that the rate of absorption might also be greatly lessened, if the tissue devitalized by the burn were exposed to a protein precipitant which would hold the decomposition products out of solution. Tannic acid accomplishes this purpose in forming more or less stable compounds with the burned tissue, which are relatively insoluble and are held upon the surface

*From the Department of Surgery of the Children's Hospital of Michigan, Detroit, Michigan. Presented before the annual meeting, Minnesota State Medical Association, Duluth, July 16, 1930.

instead of being absorbed into the general circulation. The precipitated proteins on the surface treated provide a protective coating against chemical, bacterial, and mechanical action as well as against sensory stimulation (Figs. 1 and 2).

Fig. 1. Case 1. Showing an extensive second and third degree burn of a child aged three years. The parchment-like covering is insensitive. Maintenance of dryness minimizes infection.

ETIOLOGY

The importance of the problem of burns in children is evidenced by the fact that 45 per cent of the lethal burns occurring annually in the United States, are in children under six years of age. In 62 per cent of the cases admitted to the Children's Hospital of Michigan during the past three years, the burn was due to someone leaving a pail of hot water unprotected (Figs. 3, 4, and 5), the filling of a bathtub with hot water, and the child falling into it, or due to a child pulling a kettle of hot water, soup or coffee from a stove, spilling the contents over itself (Figs. 6 and 7). This suggests that over 60 per cent of the mortality and morbidity of burns in children is definitely avoidable, and due to the negligence or carelessness of someone in leaving a pail of water unprotected or filling a bathtub with very hot water and waiting for it to cool, instead of drawing it at the desired temperature, or permitting a child to play around a stove on which something is cooking.

The second important causative factor is playing with matches or around a bonfire. Twenty-five per cent of our cases were of this origin.

Although boys and girls are similarly dressed during the first three years of life, more boys die of burns than girls. This may probably be attributed to the more venturesome spirit of boys which exposes them to greater danger. Statistics of the Metropolitan Life Insurance Company, covering a period of over twenty years, show that in the fourth year of life the relatively higher death rate of females from burns begins. The margin increases from five to nine years, when more than twice as many girls as boys die from this cause. This may probably be attributed to the type of clothing worn, because at all ages the morbidity is greater in boys.

Fig. 2. Case 1. Healing complete seven weeks after the injury. Pinch grafts were applied to upper chest. Thigh shows area from which grafts were cut.

PROGNOSIS

Several important papers have recently been published giving statistical data about the change in mortality from burns in children since the adoption of the tannic acid method. Harris has reduced the mortality from 26.6 per cent to 12 per

cent at the Sick Children's Hospital of Toronto. Herzfield has reduced the mortality at the Royal Edinburgh Hospital for Sick Children from 38 per cent to 9 per cent. Beckman has reported of death in all lethal cases before and after the introduction of the method now used, rather than from a study of the gross mortality percentages. This plan has been adopted.

Fig. 3. Case 2. Showing the characteristic lesion resulting from a child backing into an unprotected pail of hot water. These burns are generally of the second degree unless infection destroys the small islands of epithelium.

Fig. 4. Case 2. Healing complete three weeks after the accident.

Fig. 5. Case 3. Showing a third degree burn resulting from backing into a pail of water. This area was grafted in the presence of infection and the wound was not dressed for six days. A satisfactory take is shown.

Fig. 6. Case 4. Showing a second degree burn resulting from pulling a kettle from the stove. Child aged eighteen months.

Fig. 7. Case 4. Showing final result, four weeks later.

a reduction of the mortality at Bellevue Hospital from 27.8 per cent to 14.9 per cent. Because of the great variation in the severity of burns admitted from year to year, it would seem that a better index of the progress made would be obtained by the study of the time and cause

The prognosis in any given case of a burn in childhood must be guarded because of the profound metabolic upset which may occur. It has been stated that an adult may tolerate a burn involving one-third of the total body area and a child will tolerate one involving only one-seventh

of the total cutaneous area. It has further been stated that in regard to prognosis the extent is of more importance than the depth of the burn. This statement is true for immediate mortality,

Fig. 8 *(upper)*. Case 5. Showing a very extensive third degree burn of a child aged six years. Bands about four inches in width were grafted in stages starting on the chest and working downward. Finally each flank was grafted. Sufficient grafts were obtained from legs.

Fig. 9 *(lower)*. Case 5. Showing final result 103 days after the accident. Illustration reproduced from the 1929 Detroit Proceedings of the Inter-State Postgraduate Medical Association of North America.

but it is certainly not true for ultimate mortality in children.

The depth of a burn is determined by the temperature of the agent and the duration of the contact with the skin. It is well established that thick skin, as on the palms of the hands, offers a greater resistance to heat than the softer, more delicate skin of the protected parts of the body. The same applies to children, where the skin of the entire body is thinner, of softer texture, and more delicate than that over corresponding parts of the adult body. Accordingly, an intensity of heat applied to the skin of a child for a given increment of time may cause a third degree burn, while the same thermal stimulus on the thicker, more resistant skin of an adult may cause only a first or at most a second degree burn. For this reason, large, deep burns are seen frequently in children from what appeared to be a relatively slight thermal trauma. This may leave a large granulating wound which is very badly tolerated early in life, and is of grave prognostic significance (Figs. 8 and 9). Unless prompt epithelization is accomplished by skin grafting the picture of exhaustion develops and various complications occur. In the adult this problem does not arise, because the granulating wound is well tolerated and grafting is a simple procedure which may be done under local anesthesia. In children, the matter is a serious one because delay means the development of complications, while the risk of the procedure and its attending anesthesia is considerable.

Wilson has divided the clinical course of severe burns into four stages, which are descriptive of the underlying pathology at any given time, and are exceedingly helpful in arranging a rational therapy: (1) Shock; (2) acute toxemia; (3) septic toxemia; (4) healing.

SHOCK

When a child receives a burn of any great extent, shock almost invariably occurs. It is exceedingly difficult to state when shock ends and the true toxemia of burns begins. The skin becomes cold and clammy, the temperature falls, the pulse becomes rapid and weak, and sensibility is blunted. Cannon has presented a rather plausible theory of shock and concluded that it is due to the absorption of autolyzed protein from the site of the injury. Crile, on the other hand, emphasizes the stimulation of the sensory nerve endings. It would, therefore, seem reasonable to assume that any drug which would precipitate the protein devitalized by the burn and stop absorption and at the same time dull the exposed

sensory nerve endings would be effective, regardless of which theory one accepts. Tannic acid is such a drug.

Our method has been to place the child in a light tent on sterile sheets (Fig. 10). Open all blebs, carefully remove all loose tissue, and cleanse the denuded area as carefully as possible without excessive trauma. Time spent thoroughly cleansing the burn at this period minimizes subsequent infection. The burned area is then sprayed with a five per cent aqueous solution of tannic acid every fifteen minutes until the surface is a light brown color. This is generally accomplished in about two hours.

Underhill has shown that marked concentration of blood occurs and that if this is allowed to persist it is soon incompatible with life. It is known that hyperglycemia and at times glycosuria occurs during this initial period. It has also been established that the blood chlorides are markedly depressed. Because of these facts it has been our custom to give normal saline instead of glu-

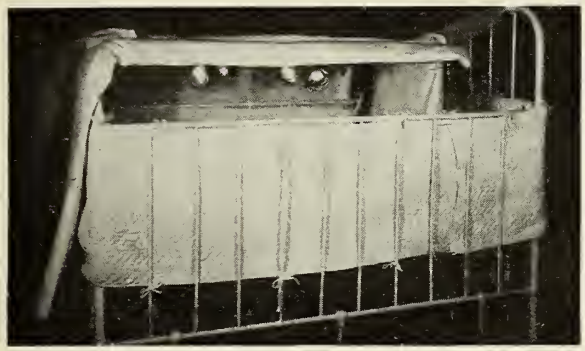

Fig. 10. Showing arrangement of bed. Sheet hung at head to protect eyes from light. Mosquito netting is shown thrown back. Lights are in position to furnish adequate heat.

Fig. 11. Case 6. Showing a second degree burn of a child three years of age. The coagulum has spontaneously separated from the buttocks, revealing complete healing.

Fig. 12. Case 7. Showing an extensive third degree burn in process of preparation for grafting. Area covered with a perforated cellulose non-adhering dressing over which compresses are placed.

Fig. 13. Case 8. Showing the wound after the area has been covered with pinch grafts. The extent of the wound into the axilla should be noted. Grafts cut from both thighs, entire back done at one stage.

Fig. 14. Case 8. Showing functional result one year later.

cose subcutaneously, intravenously, and per rectum promptly upon admission, as well as to force fluid by mouth.

It has further been demonstrated that the capillaries during this period are more permeable than normal and that blood plasma is lost into the tissues. If the burn is extensive, and it appears that shock will occur, transfusion is done in anticipation of shock and repeated if it occurs. It has been observed that these children tolerate relatively larger transfusions than those transfused for other conditions in which there is not such a great reduction of blood volume. These energetic measures have resulted in less vomiting, which materially simplifies the subsequent management. In our early experience the incidence of death from this origin in our lethal cases during the first 36 hours after the accident was 25 per cent. Although the cases of burns admitted to the hospital during the last two years have probably been quite similar in extent and severity there has been no mortality during the first 36 hours after the thermal insult from shock.

Fig. 15. Case 9. Showing the mobility of pinch grafted area with the development of a new subcutaneous tissue, which is attributed to doing the procedure early.

TOXEMIA

Should the individual survive the initial collapse, there is a later secondary toxemia. The temperature is quite elevated, the pulse is rapid and bounding, the skin is flushed, the psychic symptoms are those of a delirium, and muscular twitching and convulsions may be present. Vomiting may make the oral administration of fluids impossible. This syndrome generally occurs about thirty-six hours after the accident and persists about eight to ten days.

It has been shown that precipitation of the devitalized tissue with tannic acid limits absorption and prevents the loss of body fluids at the site of the burn by covering it with a parchment-like protective coagulum. It has further been observed that moistening this dried material immediately releases the toxic agent and causes a profound change in the patient. Because of these facts, the patient is kept in a light tent, on sterile sheets, and nothing further is done locally. The child is turned over to the nurses, whose duty is primarily to see that the intake of fluid is adequate.

Normal saline is given intravenously or subcutaneously daily in all extensive burn cases until the period of toxemia is past. Sedatives are given freely at night to insure rest, so that the day may be fully utilized for the administration of fluids. Thirty-three per cent of the lethal cases prior to our present method of management died of this origin. Since the adoption of these measures seventeen per cent of the lethal cases have died from the toxemia of burns.

SEPTIC TOXEMIA AND LATE TREATMENT

It has been observed that in second degree burns the coagulum acts as a splint and healing takes place beneath it and is generally complete at the end of two to three weeks (Fig. 11). Effort made to remove the coagulum before it has spontaneously separated has invariably resulted in the escape of serum and blood with subsequent infection due to moisture. Should the precipitated skin remain adherent at the end of three weeks, one may be certain that the burn is one of the third degree. It is relatively safe at this time to soak off small pieces of slough, but great care

must be exercised to avoid overwhelming the patient by releasing a large amount of toxin.

Children tolerate granulating wounds very badly. Cultures of these wounds generally show that the superimposed complication cannot be withstood.

In cases with large granulating wounds one is confronted with the danger of taxing the child

Fig. 16. Case 10. Showing characteristic deformity resulting from old burn of chest and neck. Chin-chest adhesions have formed and the anterior muscles of the neck have shortened. Large granulating wound with scar tissue base still present.

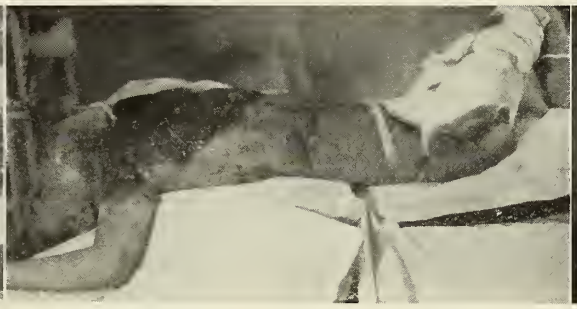

Fig. 17. Case 10. Debridement has been done of entire area. Pinch grafts applied to neck and upper chest.

Fig. 18. Case 10. Complete healing with correction of deformity. The cosmetic result remains to be taken care of later after the development of a new subcutaneous tissue under the graft.

Fig. 19. Case 11. Showing complete disability of both hands possibly aggravated by inadequate splinting and maintenance of separation of fingers.

Fig. 20. Case 11. Showing present stage of the correction.

the same organisms that are found on normal adjacent skin. Unless skin grafting is done promptly, the child develops the picture of exhaustion and succumbs, or some serious complication arises. Diarrhea, suppurative joints, otitis media, mastoiditis, pneumonia, pyelitis, septicemia, endocarditis, myocarditis, nephritis, as well as all the acute infectious diseases of childhood are seen with great frequency. It is our belief that many children are surviving the initial period during which they previously died, only to succumb later from some such complication. It is quite possible that the strength and resistance has been so impaired by the toxemia too greatly with the operation of skin grafting, but at the same time one must be aware that delay generally means a poorer surgical risk (Figs. 12, 13, and 14). As a result of this experience, we are grafting at the earliest possible date even in the presence of gross infection. This is generally accomplished in the third or fourth week after the thermal insult.

SKIN GRAFTING

It has been our custom to use pinch grafts for large denuded areas. These may be placed on an infected granulating area and still there is a reasonable chance for a successful take. Thiersch

grafts have been used on the exposed surfaces, because of the better ultimate cosmetic result.

It is desirable to skin-graft at the earliest possible date, not only to avoid exhaustion, but also

Fig. 21. Case 12. Showing the position maintained in burns of the axilla and arm to prevent the development of arm-chest adhesions.

to avoid contractures. When the grafting is done sufficiently early, a new subcutaneous tissue will form (Fig. 15). Contractures occur only when granulation tissue is permitted to heap up layer upon layer and subsequently to be covered with epithelium. Later this granulation tissue forms a scar tissue base which contracts and causes deformity. It is sometimes stated that a circular pinch graft of an extremity will later interfere with the venous and lymphatic return, and cause edema. This is true only if the granulation tissue is permitted to heap up previous to the grafting.

It is frequently found that a profound anemia has developed by the time the child is ready for grafting. The red blood cell count is rarely over three million per cubic millimeter, and the hemoglobin is usually under 50 per cent. It is desirable that the blood elements be restored to approximately normal by transfusion before grafting. Sluggish granulation tissue is remarkably improved by this procedure and the success of the graft insured.

DEFORMITIES

We frequently see old burns involving the chest and neck. The child has been permitted to have a pillow under the head. This invariably results in shortening of the anterior muscles of the neck with the development of chin-chest adhesions. In these cases it has been our practice to first correct the deformity by doing a complete debridement of the scar and granulating wound. The child is then placed on a Bradford frame with the head hanging downward (Figs. 16, 17, and 18). The wound is then covered with pinch grafts in an effort to obtain prompt epithelization. Six months to a year later the child is recalled and an effort made to get a satisfactory cosmetic result by the use of pedicle flaps, full thickness inlays or Thiersch grafts. The results obtained from these measures have been gratifying.

Fig. 22. Case 13. Showing method of correction after arm-chest adhesions have occurred. An anterior and posterior pedicle flap have been turned up to form a new high axilla.

Deformities of the hands in children are exceedingly common and in part are avoidable by proper splinting after the open method of treatment has been discontinued and the careful maintenance of separation of the fingers to prevent webbing. These measures often avoid the necessity of extensive plastic procedures which at times are exceedingly difficult (Figs. 19 and 20).

Burns involving the axilla are of great importance because of the serious disability caused by the formation of arm-chest adhesions. This deformity may largely be avoided by keeping the arm in abduction during the entire period of healing (Fig. 21). Should webbing occur, this may possibly be best corrected by dividing the web high into the axilla and turning an anterior and posterior flap into this newly formed axilla, and filling in the lower defect with either Thiersch or pinch grafts (Fig. 22).

CONCLUSIONS

1. The treatment of burns with tannic acid followed by exposure to air lessens toxemia.

2. Tannic acid as an initial dressing on a burn is analgesic.

3. The local astringent effect prevents the loss of body fluid.

4. Secondary infection is markedly limited by the absence of a favorable nidus for bacterial growth.

5. Scar tissue formation has been less marked than that observed after treatment by other methods.

6. The protective layer of coagulated protein forms a scaffold for the growth of the young epithelial cells over the denuded area.

SICKNESS AMONG INDUSTRIAL EMPLOYEES

In a report recently published the United States Public Health Service points out that an influenza epidemic was in progress during the final month of 1928, affecting adversely the rate of sickness in the fourth quarter of that year. For this reason the disability rate for the last three months of 1929 among a group of about 110,000 industrial employees makes a favorable comparison with the rate for the corresponding period of the preceding year. The frequency of disability from sickness lasting more than one week was 27 per cent lower in the fourth quarter of 1929 than in the same quarter of 1928. The respiratory group of diseases shows the greatest decrease, of course; the rate was little more than one-half that experienced in the last three months of 1928. Influenza and grippe decreased 64 per cent, and pneumonia 26 per cent from the incidence experienced during the fourth quarter of 1928. In the last three months of 1929, however, bronchitis and diseases of the pharynx and tonsils increased 13 and 9 per cent, respectively, but the incidence of tuberculosis declined 20 per cent, and the rate for respiratory diseases other than those mentioned above dropped 5 per cent from the rate of the fourth quarter of 1928.

It is quite possible that the recorded sickness presented above understates to some extent the real magnitude of the incidence rate of cases causing disability for more than one week, because a number of the reporting associations do not pay sick benefits for disability on account of the venereal diseases, for illness resulting from violation of any civil law, for the results of willful or gross negligence, and for certain other causes; and some associations do not pay for chronic diseases contracted prior to the date of joining the organization, for disabilities caused by or growing out of specific physical defects, nor for illnesses not reported within specified time limits. Of more importance, perhaps, is the fact that the reports come from the larger companies having well-organized employment and medical departments which make a physical examination of applicants, so that a somewhat favorably selected group from a health standpoint may result. Workers in poor health who doubt their ability to pass the physical examinations may tend to drift into the smaller industrial establishments where the physical condition of the applicant is usually given less consideration. As offsetting factors a few cases of malingering may be included in the records, and the associations with the most liberal sick-benefit provisions may attract persons when their health begins to fail. On the whole, it seems that the statistics presented may tend more toward understatement than overstatement of the average frequency of disability which lasts longer than one week among industrial employees.

THE EARLY DIAGNOSIS OF CARCINOMA OF THE STOMACH*

Leo G. Rigler, M.D.
Minneapolis

CARCINOMA of the stomach presents a more important problem to the medical profession than is generally recognized. An attitude of indifference toward this serious affliction is apparent due to an impression that gastric cancer is rare and, in any event, an almost hopeless condition. Both of these premises are grossly incorrect. Actually the disease is not rare and, if diagnosed early, can, in many cases, be cured.

Gastric cancer is the most frequent type of fatal carcinoma. For example, in the State of New York, in 1928, carcinoma of the stomach and liver was the cause of death in more than one-third of all the carcinoma fatalities. Its nearest competitor in this respect, cancer of the female genitalia, caused less than one-fourth of all the deaths from cancer. In some areas the frequency is even greater. Considered in another way, carcinoma of the stomach and liver represent the causative factor in 4.6 per cent of all the deaths of individuals over the age of forty-five. This compares strikingly with about 1.5 per cent for cancer of the uterus and ovaries, 1 per cent for cancer of the breast, and 4 per cent for cancer of the buccal cavity. A comparison of this figure of 4.6 per cent for carcinoma of the stomach with pneumonia, which represents 3.8 per cent of deaths past the age of forty-five, or diabetes, which represents 2 per cent, indicates strikingly the grave importance of this disease as a cause of death. One out of every twenty-two deaths over forty-five years of age is due to cancer of the stomach or liver.

There is only one form of treatment for carcinoma of the stomach which holds out any reasonable hope of cure—radical surgery. This can only be effective in the cases which are diagnosed at an early stage and this is the problem which confronts us.

There are three major difficulties which prevent the early diagnosis of this condition. The first is the insidious character of the disease. There is hardly a condition which may progress so far with so little warning as carcinoma of the stomach. It is true that the patient usually has symptoms, but these are so similar to the gastric upsets which are such a common part of everyone's life that little or no attention is paid to them. The average individual finds a host of comparatively innocent reasons to account for the feeling of fullness after eating, loss of appetite, gas eructations, and slight epigastric distress which may be the very first symptoms of carcinoma. Too often attention is directed to decayed teeth, dietary indiscretions, nervousness and overwork, while the organic gastric disease is overlooked. In those cases where the lesion arises in the pylorus or near it, producing early obstruction, the symptoms are more striking and medical aid may be sought at an early stage.

The second factor of delay is due to the character of the patient. Poverty, ignorance, prejudice, or fear may prevent an individual who has severe symptoms from consulting a physician. Too often the cancer patient has gone to some type of quack or has taken some type of patent medicine before attempting to obtain competent medical advice. Frequently the fear of cancer actually keeps the sufferer from consulting a physician because he does not want to hear the truth.

These two factors have led to much of the anti-cancer propaganda which has been so widely disseminated amongst the public in the past few years. Although this educational campaign serves a very good purpose, it should really be made secondary to an educational campaign directed to the medical profession itself.

For it is in the physician that the third major difficulty in the early diagnosis of gastric cancer lies. Even if a patient comes to a regular practitioner when his lesion is in an early stage, the chances are extremely good that it will not be recognized and that dangerously dilatory treatment will be given until it

*From the Departments of Roentgenology of the University of Minnesota and the University Hospital, Minneapolis, Minnesota. Read before the Minnesota State Medical Association, Duluth, Minnesota, July 15, 1930.

is too late. This is the problem which the medical profession faces. There is no great benefit in urging the layman to consult a physician when he has symptoms of cancer of the stomach if the physician does not recognize the condition when he sees it. Dr. Jacob Sagel and I have been making an intensive study of the histories of all the cases of carcinoma of the stomach which have presented themselves at the University and Minneapolis General Hospitals during the past year. In this series the patients had consulted a doctor within three months, on the average, after the onset of recognizable symptoms. The diagnosis, however, had been delayed from six months to two years after the physician had been called in. This delay was due to either inadequate examination or the inability of the practitioner to recognize the findings in gastric carcinoma. Likewise no adequate treatment had been given, with the result that the majority of cases seen were inoperable. The medical histories of these patients represent a serious indictment of the medical profession. They indicate clearly that cancer of the stomach is not being taken seriously enough by the average physician and that he is making no great effort to further its early diagnosis. On the contrary there appears to be a tendency to give drugs such as alkalies or hydrochloric acid and watch the patient for long periods of time until the symptoms and signs are unmistakable.

How can the diagnosis of carcinoma of the stomach be made in an early stage? In the later stages, the marked loss of weight, cachexia, palpable mass, vomiting, often bloody, serve frequently to identify the disease without elaborate procedures. But the diagnosis at this stage is worth very little to the patient as surgery will probably be ineffectual. In the early stages, on the other hand, the physical examination is usually negative. The history, if carefully taken, may be suggestive of carcinoma, but a diagnosis on the history alone is hardly possible and would lead to numerous errors both positive and negative. The best method of diagnosis is by a competent *x*-ray examination. In experienced hands, this is one of the most accurate procedures in medicine. Such statistics as have been presented by Carman, from the Mayo Clinic, or Merrill, from the Massachusetts General Hospital, indicate that the diagnosis can be correctly made by the roentgen method in 92 to 98 per cent of the cases. Obviously this diagnostic accuracy is greater than could be achieved under averaage conditions, but it indicates the possibilities of the method.

Unfortunately all patients who come to the physician complaining of gastric symptoms cannot be given a roentgen examination. It would hardly be, either economically or socially, feasible. Some selection must, therefore, be made. First of all, every patient past the age of forty who has gastric complaints should be looked upon as a cancer suspect. Most of them will not have carcinoma, it is true, but for the sake of those that do we must examine all of them with the greatest care. The age limit is placed at forty because the vast majority of cases occur past this age, but we must bear in mind that carcinoma of the stomach occasionally occurs in much younger persons also.

In these case, at least, in addition to the usual examinations, two procedures should always be undertaken. The first is a gastric expression with determination of the presence or absence of free hydrochloric acid; the second, an examination of the stools, under proper conditions, for occult blood. Neither of these tests are pathognomonic, but both are comparatively simple and can be done by any physician in his office. Therein lies their value. The presence of free hydrochloric acid in the gastric contents does not rule out carcinoma of the stomach, but makes its presence somewhat less probable. The absence of free hydrochloric acid in the gastric contents, especially if the histamine test has not been used, is also not of any great significance, yet it makes it more probable that carcinoma of the stomach may be present. Likewise the absence of blood in the stools does not rule out gastric cancer but makes its presence somewhat less probable. The presence of occult blood in the stool is of considerable significance as indicating that the gastro-intestinal tract is not normal and that cancer may very well be present. If either or both of these findings are present, that is, the absence of free hydrochloric acid in the gastric contents and the presence of occult blood in the stool, then certainly the

physician is not only justified but ethically compelled to urge strongly the need for further examination. The absence of either of these findings should indicate some conservatism of treatment but the persistence of symptoms for more than a monh after the institution of medical treatment should also be an indication for further examination. The most important part of this further examination is a thorough and competent roentgenoscopic and roentgenographic examination of the stomach.

By selecting cases in this manner, the *x*-ray examination of the majority of patients with carcinoma of the stomach may become feasible. The possibilities of very early diagnosis by this method are not well known. So few cases are referred for roentgen examination at an early stage that it is difficult to determine how accurate the method would be under those conditions. The author has had striking evidence, however, in a number of cases which indicate the remarkable possibilities which are present. In some cases, for example, it is possible to demonstrate by *x*-ray examination a carcinoma which is so small that the surgeon cannot palpate it after the abdomen has been opened. I have seen one case in which the pathologist was doubtful as to the presence of any lesion on gross examination of the portion of the stomach removed at operation, although the lesion was perfectly obvious on roentgenoscopic and roentgenographic examination. It is possible, in many cases, by the careful use of both the roentgenoscope and films, to distinguish between benign and malignant gastric tumors. I have been able, in two cases, to demonstrate both types, independent of each other, in the same stomach. The demonstration of a benign papilloma of the stomach can frequently be made and thus a possible precursor of gastric cancer can be removed. The distinction between benign and malignant gastric ulcers can also be made by the roentgenological method, but with greater difficulty. It must be borne in mind that benign ulcers, adhesions, spasm and other functional conditions, and pressure from extra-gastric lesions may simulate carcinoma and must be ruled out.

The difficulty of the *x*-ray examination of the stomach cannot be over-emphasized. It is no doubt the most exacting type of roentgen examination to make and perhaps is one of the most difficult diagnostic procedures in medicine. The importance of the experience and competence of the examiner can therefore not be overestimated. While in the hands of a Carman the diagnoses may be 95 per cent correct and 5 per cent in error, in the hands of a tyro the figures may very well be reversed. The possibility of overlooking a small carcinoma of the stomach is so great and the consequences so serious that the greatest care must be exercised in making the examination. In addition to the competence of the examiner, an adequate equipment is necessary in order that good roentgenograms may be made.

It is not within the province of this paper to consider the technic of the examination and the diagnostic criteria in detail. In brief it may be said that the best method consists of a combination of roentgenoscopic and roentgenographic examinations. For the inexperienced examiner it is especially important that a large series of good films of the stomach in several positions be made as small lesions may be easily overlooked on roentgenoscopy alone. In determining the presence of a small carcinoma, the absence of peristalsis in a portion of the stomach wall, rigidity to manipulation, and loss of the usual rounded contour are probably the most important signs. The presence of a small filling defect almost resembling a finger print on the film is also a frequent and important sign. In general the findings may be the same as in advanced carcinoma except that they are smaller and more difficult to observe. It is well to remember also that repeated roentgen examination is a justifiable and necessary procedure. A small lesion overlooked at one examination may be seen the very next day when the examination is repeated. If a few weeks or a month is allowed to intervene between examinations, the diagnosis of a doubtful case may become certain. Too often a negative diagnosis is taken as final in spite of the character of symptoms which should clearly indicate the necessity for repeating the procedure. By considering carefully all the clinical and roentgen evidence, by seeing and examining the patient repeatedly, the diagnosis of carcinoma of the stomach may be made at a much earlier stage than is done at present.

SUMMARY

Carcinoma of the stomach is the most frequent cause of cancer mortality and is one of the common causes of death in the later decades of life.

The importance of early diagnosis lies in the fact that small lesions are frequently curable by radical surgery.

The average physician fails to recognize these cases until long after they have become inoperable.

Every patient past the age of forty with gastric symptoms should have a thorough examination including especially gastric analysis, stool examination and a competent *x*-ray examination of the stomach.

The latter, in experienced hands, is one of the most accurate procedures in medicine. The early diagnosis and the cure of carcinoma of the stomach would be greatly facilitated if more patients with gastric complaints were thoroughly examined by the roentgen method.

FUNERAL DIRECTORS COÖPERATE IN HEALTH WORK

The following excerpts are taken from an address by Dr. H. Jackson Davis, epidemiologist, on "How Funeral Directors Can Help in the Control of Communicable Diseases," delivered before the annual convention of the New York State Funeral Directors' Association. The excerpts were originally printed in Health News, August 25, 1930.

In his capacity as a sanitarian, it is the duty of the funeral director to protect his associates and the public from the dangers of communicable diseases. The possibility that the presence of a communicable disease may not have been recognized presents the greatest danger for the funeral director and his assistants. This is strikingly shown in the following instances:

A few years ago, in a neighboring Canadian Province, approximately forty cases of unusually severe smallpox and twenty-one deaths were directly traced to a case and death from hemorrhagic smallpox which was not diagnosed as such. A considerable number of these cases were exposed only at the time that they attended the funeral of the initial case. This epidemic would have been prevented if those in contact with the patient, before or after his death, had been recently vaccinated. As a matter of fact, in this outbreak, more than 50,000 people were vaccinated within a space of ten days and the epidemic was checked.

The second instance involved an undertaker's assistant who had never been vaccinated. A man, 74 years of age, left Illinois in the spring of 1924, to visit his brother who resided in a small isolated village in New Jersey. He was taken ill 13 days after his departure for the east and died a week later, death being ascribed to kidney disease and heart failure. The body was embalmed and shipped back west. The undertaker's assistant, a man 48 years of age, who helped embalm this body, was taken ill within two weeks, with what proved to be a severe case of smallpox from which he eventually recovered. He had not been away for several months and insisted that he had seen no one whom he suspected might have had smallpox. He distinctly recalled, however, having seen an eruption identical with his own on the corpse he had helped embalm. About the time that the undertaker's assistant became ill, another severe case of smallpox developed in a woman living in the household in which the Illinois resident had died.

It was later learned that just before going east, the man who died had been exposed to a case of smallpox in the house in which he boarded. Hence, the presumption seemed warranted that he had died in the early stages of hemorrhagic smallpox, undiagnosed as such.

Vaccination is a safe and harmless preventive of smallpox. Less than half of one per cent of all persons having smallpox in upstate New York during the past five years gave any history of having claimed to have been successfully vaccinated within seven years preceding the attack. Funeral directors should not only apply scientific principles of disinfection and cleansing in their work but should see that every individual who is associated with the preparation of bodies for burial is vaccinated every three years.

EARLY DIAGNOSIS AND TREATMENT OF MALIGNANT CONDITIONS OF THE MOUTH AND LIPS*

FREDERICK A. FIGI, M.D.
Rochester, Minnesota

MALIGNANT tumors of the mouth and lips, because of the possibility of their being recognized early, because of their accessibility, and because of the ease with which the lymphatic drainage of these areas can be blocked, offer a good prognosis in a high percentage of cases if proper treatment is instituted promptly. The patient usually is aware of the presence of trouble in this region earlier than in almost any other portion of the body. Indifference due to lack of appreciation of the possible seriousness of the condition, however, often leads him to delay seeking medical advice. At an early stage the lesion looks no different to him than inflammatory ulcers, fissures or traumatic areas that have appeared in the same region many times previously and that have healed spontaneously. The persistence of the lesion, or its increase in size, ultimately arouses his suspicion of its possible seriousness. Then, if he is wise, he seeks the advice of his family physician. If he is not wise, he visits a cancer quack. Various educational measures have been carried out in recent years by different medical organizations. These measures include the institution of "Cancer Week" and the delivering of lectures on public health. They have resulted in fewer patients with questionable conditions of the lip and mouth visiting the charlatan, whereas increasing numbers are coming to the physician when the growth is still in an early stage.

The treatment most commonly used by the quack consists of applications of an escharotic, usually an arsenic paste. If the destruction is carried out sufficiently widely this often cures the local growth. Otherwise, as with any incomplete treatment, increased activity results. As a rule, an appreciable portion of the lip is lost, with the production of more or less deformity. This, however, is of minor consideration, in view of the seriousness of the condition. One of the principal objections to this type of treatment is that no attempt is made to determine the nature of the growth. The lesion is treated in the same way, whether it is inflammatory, or a benign or malignant neoplasm, but the patient is always given the impression that it is malignant. Of greater importance, however, is the fact that the patient receives a false sense of security. As a rule, consideration is not given the lymphatics which drain the area. Therefore, later, when an enlarged node appears in the submental or the submaxillary region, as occurs in from 20 to 30 per cent of cases even if local recurrence is absent, the patient does not appreciate the seriousness of the situation and often allows the condition to progress to an inoperable stage.

On the other hand, physicians also are capable of making errors. Even though the patient with such a lesion consults his physician first, it is by no means a certainty that he will receive treatment which will offer him the greatest assurance of cure. Many times, on account of the insignificant appearance of the lesion, silver nitrate or other mild caustic is applied, or it is decided to try radium or roentgen rays. If the lesion is already malignant, this attempt to determine what these different agents will accomplish is likely to deprive the patient of his best chance to get well. Such treatment is usually incomplete and stimulation of the growth, with increased possibility of metastasis, often results. Every precancerous lesion should be given the same consideration as lesions that are malignant, until their benign character is definitely established. In an adult a high proportion of chronic sores of the mouth or lip are malignant, and it is inexcusable to treat such a condition without first making every effort to establish a diagnosis. As a matter of fact, the possibility of malignant change in such lesions is not limited to adults alone. Many times epitheliomas of the lower lip are encountered in persons in their early twenties or even in their teens. At The Mayo Clinic an epithelioma of the lower lip was excised recently from a boy aged thirteen years (Fig. 1). If the area on the lip has a slightly indurated border, the diagnosis may be evident on clinical examination alone, to one of sufficiently wide

*From the Section on Laryngology, Oral and Plastic Surgery, The Mayo Clinic, Rochester, Minnesota. Read before the Minnesota State Medical Association, Duluth, July 14 to 16, 1930.

experience. In approximately half of the cases, however, a microscopic examination only will permit of an accurate diagnosis. This is particularly true of lesions which have their origin in areas of leukoplakia, especially of syphilitic type (Figs. 2, 3 and 4), chronic thrush, recurring chronic fissures, and other ulcers of the mouth and lip which are inflammatory only. Such lesions can be excised readily under local anesthesia, without appreciable deformity, and following microscopic study treatment of the lymphatics can be carried out, if it is indicated. If the growth is so large or is so situated as to render complete excision inadvisable, there should be no hesitancy in removing a portion for biopsy. Lesions that have been treated previously present the greatest difficulty from a diagnostic standpoint. Biopsy is frequently unsatisfactory in these cases, because the marked inflammatory reaction renders the results of microscopic study uncertain. Many times observation over a period of several weeks, or even of months, may be necessary in order to establish a diagnosis.

Little is to be gained by reviewing the controversy existing between surgeons and radiologists as to the most effective method of treating carcinoma of the mouth and lip. The comparative prognosis with operation and with irradiation is the criterion on which choice of treatment should hinge. The negligible difference in the cosmetic result and the slight operative risk associated with the surgical treatment of such lesions are of minor consideration, although to the lay mind they are often outstanding. It is now generally conceded that a combination of operative procedures and irradiation offers the best prognosis in the majority of cases.

The type of tumor and the rapidity of its growth are most important considerations in determining the treatment advisable in a given case. Broders' method of grading carcinomas according to their activity as evidenced by cellular differentiation and formation of keratin has been of inestimable value from the standpoint of prognosis and treatment. This grading by microscopic examination has, with few exceptions, corresponded strikingly with the clinical course of the disease. The slow-growing, mildly malignant lesions are designated as of grade 1, and the successively more active growths as of grade 2, 3, and 4, respectively. In lesions graded 1 the local growth is, as a rule, readily controlled and extension in the lymphatics is not likely to occur. Tumors graded 4 present rapid local growth, matastasize widely, and are prone to recur

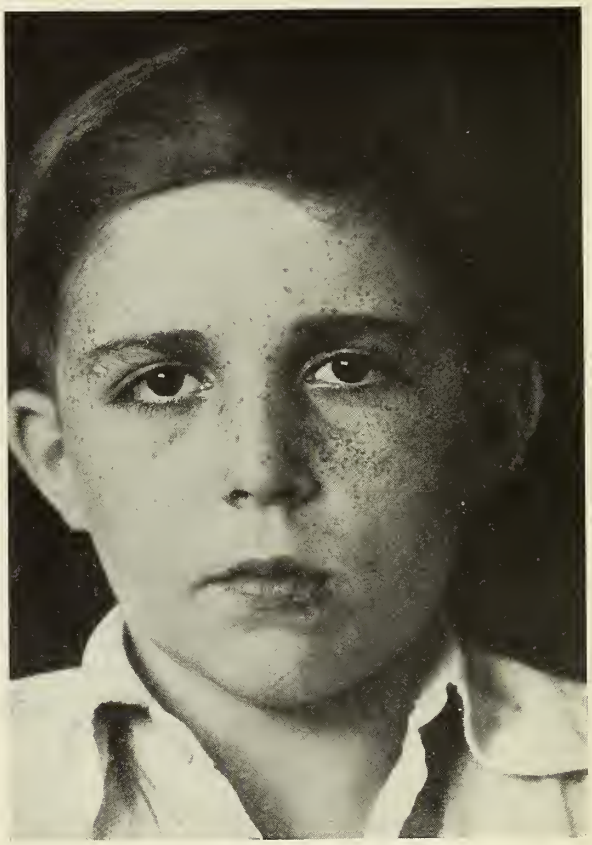

Fig. 1. Boy aged 13 years with squamous cell epithelioma of lower lip.

promptly following removal. Lesions of grade 1, 2, or 3, if they are surgical, should be excised or destroyed with the actual cautery or diathermy, and the regional lymph nodes should be removed subsequently. With neoplasms of grade 4, intensive irradiation should be directed against both the local lesion and the regional lymphatics. The primary growth is also treated surgically at times, but irradiation constitutes the major part of the treatment.

In the clinic, epitheliomas of the lip are removed surgically unless there is definite contra-indication to operation. The risk associated with the removal of such growths, together with the regional lymphatics, has been found to be so slight that comparatively few contra-indications exist. Even though the lesion is extensive, if it is of a low grade of malignancy, and if there is no attachment to the mandible, immediate

plastic reconstruction of the lip is permissible. After removal of the entire lower lip, sufficient tissue can be brought in from the cheeks to restore the lost parts satisfactorily, both as regards

Fig. 2. Squamous cell epithelioma of lip.

function and cosmetic appearance. If the growth is active and involves the cheeks, or if it is attached to the mandible, wide excision with the cautery knife, or destruction by surgical diathermy, leaving the wound wide open, is advisable. Thorough cauterization of the surface of the mandible over the area of attachment is necessary in such cases. Plastic reconstruction of the lip is deferred until the patient has been free from evidence of trouble for at least nine months to a year, depending on the extent and activity of the growth. It may then be effected by means of a lined flap from the forehead, a triangular flap from the upper lip, or a tube flap from the thorax. Removal of the submental and submaxillary lymph nodes on either side, as well as of the upper jugular group of nodes on the side of the involvement, is carried out in all surgical lesions of the lip. This is usually done at an operation subsequent to the one at which the primary growth is removed. If excision by cautery has been necessary, dissection of the nodes must, as a rule, be deferred for about three weeks. However, this may be done before the operation on the lip. If involvement of the nodes is obvious on clinical examination, the operation on the nodes usually precedes treatment of the primary growth. In all cases in which involvement of the nodes is demonstrable at operation subsequently, intensive treatment by roentgen rays or radium is given. If the patient's age or general condition contra-indicates surgical operation, the lesion of the lip, and the lymphatic structures, are treated with irradiation alone. As a rule, dissection of nodes is not carried out if patients are aged more than seventy years, unless the growth is distinctly active and the patient's general condition is unusually good, since there is less likelihood of extension by the lymphatics if patients are advanced in years. Lesions that have received treatment with irradiation previously must be treated more widely, and the possibility of recurrence is greatly increased.

The treatment of carcinoma involving the insides of the cheeks is much the same as that of carcinoma of the lips. Small, superficial epitheliomas in this region may be excised with the cautery knife. As a rule, however, these lesions, as well as the extensive ones, are more readily and satisfactorily treated with surgical diathermy. If the tumor is perforating the cheek, the full thickness of the cheek should be excised with the cautery knife. The defect should be left wide open and should be closed later by means of a plastic procedure. Radium is often used as an adjunct in these cases; radon points are inserted into the wound at the time of the operation, or the plaque or tubes are used later. If metastasis from carcinoma of the cheek takes place it invariably appears on the same side as that of the lesion unless the growth is extremely active or has been treated previously with irradiation. Dissection of the nodes as a rule is deferred until about three weeks after the operation in the mouth, although if there has been clinical evidence of involvement it may be done the following day providing there is not too much local reaction.

The malignant tumors of the jaws consist of epitheliomas, sarcomas of different types, and adamantinomas. Epitheliomas are by far the most common. A large percentage of these are of low grade or moderate activity. They may

vary from the inactive lesions which develop in areas of papillary leukoplakia to fulminating, sarcoma-like neoplasms, graded 4. The clinical appearance presented by these neoplasms of varying activity is distinctive, although this difference is difficult to describe accurately; in general, the softer, more friable and more vascular the lesion, the higher its grade of malignancy.

Fig. 3. Epithelioma developing in area of syphilitic leukoplakia inside right angle of mouth. Area of leukoplakia posterior to angle of mouth on opposite cheek may be noted.

Epitheliomas of the jaws are better treated by surgical diathermy or the actual cautery than by resection. In the very active growths, intensive irradiation is used in addition to surgical measures, and reliance is placed chiefly on this. Diathermy in these cases is used chiefly to coagulate the tumor and its attachment, thus producing a dry, sterile bed into which radon points may be inserted. In low-grade epitheliomas, surgical measures are relied on almost entirely. The regional lymph nodes in these cases present much the same problems as in cases of epithelioma of the lip and cheek, although, if the lesion is confined to the alveolar process alone, metastasis is much less likely to occur than when the adjacent soft tissues are involved.

Most of the malignant tumors of the body of the tongue are epitheliomas. They are, as a rule, easily recognized clinically. Because of the danger of early metastasis from such lesions, it is especially important that a definite diagnosis be established and treatment be instituted promptly. Surgical lesions of the tongue may be excised sharply or with some form of cautery knife. Often radium seeds are inserted into the open wound prior to suturing. Closure of the wound following excision, either by the knife or with the cutting cautery, usually is followed by primary healing. If radium points are inserted, the wound frequently will open later. When the growth on the tongue is extensive or the floor of the mouth is involved, surgical diathermy is preferable to excision. Following surgical diathermy there is increased danger of secondary hemorrhage on separation of the slough. As soon as the wound in the tongue permits, a bilateral dissection of the submental and submaxillary nodes with a cervical block on the side of the involvement is done if the patient's general condition warrants. If the patient is not a good surgical risk, more conservative dissection of the nodes is carried out. All patients with carcinoma of the tongue receive intensive irradiation of the regional lymphatic structures, regardless of the type of treatment used on the local lesion.

The results following early treatment of carcinoma of the lip in the clinic are extremely satisfactory in the majority of cases. More than 90 per cent of the patients are well after five to eight years in the cases of such lesions in which the lymph nodes were removed along with the lesion of the lip before there was demonstrable

evidence of involvement. If the nodes are involved at the time of removal the chance of cure is markedly reduced, even if more extensive resection of lymph nodes is carried out. Studies

Fig. 4. Squamous cell epithelioma of tongue developing on syphilitic leukoplakia.

made by Broders in 362 cases of carcinoma of the mouth and throat in which operation was done in the clinic between 1904 and 1915 disclosed that more than 65 per cent of patients without metastasis from malignant tumors of the mouth obtained good results. Of patients without metastasis from carcinoma of the tongue 50 per cent were well. If treatment of carcinoma of the mouth was delayed until after the lymph nodes became involved, the prognosis was much less satisfactory. In recent years irradiation to supplement surgical measures has been used as a routine. Such treatment should yield an increased number of cures, although statistical studies of results have not yet been completed.

CONCLUSIONS

1. Treatment should never be instituted in any chronic lesion of the mouth or lip until a diagnosis has been established. If this procedure were carried out as a routine, the prognosis in malignant tumors of this region would be greatly improved.

2. The treatment advisable in a given case of malignant growth of the mouth or lip is dependent on the age of the patient and the extent and activity of the growth. Operation is more effective in lesions of low grade and in those of moderate activity, whereas irradiation is preferable in highly malignant tumors. Surgical measures, supplemented by irradiation, offer the best prognosis in the majority of cases.

THE EARLY DIAGNOSIS OF CANCER OF THE UTERUS*

W. A. Coventry, M.D., and R. J. Moe, M.D.
Duluth

CARCINOMA of the uterus must, clinically, be divided into that involving: (1) the cervix; and (2) the body of the uterus.

Carcinoma of the body of the uterus has a far more favorable prognosis, both in its early and late stages, than that of the cervix. By this I mean that a late diagnosis of cancer of the body of the uterus is not so disastrous as a late diagnosis of cancer of the cervix.

As a matter of fact, the infrequency of cancer of the body of the uterus makes it more easily overlooked, and although extension of the cancer, either direct or by metastases, is slow, one must ever be on his guard in cases of menorrhagia or metrorrhagia occurring after thirty-five years of age. The first thought should be of cancer, especially when no other demonstrable tumors can be felt on bimanual examination. The proper procedure in these cases is to do a diagnostic curettage and submit the curettings to microscopic examination. I fear that at the present time this method of arriving at a diagnosis is not used as frequently as it should be, and really it affords the only safe way by which a diagnosis can be made.

The treatment in these cases lies between: (1) a complete hysterectomy, which can be done with greater prospect of cure than when the case is one of carcinoma of the cervix; and (2) the use of radium. Both methods may be used. Fortunately the prognosis is good.

On the other hand, the other type of carcinoma of the uterus, that is, carcinoma of the cervix, exacts, according to statistics, a toll of 10,000 deaths every year. This is a story more sad than that of cancer of the breast.

Fluhmann reports a large series of cases of carcinoma of the cervix in which, at the time the patients presented themselves for examination, 71 per cent were far advanced and 28 per cent showed limitation to the cervix, leaving a small margin of from 1 to 2 per cent in whom early cancer of the cervix was found. Other writers have reported similar statistics showing that over 95 per cent of all patients who presented themselves with cancer of the cervix were far beyond the so-called stage of early diagnosis and afforded a very poor prognosis for even a three to five year cure.

Clark and Ferguson show that of all patients who came under observation within six months of the first symptom manifest to the patient, 60 per cent were inoperable and that one in seven had a chance for a five year cure, while, if they had presented themselves for examination some time after the six months period in which the symptoms first developed, only one in twenty-six had a chance for a five year cure. Is it any wonder that we should exert ourselves to search for and attempt to recognize early cancer of the cervix, or seek for methods which will prevent the formation of this dreaded disease.

Unfortunately it is impossible to tell, from the clinical or microscopic picture, how long a cancer has been present. But more can be told as to the prognosis.

In Schmitz's clinical classification the cases are divided into four groups:

1. A simple localized growth or nodule with no infiltration.

2. Beginning infiltration within the confines of the cervix.

3. Invasion into the parametrium, easily determined by rectal examination.

4. The presence of necrosis, infiltration, sepsis, etc.

With each successive stage the prognosis becomes more grave. With this clinical classification must be coupled Broders' classification of the microscopic picture in which he has shown that the more a neoplastic cell approaches the normal cell, the less malignant the tumor, and, conversely, the more malignant the tumor, the more undifferentiated or more embryonic the new cells. It seems to me that Schmitz's classification as well as Broders' must be kept in mind in estimating the prognosis in these cases of carcinoma. At best the usual case of carcinoma of the cervix has developed beyond the favorable stage.

*From The Duluth Clinic, Duluth, Minnesota. Read before the Annual Meeting of the Minnesota State Medical Association, Duluth, July 14, 1930.

In view of these statistics does it not behoove us to consider what can be done to prevent carcinoma of the cervix?

The cause of carcinoma, of course, is not definitely known, but clinical experience has shown that certain factors, namely irritation and infection, have an etiological bearing.

Pemberton and Smith have shown that cancer of the cervix is preceded by pregnancy in 90 per cent of the cases. Pregnancy leaves as its aftermath cervical laceration or infection, or both. Naturally, then, our attention should be directed to these conditions.

The subjective symptoms consist of vaginal discharge and uterine bleeding in some form.

Vaginal discharge in a very large percentage of cases is due to inflammation or infection of the cervix. The few exceptions are probably those cases of infection with Trichomonas vaginalis. Clark and Ferguson report that 25 per cent of their cases presented themselves with discharge in some form.

Bleeding may be simple spotting, irregular or profuse bleeding, or bleeding upon irritation. Clark and Ferguson have shown in their series that 75 per cent of the cases presented themselves with hemorrhage in some form. These two salient facts, vaginal discharge and bleeding, must not be lost sight of.

Certain points in diagnosis should be emphasized:

1. A digital as well as a speculum vaginal examination should be made in all cases of bleeding that are irregular in any form. A speculum examination should be made in all cases of vaginal discharge and the cause of the discharge determined.

2. The general appearance of the cervix must be determined and certain facts ascertained: is it lacerated, does it bleed on manipulation, is it soft when touched with the forceps, are there any hard, isolated nodules, is it papular?

There features are not necessarily apparent in the vaginal portion of the cervix, but also must be searched for in the cervical canal itself. One must always bear in mind that an early diagnosis of cancer of the cervix is very difficult to make clinically.

A positive diagnosis can only be made by doing a biopsy in all suspicious cases. The patient need not necessarily be sent to a hospital for a biopsy. It can be done in the office. It is not painful. The fear that one may have that if it is a cancer, it may be spread by using a knife, can be allayed by the fact that one can cauterize the base of the cut surface and seal the lymphatics.

To my mind much can be done by cleaning up these eroded cervices by using the nasal cautery, burning down the erosions and ectopions and establishing a healthy, non-infected cervix. This is a simple office procedure and does cure these cases. In my opinion one is grossly negligent who ignores this responsibility. This is especially true in the postpartum stage, but should be done in all cases and the age of the patient should not have any bearing as regards this prophylactic measure.

Pemberton and Smith report that in a series of 3,814 trachelorrhaphies, 740 amputations if the cervix and 1,408 cauterizations of the cervix (a total of 5,962 cases seen in the Free Hospital for Women), only five cases were known to have developed cancer and these were in the trachelorrhaphy group. It seems to me this speaks volumes for the efficiency of cauterization and the cleaning up of infected cervices.

In those cases of carcinoma of the cervix discovered early, radium or hysterectomy, or both, offer a very favorable prognosis. As to the relative merits of hysterectomy or radium treatment, I will leave that to your own judgment.

SUMMARY

In all cases of irregular bleeding coming from the body of the uterus one must bear in mind the possibility of cancer and a diagnostic curettage should be done.

Forty per cent of all cancers in women are in the uterus.

Ninety-five per cent of all cancers of the cervix that are demonstrable at first examination at the office offer a very unfavorable prognosis for cure. Therefore, one should make every possible attempt to arrive at as early a diagnosis of cancer of the cervix as possible, and every measure of prophylaxis against the development of cancer should be instituted.

Free use of the nasal cautery, the repair of lacerations, and amputation of the cervix as indicated, give us our best hope to date in the prevention of cancer of the cervix.

Every vaginal discharge or irregular bleeding

should be thoroughly investigated to determine its cause and that cause removed.

Only by very rigid methods of examination can we hope to obtain any measure of relief in the prevention of cancer of the uterus.

The slogan for all lesions of the uterus should be:

"Early diagnosis — thorough investigation — immediate treatment."

CARE OF VETERANS

The following resolutions offered by the Board of Trustees of the American Medical Association were adopted by the House of Delegates at the annual meeting in Detroit in June and a copy sent immediately to the President of the United States:

Resolved, That, in the opinion of the House of Delegates of the American Medical Association, legislation to extend in point of time the presumption of service origin of diseases and injuries from which veterans are suffering, to establish arbitrarily the service origin of such diseases and injuries, and to extend greatly the category of such diseases, is without sound basis in the science and art of medicine;

Resolved, That the provisions of such legislation to the effect that lay evidence as to the nature and extent of diseases and injuries is to be given added consideration will give to such evidence weight to which it is in no way entitled and cause pressure on the Veterans' Bureau to allow claims for compensation without adequate medical support;

Resolved, That legislation recently enacted providing for the enlargement of the hospital facilities at the command of the Veterans' Bureau for the care of veterans, rich and poor, who desire hospitalization and treatment for diseases and injuries that admittedly have no relation whatever to military service is unsound and communistic in character and the pending proposal to allow such veterans as are of financially limited means bonuses and money to add to their own comforts while they are in the hospital and to help support their families during that period and for limited periods thereafter is calculated to induce patients to seek hospital care through the Veterans' Bureau when such patients should be better and more economically treated as ambulant patients or treated in their own homes;

Resolved, That the duty of providing medical and hospital care and financial relief for indigent citizens of any state, when disabled by diseases and injuries that did not originate in the line of military duty, is a function not of the federal government, but of the governments of the several states and should be discharged through state agencies, including permanently established state, county, municipal and private hospitals; and

Resolved, Further, that a copy of these resolutions be sent to the President of the United States.

THE DIAGNOSIS OF MALIGNANT CONDITIONS OF THE COLON*

Fred W. Rankin, M.D.
Rochester, Minnesota

TO set down in sequence a chain of symptoms produced by carcinoma of the large bowel is difficult, if not impossible, particulary if one limits oneself to the earlier manifestations of the disease. The reasons for this are that the colon is at least a bifunctional organ and the symptoms of malignant neoplasms vary according to (1) situation, (2) pathologic type, and (3) the presence or absence of complications, such as metastasis, ulceration, or perforation.

Functionally, the right half of the large bowel is the absorptive portion, and the left half is concerned mostly with storage. Fluids are extracted from the intestinal content as far around as the middle of the transverse colon, and the hardened, dry, formed feces are deposited beyond this portion of the bowel to be expelled periodically without having many products extracted from them. The proximal half of the large bowel develops, with the small bowel, from that portion of the primary alimentary canal which is called the midgut, and functionally it corresponds with the small bowel. The distal segment is developed from the hindgut.

In general, it may be said that approximately 25 per cent of all the carcinomas of the colon occur in the sigmoid flexure, and about 15 to 18 per cent occur in the cecum and ascending colon. Next in order comes the mobile transverse segment, with its two fixed points, the hepatic and splenic flexures.

These anatomic divisions are important from the standpoint of symptoms only, because obstruction may occur at the angulations. For practical purposes, as related to the syndrome of symptoms, one may consider the right half of the colon around to the middle of the transverse segment one organ, and its fellow of the opposite side a different organ, pathologically, clinically, functionally and developmentally. The differences in symptoms of the two segments are mainly the differences in physiologic evidences of pathologic changes as demonstrated by growths of the right side, and intestinal obstruction, chronic, subacute or acute, as evidenced by lesions of the left half of the colon. Pathologically, the two halves of the colon show marked differences, although the majority of the growths are of the adenocarcinomatous variety.

In the right half of the colon one finds large, flat, ulcerating growths which frequently are covered with stubby protuberances like granulation tissue, and over which often is spread a dirty, necrotic exudate. These growths usually lie on the lateral wall of the bowel, and in this segment of the colon do not tend to produce obstruction because of (1) the liquid nature of the fecal current in this situation, (2) the lack of tendency of the growth to encircle the bowel, which has a greater lumen than elsewhere in its course, and (3) the likelihood of the growth to go on to penetration, perforation or abscess formation.

In the main, it may be said that cases of malignant growths of the right half of the colon may be classified according to symptoms under three headings: (1) cases in which the diagnosis is dyspepsia, mild in character and with few localizing symptoms, or in which the diagnostic term is a synonym of the vague term intestinal indigestion or chronic appendicitis; it must be said that cases of this kind are insidious of onset, slow of progress and frequently advance to tumefaction or some complication before they are recognized; (2) cases in which weakness and loss of weight, loss of strength, and anemia are the outstanding symptoms, and (3) cases in which there is the discovery, accidental or otherwise, of a tumor in the right iliac fossa, hitherto unsuspected.

In the first group are a relatively large number of carcinomas of the right half of the colon. Because of this I would call attention to the fact that carcinomas of the whole colon, in their earliest stages, in probably 95 per cent of the cases, have very few pathognomonic symptoms and usually are evidenced by change of intestinal habit or by intestinal irregularity,

*From the Division of Surgery, The Mayo Clinic, Rochester, Minnesota. Read before the Minnesota State Medical Association, Duluth, July 14 to 16, 1930.

such as mucous diarrhea, or alternating periods of constipation and diarrhea. The obvious corollary to this is that one should have a thorough investigation of the gastro-intestinal tract if change of intestinal habit or irregularity persists over a period of, for example, one week to one month. I am confident that this would obviate many of the disasters which one finds among patients who present themselves in the late stages of the disease, and in which formation of abscesses, penetration, perforation, or distant metastasis has taken place, precluding surgical intervention or, at least, limiting it to palliative measures. Pain and local tenderness over the cecal area, simulating subacute or chronic appendicitis, and without a tendency to disappear entirely, should call attention to the necessity of gastro-intestinal examination, because occasionally these are among the early symptoms to be found.

Fig. 1. Filling defect in proximal part of descending colon near splenic flexure. Carcinoma (surgically substantiated).

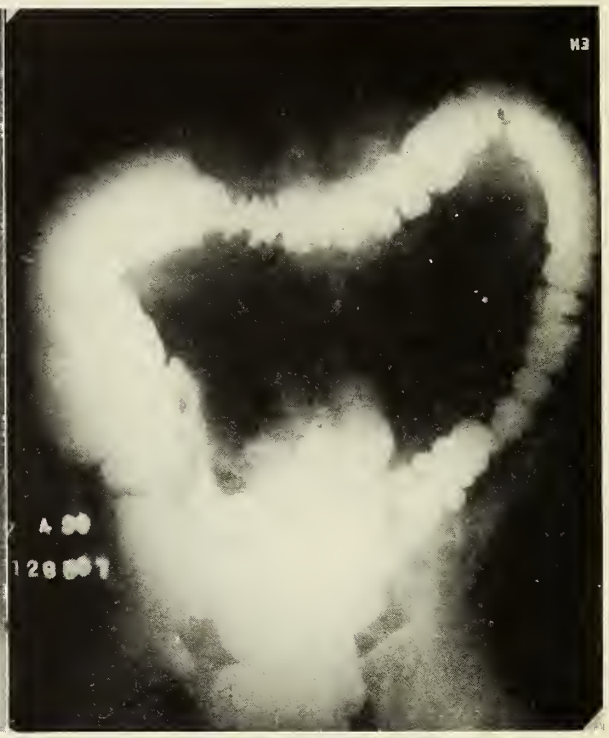

Fig. 2. Polypoid filling defect in distal part of descending colon. Adenocarcinomatous polyp (surgically substantiated).

In the second group, namely, that characterized by anemia, is one element which is outstanding as a symptom of carcinoma of the right half of the colon; that is, profound anemia, with concomitant change in the entire blood picture. This anemia is always unassociated with visible loss of blood and frequently may be called attention to by an attack of unexplained weakness or inability to carry on work; or it may be noted in the course of a general examination and may be without apparent cause. The exact explanation of this type of anemia is not clear, but it seems relatively certain that it is due to some perverted function of the mucous membrane which impairs it to such an extent that absorption of toxins results. The work of Whipple and Smith, Koons, and others, has called attention to this classical and almost pathognomonic picture. Sometimes the concentration of hemoglobin becomes as low as 25 per cent, and not infrequently I have been called on to attack surgical growths in the presence of a concentration of hemoglobin of 30 or 35 per cent. Characteristic of this also is the fact that these patients, with this blood picture, stand resection of the right half of the colon relatively favorably, indeed much more so than would a patient with the corresponding blood picture due to carcinoma of the stomach. So frequently does one find pro-

found anemia associated with growths of the right side of the colon that I am strongly of the opinion that no patients should receive a diagnosis of pernicious anemia until thorough examination of the entire colon has precluded the possibility of a malignant growth in the right half. It is an axiom that pernicious anemia should always be distinguished from anemia caused by carcinoma of the stomach, but I am confident, from my own experience, that there is far less likelihood of it being confused with gastric malignant growths than with colonic carcinoma.

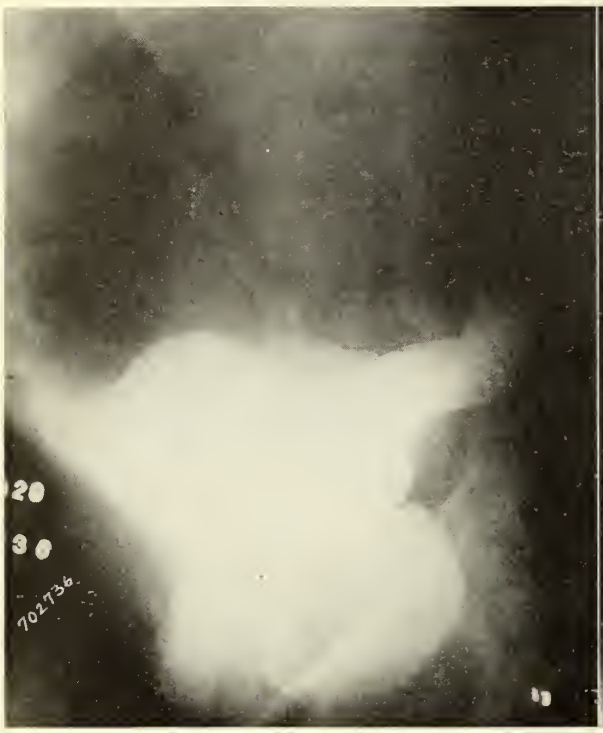

Fig. 3. Obstructing carcinoma of descending colon at level of the left iliac crest (surgically substantiated).

Fig. 4. Extensive filling defect in the cecum. Carcinoma (surgically substantiated).

Symptoms of malignant growths of the left half of the colon revolve around a syndrome of obstruction that is influenced by the scirrhous nature of the growths which have a tendency to encircle the bowel and to produce slow and progressive stenosis. Borborygmus and visual peristaltic movements are usually noted by most observers as being among the early symptoms. The borborygmus, associated with increased flatulence, may be accounted for by change in the intestinal contact, or it may be due to degeneration of the tumor or to obstructive changes which accompany stenosis. Visualization of peristaltic movement is possible only in lean persons or in persons in whom the contraction of the lumen of the bowel produces such obstruction to the fecal current and peristaltic wave as to produce proximal dilatation with increased stenosis. The effort of the bowel to force its content through the intestinal lumen may be observed more clearly, and occasionally a definite point of stoppage may be noted. In addition, the character of the fecal content of the left side is different; it is formed and hardened. To detect tumefaction in the left half of the colon is much more usual than to detect it in the right half, probably because of its greater accessibility, but more likely because of its obstructive nature which dams back the content of the bowel and produces dilatation and obstruction. Progressive constipation occurs in a high proportion of these cases, probably in between 25 and 40 per cent, and should call attention to the presence of some mechanical stenosis in the majority of cases before roentgenologic evidence is sought. It is difficult, however, to define in any person exactly what constipation is. The direct question as to the number of stools each day may or may not elicit this information accurately, for a patient

is frequently inclined to consider his bowel movements normal whereas he may have gone to stool many times a day and, in fact, pays little attention to the early intestinal irregularity, be it of the variety of diarrhea or of constipation. However, again let me emphasize that the change in intestinal habit is the most important early symptom of carcinoma anywhere of the large bowel. Chronic diarrhea in an elderly person frequently proves to be due to a malignant growth. If the growth is on the left, Moynihan's axiom is strikingly true: "In left colonic growths, constipation is the rule, while in right colonic growths, constipation is rare." The aphorism of Morison in this regard is as follows: "Increasing constipation of recent origin in an elderly person, only overcome by purgatives, suggests malignant disease of the colon." This obstruction may be either of the acute or chronic variety. If it is in the former division, it may be due to volvulus, intussusception, plugging of the lumen of the bowel by a foreign body or to swelling due to an inflammatory process superimposed on the malignant condition. The chronic form of obstruction occurs in the vast majority of cases of carcinoma of the colon, due to direct encroachment on the lumen of the bowel and dependent on the pathologic type and rapidity of the growth. In the splenic flexure, obstruction of a chronic or subacute variety is present in 100 per cent of the cases. Fortunately, carcinomas of the splenic flexure metastasize slowly because of the scarcity of local lymphatic drainage, and although they are frequently complicated by perforation and abscess, if one can attack them by the primary operation, the ultimate prognosis is satisfactory. Obstruction of the acute variety occurs in about 5 per cent of the cases and represents a most grave condition, in that acute intestinal obstruction is superimposed on an already fatal condition unless it is relieved surgically. This type of intestinal obstruction usually appears out of a clear sky, without premonitory symptoms, and the patient and surgeon are confronted by a grave state.

Fig. 5. Filling defect in distal part of ascending colon near the hepatic flexure. Carcinoma.

Fig. 6. Filling defect in proximal part of the ascending colon above the ileocecal valve. Carcinoma (surgically substantiated).

There are two symptoms of carcinoma of the colon which are commonly noted in textbooks, and which I wish to call attention to briefly. They are melena and tenesmus.

Tenesmus is noted in direct ratio of frequency as the growth approaches the rectal sphincter; that is, the lower down the growth, the greater the irregularity of the bowel and the more

Fig. 7. Rather extensive filling defect in proximal part of sigmoid. Carcinoma (surgically substantiated).

severe the straining at stool and tenesmus. It is an untrustworthy symptom of colonic disease and, unless the growth is within reach of the finger, rarely is present at all, save when a subacute or acute variety of intestinal obstruction has developed. Blood in the stool, on the other hand, is the most common symptom of growths in the lower left side of the colon or in the upper part of the rectum. I have little confidence in the presence or absence of occult blood in the stool as a diagnostic measure. Blood in the stool or on the stool is of importance unless its presence is explained away. If it is bright red blood and persists in the stool or on the stool, unquestionably there is a local lesion which is distal to the splenic flexure. Blood in the stool rarely is noted when the growth is in the right half of the colon, even by the more delicate tests for occult blood, and I distinctly wish to minimize its importance diagnostically except as far as it forces persons to have a complete gastro-intestinal examination.

The most important advance in the diagnosis of colonic malignant growths has been the tendency of roentgenologists to improve their technic to such an extent that accuracy of observation and of diagnosis is rapidly approaching the point at which it parallels the splendid information now universally obtainable by roentgenologic examination of the stomach and duodenum.

Characteristic roentgenologic evidence of malignant disease of the large bowel is so accurate that in 102 cases of carcinoma of the large bowel, beyond the sigmoid flexure, examined and proved by exploration at The Mayo Clinic in 1929, an error was made in only three cases. This is a remarkable and most satisfactory record, comparable to the best figures in any series of gastro-intestinal diagnosis. A filling defect, or visualized interference with the integrity of the lumen of the bowel, is so pronounced in the majority of instances in which accurate preparation has been made that experience with the fluoroscope promises to continue this accuracy. Certain nonmalignant lesions of the colon exhibit the same phenomena, but when carcinoma is the etiologic factor, certain pathognomonic features are present, and because of the constancy of the occurrence of this filling defect in a case of malignant disease of the colon and its typical characteristics, the roentgen ray offers the only objective, accurate preoperative diagnostic evidence at the disposal of physicians. The barium clysma, roentgenologically controlled, aided by palpatory manipulation and verified by roentgenography, is the method of choice for accurate detection of the situation of the filling defect and the precise interpretation of its characteristics. Although the defect shows on the roentgenographic films, it is much more desirable to make diagnoses fluoroscopically than to depend on the roentgenogram only. Occasionally, carcinoma causes complete obstruction to the barium enema, but usually one finds definite canalization which may be visualized. The rough, jagged contour of its margin, associated with the firm, knotty consistence of the mass, represent the cardinal differential characteristics. Generally speaking, the chief factor of error in roentgenoscopic diagnosis of colonic lesions is failure on the part of the

roentgenologist to procure adequate exposure of the involved loop of bowel. Strangely enough the sigmoid offers the most difficulty on this account because of its usually inaccessible situation in the bony pelvis and its frequently firm fixation by adhesions, usually of an inflammatory nature. Multiplication of anomalous coils likewise may complicate its visualization. Below the middle of the sigmoid, one should not depend on roentgenologic examination, but proctoscopic evidence is more easily and satisfactorily obtained. The right side of the colon imposes a peculiar difficulty to diagnosis by roentgenoscopy; its comparatively large lumen fails to show the striking degree of narrowing characteristic of the distal portion, and in the cecum particularly an extensive lesion may leave a large, rounded contour at its distal margin which may be misinterpreted as the tip of a normal cecum, in the absence of a definitely palpable tumor. Patience, diligence and care on the part of the examining roentgenologist, together with cooperation of the patient and clinician in securing the best possible preparation of the lumen of the bowel for examination, will aid materially in increasing the diagnostic evidences that are possible to elicit by the roentgenoscopic method.

To epitomize, then, the most important early symptoms of carcinoma in any portion of the colon are change in intestinal habit, as evidenced by irritability, mucous diarrhea, alternating periods of diarrhea and constipation, localized pain and tenderness without a tendency of them to disappear, tumefaction, profound anemia not accompanied by loss of blood, and obstruction of the acute, subacute or chronic variety. Given any of these suggestive phenomena, one should be urged to undergo immediately, at the hands of a competent roentgenologist, complete gastro-intestinal examination, with great assurance that the suspected lesion will be discovered. Let me add that loss of weight, cachexia, dehydration, and desiccation are not symptoms of carcinoma of the colon, but are symptoms of metastasis and impending dissolution, and to wait for such evidences to occur before suspecting a malignant condition and attempting to localize it by some means at hand is little short of being a party to fatal delay.

The prognosis in carcinoma of the large bowel, and the operative mortality, as compared with carcinoma of the stomach, impress one that with earlier diagnosis and more attention to preoperative and postoperative details, an increasingly large number of satisfactory three-year and five-year cures is being obtained.

At The Mayo Clinic it has been the custom recently to attempt to individualize patients with surgical conditions of the large bowel and rectum by segregating them into a group under the joint supervision of clinician and surgeon. This has resulted in the establishment of a routine preoperative preparatory stage which, in the majority of instances, has meant hospitalization, although with increasing experience we have come to recognize a distinct advantage in an ambulatory type of treatment for certain persons. The preoperative measures employed in this group of cases aim at (1) rehabilitation of the patient by decompression of the colon, and increase of the general resistance by introduction of large amounts of fluids, by blood transfusions and by other general hygienic measures; (2) insistence on a diet as free from residue as possible and consisting largely of carbohydrates, and (3) the use of an intraperitoneal vaccine (Figs. 1 to 7).

DISCUSSION

Dr. W. J. Mayo (Rochester): Mr. Chairman: One of my colleagues has said that the first thing to do in examining a patient is to examine the rectum so that you won't forget to do it, and to do it anyway, even if it does soil your hand. With a rubber finger cot or a rubber glove, and a little soap, one can make a clean examination of the rectum.

Patients with carcinoma of the rectum so frequently come to us too late, merely because the physicians in whose hands they have been have not examined the rectum thoroughly. If the patient is placed on his back, with the thighs drawn up, one can introduce the finger and reach high. It is true that one cannot reach up to the sigmoid juncture through the rectum, but one can reach the greater part of the rectum and by combined rectal, vaginal and abdominal manipulation, an excellent diagnosis usually can be made which the *x*-ray can verify.

Again, I would like to say just a word in regard to colostomy. When I first began practice, colostomy had just come in as a common operation, and any patient who had a carcinoma of the rectum had a colostomy made and that was about all. Many a patient with incurable carcinoma of the rectum who would have gone

on with his work for months, if he had not had the colostomy, at once was put into condition in which he no longer could work. It is very rare that a patient with carcinoma of the rectum below the rectosigmoid juncture will suffer from obstruction, and colostomy, except for obstruction, is not usually to be considered. Of course, colostomy as a preliminary to a radical removal of the growth and the rectum is a necessary procedure.

I am reminded of a little story that I read of a small boy who was studying physics. He was shown with books under his arm. He found the gardener pulling the wheelbarrow behind him, loaded with various implements. The little boy said: "Why do you pull the wheelbarrow from behind instead of pushing it in front?" The gardener said: "I hates the sight of it so." People hate the sight of a colostomy.

Again, in regard to those cases in which you perform exploration, remember that glands are often enlarged from sepsis in carcinoma of the rectum, without cancerous glandular involvement and sometimes in such cases colostomy is done, and nothing more, because such enlarged glands are supposed to be carcinomatous. Unless you are very certain, you had better take a gland out and have it examined microscopically for there are cases of cure after radical operation in which an enlarged gland was removed and did not prove to be carcinomatous.

One point more in regard to carcinomas of the rectum; that is removal of the carcinoma in a locally operable case in which secondary tumors are present in the liver. Patients with carcinoma of the rectum suffer dreadfully when the perirectal tissues, nerves and bladder are involved, but it sometimes happens that the metastasis is in some place in which it will not become septic, and in which the pressure on nerves will not be painful, and the patients may live for a long time. In such a case, if the growth is readily operable, in order to save the patient all of that suffering while he is waiting to die from metastasis, I never have hesitated to remove the rectum even in the presence of secondary growths in the liver or the lung.

It is astonishing how long such patients will sometimes live. I have removed comparatively small carcinomas of the rectum, when secondary nodules existed in the liver, and the patients have lived several years in comfort. If the primary carcinomatous growth is removed, the secondary growth may not progress so rapidly.

ATROPHY OF THE LIVER DUE TO CINCHOPHEN PREPARATIONS

When cinchophen was introduced into therapeutics (reinforced by the trade name "Atophan"—the tophi remover) its striking effect on the elimination of uric acid captured the clinical imagination. It was soon seen, however, that Atophan belied its name for the tophi refused to be removed. The drug was found, however, to be an effective analgesic. Various esters and derivatives were advertised extensively for the benefit of those who do not like the flavor of cinchophen and for the benefit of the manufacturers who could establish a monopoly on each little change. Cinchophen became a household remedy in the belief that it could do no harm. In 1923 evidence became available that the drug was causing fatal hepatitis. Since there are many other analgesics about as effective as cinchophen in many cases, and without this insidious danger, the use of the drug should be avoided whenever possible. Unfortunately, this is not simple, for a physician may be easily led into prescribing cinchophen when he does not know it. He may avoid it under the official names of cinchophen and neocinchophen or the original, therapeutically misinforming names of Atophan and Novatophan, but can he be expected to keep in mind all the noninforming names which manufacturers invent? This illustrates the importance of the rule of the Council on Pharmacy and Chemistry which permits not more than one trade name—that applied by the discoverer. The rule protects those that use New and Non-official Remedies but can do little for others. The case is even worse for the patent medicines that are advertised to the public. While physicians, now that they have been warned, will restrict the use of cinchophen and watch for the first signs of danger, cinchophen preparations may be sold to the public in mixtures of secret composition. (Jour. A. M. A., August 2, 1930, p. 345.)

THE EARLY DIAGNOSIS AND TREATMENT OF MALIGNANCY OF THE BREAST*

Orwood J. Campbell, M.D.
Minneapolis

IT HAS long been known that any material reduction in the mortality rate from malignancy of the breast must come through earlier diagnosis and treatment, rather than through refinement of surgical or radiological technic.

For years the medical profession has been trying to impress upon the public the importance of routinely examining the breasts and promptly reporting to the physician any departure from the normal.

Viewed from the standpoint of ultimate results, particularly those obtained from the large general hospitals, this education has proven a disappointment. We are still being presented with too many late lesions.[18] Unsatisfactory results are attributable to unnecessary and preventable delay in receiving treatment. Lane-Clapon[23] found that out of 1,493 patients with cancer of the breast applying within three years of the onset of symptoms, only a little over one-half did so within six months. The mean alleged duration of symptoms was just under nine months. Of 1,447 cases with microscopic reports, 73 per cent had axillary metastases when operated. In a series of 111 cases from the University and Minneapolis General hospitals, the average duration of symptoms for those reporting within three years was nine and one-half months.

In contrast to this, a source of encouragement is to be derived from the increasingly greater number of women who are presenting themselves with few symptoms and minimal findings. McCarty, Sistrunk, Bloodgood, Floyd and Haggard, and others have noted this changing clinical picture and have attributed it to the cumulative effect of educational efforts. Whereas twenty years ago 80 per cent of presenting cases were malignant, now in most clinics, especially breast clinics, the great majority are benign.[6, 8]

With this increase in the number of patients having few symptoms and minimal findings, there has been a corresponding increase in the difficulty and the responsibility of the examining physician in correctly evaluating symptoms and advising the patient. This responsibility should be keenly felt when it is realized that, in its earliest and most curable form, malignancy presents few, if any, evidences of its presence.[12] It is a responsibility which cannot always be shifted to men especially trained to assume it, but must be accepted by the large group of practitioners. It is to this group of men that the following remarks are directed.

If one is to become proficient in the diagnosis of breast lesions, it is highly desirable that a system of examination be adopted and carried out routinely. The following commonly used method is recommended:

Without prejudicing his judgment by previous knowledge of the location of the lesion, the examiner has the patient remove her clothing to the waist and seat herself on a chair. Standing in front, he notes the relative size and weight of the two breasts, the presence or absence of dimpling of the skin, or retraction of the nipples. He inspects and palpates the supraclavicular region, noting the presence or absence of fullness and whether or not nodes can be felt.

The patient is then placed on a table with the head and shoulders slightly elevated and the hands locked behind the head. Standing at the head of the table, the examiner looks for tumor masses outlined in the breast or in the axilla, for the reddened eczematoid type of lesion of Paget's disease of the nipple, for dilated vessels beneath the skin, and for the "orange-peel" skin indicative of advanced malignancy.

The breasts are then systematically palpated against the chest wall with the flats of the fingers. Picking up the breast between thumb and fingers gives a false impression, as the normal breast lobulations then feel like tumor masses. Beginning with the periphery and finishing with the nipples, both breasts are palpated. The presence or absence of shotty or nodular areas, of definite solid or cystic tumor masses, is noted and, if present, recorded on a chart. The nipples are pulled for evidences of fixation and the areolar

*From the Department of Surgery, University of Minnesota, Minneapolis. Read before the annual meeting of the Minnesota State Medical Association, Duluth, July 16, 1930.

area searched for worm-like masses produced by dilated ducts beneath the nipple.

Finding a definite tumor, its size, shape, and the sharpness of its margins are investigated. Its consistency is determined as nearly as possible, remembering that a tense cyst or a deeply placed cyst may feel like a solid tumor. Attachment to the pectoral fascia may be ascertained by having the patient press her clasped hands together across her chest to tense the pectoral muscles. By moving the tumor, early fixation to the pectoral fascia will be evidenced by restriction of mobility. Without fixation of the muscles, attachment of the tumor may be missed by motion of the muscle itself on the chest wall.

Early attachment to the skin can be demonstrated by puckering the skin around the tumor. This maneuver will produce dimpling over the most superficial and usually the hardest portion of the tumor.

Finally, the axilla and abdomen are palpated. Axillary lymph nodes are best felt by placing the patient's arm in partial abduction and inserting the finger tips to the apex of the axilla. Nodes are then felt to slip under the fingers as the hand is moved downward against the chest wall.

A relatively recent contribution to the technic of clinical examination is transillumination of the breast, as practiced and described by Cutler. A Cameron transilluminating electric lamp, which produces little heat, is placed underneath the breast. Inflammatory masses produce diffuse opacities which fade and disappear as the inflammation subsides. Solid tumors, benign and malignant, cast shadows depending on size and location; cysts filled with clear fluid are translucent. Traumatic hematomas cast dense shadows with fading margins. Intracystic or duct papillomas associated with a discharge of bloody fluid from the nipple present a uniformly circumscribed shadow. In cases with bleeding from the nipple where no tumor is palpable, the method is especially valuable in indicating the site of the lesion and determining whether there are multiple or single lesions. The method in itself does not differentiate malignant from benign lesions.

Having obtained all the available clinical information, the examining physician is ready to consider the diagnosis and method of treatment. He will be guided by two main considerations. First, every case of operable malignancy must have the complete radical amputation. Second, as many breasts as possible should be saved.

Cases group themselves into (1) the obviously malignant; (2) the obviously benign, and (3) the indefinite group. The obviously malignant, presenting one or more clinical signs of malignancy (attachment to nipple, skin or fascia, or metastases), offer no difficulty in diagnosis. They are not early lesions and do not come within the scope of this paper. Fitzwilliams[15] has said, "Anything that has any characteristic of malignancy I no longer regard as early." If the complete operation is done in all such cases, very few unnecessary removals of the breast will occur.

It is well to remember, however, that certain benign lesions may simulate malignancy. True mastitis, and traumatic fat necrosis, may become attached to the skin. Any benign tumor situated beneath the nipple may become attached and, finally, lymphadenopathy of other than malignant origin may simulate metastases. If any of the above mentioned are suspected, it would be advisable to treat the patient as one of the indefinite group.

The obviously benign group is increasing in relative number. The percentage of benign lesions for which operation is not indicated will vary with the experience of the examiner. Bloodgood recognizes and does not operate upon 65 per cent of cases; Bartlett places 46 per cent of cases in the obviously benign group as cystic disease and is constantly increasing the percentage of those who are not operated; Johnson considered 61 per cent as safe without operation. The man with little experience will do well to place more cases in the indefinite group. If any doubt exists, at the cost of a small scar the patient may be assured of maximum protection and the physician relieved of his uncertainty through microscopic diagnosis.

The third, or indefinite group, constituting, according to McCarty, about 25 per cent of the whole, presents the greatest difficulty. In dealing with this group, nothing is more illogical than the far too common practice of observing a tumor until such time as its malignant character manifests itself clinically. The development of clinical signs is due to extension or to metastasis of tumor tissue. To urge women to report their symptoms promptly, and then to procrastinate until they have lost their best op-

portunity for a cure, is a gross inconsistency and an inexcusable betrayal of trust.

The exploratory incision meets the requirement of accurate diagnosis at an early stage. With the patient prepared for the complete operation, the tumor or suspected area, together with a generous amount of surrounding breast tissue, is removed through a small incision. Immediate diagnosis is made by frozen sections. In the event of malignancy, the wound is cauterized to destroy any loose tumor cells, and the complete operation performed. There is no evidence that this procedure reduces the patient's chance of a cure. There is considerable evidence that a delay between the time of local excision and complete operation diminishes this chance. Harrington showed that there is a 5 per cent better prognosis over a five year period where no interval elapses. Unless an operator has the facilities for frozen tissue technic and access to the services of a competent pathologist, cases in this indefinite group should be referred elsewhere.

Let us now consider a rational course of procedure based upon the various clinical pictures most frequently found. Authors of extensive experience disagree widely in their attitudes on certain clinical pictures and pathological findings. The following represent the writer's conclusions in the light of his own and the accumulated experience of others.

Pain in itself is of little or no value in the differential diagnosis of malignancy.[3] It is common in early benign, rare in early malignant lesions. Its principal value is in calling the patient's attention to a lump in the breast, and in sending her to a physician.

Discharge from the nipple may occur in either benign or malignant lesions.[1, 14, 28, 29] It is not, as sometimes thought, diagnostic of malignancy. In the absence of clinical signs of malignancy, a tumor associated with discharge from the nipple should be excised for diagnosis. The majority of such lesions will be intracanalicular papillomas or cystadenomas, but a few will be malignant. In the absence of palpable tumor, transillumination will often reveal the duct and small tumor from which the bleeding is occurring. This area should also be excised for diagnosis.

Eczematoid lesions of the nipple associated with a tumor beneath indicates Paget's cancer of the breast and the radical operation should be performed.[9, 30]

In the absence of a palpable tumor, when the lesion on the nipple is very early, appearing more as an irritation, protective dressings may be applied in an effort to bring about healing.[7] If the effort is not entirely successful in three weeks, or if the lesion is well established at the outset, the nipple, areola, and a generous area of breast beneath should be excised and carefully examined for signs of cancer. In the absence of suspicious tumor in the duct region, no further operative procedure is indicated. The breast should thereafter be examined at frequent intervals.

Tumors in women under the age of twenty-five: Malignancy of the breast under the age of twenty-five is rare. If the dividing age be further reduced to twenty, there would seem to be no urgency in removing a tumor unless it is growing rapidly.[7] The most common single tumor occurring under the age of twenty-five is the encapsulated fibroadenoma. Fibroadenomas may undergo sarcomatous change. Later in life, complicating pregnancy, they may be wrongly diagnosed as carcinoma and cause the unnecessary loss of the breast. It is the writer's opinion that definite tumors are better removed. One should be very critical of the clinical signs of malignancy in patients under the age of twenty-five. In illustration of this point: A young woman presented herself at the University Hospital with a small hard tumor above the nipple zone and with enlarged hard glands in the axilla. On the basis of the rarity of carcinoma in her age group, a diagnosis of mastitis and tuberculosis of the axillary lymph nodes was made. Diagnostic exploration verified this original diagnosis and a breast with classical signs of malignancy was saved.

Tumors in women over the age of twenty-five: All single definite tumors in which the clinical signs of malignancy are absent should be removed and diagnosis immediately established by means of frozen sections. Such tumors will include various types of cancer, sarcoma, fibroadenomas, cysts of benign or malignant origin, localized areas of cystic disease, traumatic fat necrosis, and some inflammatory processes.

When inflammatory carcinoma of the breast is suspected, no operative procedure should be carried out. This type of cancer is so malignant

that surgery is contraindicated. Palliative *x*-ray treatment is all that can be offered.

The practice of aspirating a cyst to determine the character of the fluid is to be condemned on the grounds that cancer may exist in a cyst containing clear fluid.[2, 3]

Dilated ducts beneath the nipple, when bilateral and unassociated with definite tumor or retracted nipple, can be considered benign and kept under observation.

Multiple definite tumors, shotty or nodular breasts are usually manifestations of various types of cystic disease, commonly called chronic cystic mastitis.

Is cystic disease a precancerous lesion?

Evidence based on the microscopic examination of various types, particularly the adenocystic type in which epithelial hyperplasia predominates, has led many pathologists and surgeons to regard this disease as definitely precancerous and to recommend a simple amputation of the breast.[11, 15, 21]

Evidence based upon the follow-up of cases in which no operation, or local excision only, was performed, and in which over a period of years only the normal incidence of cancer occurred, has led others to consider the disease benign and to save the breasts.[5, 6, 7, 8]

In 1925 the writer, tracing cases from the records of the University Hospital and University Department of Pathology, found that no cancers had subsequently developed in cases for which no operation or local operation only for cystic disease had been performed. The writer feels that the rationale of treatment in cystic disease is based upon the difficulty in distinguishing between cystic disease and cancer rather than upon any predisposition to malignant change.

When both breasts are uniformly shotty or nodular, with no one area more definite and distinct than another, it would seem safe to forego operation. Mistaken diagnosis in such cases can do no real harm since bilateral diffuse cancer occurring simultaneously is incurable. Since cancer can occur in a breast containing diffuse cystic disease, any definite tumor present or arising in a diffuse indefinite process should be removed for frozen section diagnosis. Multiplicity of tumors is highly indicative of a benign process but does not rule out malignancy. The writer prefers to remove one or more of the most suspicious lumps. Since cancer developing in such a breast will more easily escape early detection, simple amputation might be justifiably recommended for older women, in whom the loss of the breast is less of a misfortune.

Without operation, unilateral and localized areas of cystic disease should be infrequently diagnosed by those with limited experience. The differentiation between infiltrating cancer mastitis and cystic disease is too uncertain without the aid of the microscope.

Along the line of technic, the writer desires to point out a commonly disregarded principle which was long ago advanced by pioneers in surgery of the breast, namely: the tumor should occupy the center of the block of tissue removed. A common error is that of making the incision to fit the breast rather than to fit the tumor.

In conclusion, those physicians who have not acquired a thorough knowledge of breast lesions and their proper management are urged to do so if they are to fulfill their obligation to the community and to the profession.

MALIGNANT LESIONS OF THE KIDNEYS, BLADDER, PROSTATE GLAND AND TESTES*

WALTMAN WALTERS, M.D.
Rochester, Minnesota

A CONSIDERATION of malignant lesions of the urogenital tract necessarily includes malignant tumors of the kidneys, bladder, testes, epididymis, spermatic cord and penis. Since it would be impossible to consider the malignant lesions involving all of these structures in one short paper, I am concentrating on the group of lesions which appear with greatest frequency; I refer particularly to malignant lesions of the prostate gland, kidneys and bladder.

I might first say, briefly, that tumors of the epididymis, spermatic cord and testicular tunics are, for the most part, benign (approximately 70 per cent). Malignant tumors in these situations are almost exclusively sarcomatous. The growth of most tumors of the spermatic cord is extremely slow. They are not painful and frequently the patient is not aware of their existence until trauma calls attention to them. Similarly malignant tumors of the testes are relatively rare. They constitute a proportion of only 5.8 in each 1,000 of all malignant tumors in men, according to the mortality statistics of the registration area of the United States. Of even greater rarity are malignant tumors of the epididymis; these are more of academic than of clinical significance. Tumors presenting themselves in these areas should be removed surgically. It has been the practice in The Mayo Clinic to supplement surgical extirpation of malignant tumors from these areas with the application of roentgen rays to the regional lymphatics. There are in the records of the clinic many cases in which patients with malignant testicular tumors, graded 4, are living and well three years or more after such treatment.

CARCINOMA OF THE PROSTATE GLAND

The most common cause of increase in size of the prostate gland is simple enlargement due to fibroadenomatous hypertrophy. The incidence of carcinoma of the prostate gland, compared with that of simple benign hypertrophy, is given by Thomson-Walker as 13.5 per cent, but in cases referred to the clinic, the relative proportion of benign to malignant lesions of the prostate gland is somewhat greater.

The diagnosis of carcinoma of the prostate gland can be made, in most cases, by palpation of the gland by rectum. Such a gland imparts to the palpating finger an impression of nodular induration or stony hardness, fixation, and frequently of extension of the growth to adjacent tissues. The last characteristic gives the gland an ill-defined margin. Occasionally chronic infection producing prostatitis will increase the consistence of the gland to the extent that one may suspect it to be carcinomatous. Similarly, prostatic calculi of small or large size may change the contour, configuration and consistence of the gland, so that the erroneous impression is gained that a malignant lesion exists.

The most common symptoms of carcinoma of the prostate gland are frequency of urination and perineal pain. In the latter stages of the disease, urinary obstruction may occur. The frequency with which small but diffuse carcinomatous glands metastasize to bone must be remembered, for occasionally such painful metastatic growths may be the first clues to the presence of prostatic carcinoma.

In a study of 1,000 cases of carcinoma of the prostate gland, in which treatment was carried out at the clinic prior to January, 1925, Bumpus found demonstrable metastasis in 24 per cent of the cases. The most common sites of the metastasis were regional as well as remote portions of the lymphatic system, whereas the next most common sites of metastasis were structures of the bony pelvis.

In a consideration of the treatment of malignant growths of the prostate gland, it should be remembered that there are two distinct clinical forms. In the primary type, the gland may be said to have been carcinomatous from the beginning of the change, whereas in the secondary type the characteristics are those of benign fibroadenomatous hypertrophy with secondary malignant changes. It is in the second group that surgical removal of the gland has given the best results. Cases in this group form no small per-

*From the Division of Surgery, The Mayo Clinic, Rochester, Minnesota. Read before the Minnesota State Medical Association, Duluth, July 14 to 16, 1930.

centage of all cases of carcinoma of the prostate gland and their incidence has been reported by Albarran and Hallé to be 14 per cent and by Thomson-Walker to be 18 per cent among the cases of prostatic carcinoma seen by them. In a follow-up study of ninety-six cases in which prostatectomy was performed and in which malignant portions were found on examination of the gland, Thomson-Walker reported that malignant growth had recurred in only 3 per cent.

It has been the custom at the clinic to advise and to carry through prostatectomy, either by the suprapubic or perineal routes, in cases of prostatic enlargement due to carcinoma whenever there has been sufficient evidence that the carcinomatous process has not extended too widely beyond the periphery of the gland. This of course automatically eliminates from consideration for prostatectomy any cases in which metastasis has occurred. On a few occasions a gland which had the appearance of being the site of early carcinomatous enlargement, when removed proved to be affected by simple prostatitis or prostatitis with calculi. In other cases, particularly in cases of carcinoma of the primary type, removal of the obstructing portion of the gland, although it does not completely remove the carcinoma, often will relieve urinary obstruction and dysuria for months, and sometimes for years, before cystostomy becomes necessary. In cases of unremovable carcinomas of the prostate gland, permanent suprapubic cystostomy not only serves to relieve the urinary obstruction but may furnish the patient many months of comfortable life. It may or may not be combined with treatment by radium, but in our experience it has been difficult to evaluate the effect of radium in such cases. In many cases of carcinoma of the prostate gland the only symptom is perineal pain. The value of roentgen rays applied through the perineum, as a method of relieving some of these patients of their perineal pain, should be stressed. However, if relief is not obtained, extirpation of the hypogastric ganglia, as suggested by Learmonth, is worthy of consideration.

In an evaluation of the results of treatment for malignant disease, the characteristics of the malignant lesion, its situation, its rapidity of growth, its extension into surrounding structures, and its tendency to metastasize, must be considered. In the treatment of malignant disease of a given situation, one should be concerned not only with the desire completely to eradicate the malignant process but also should be on the alert to remove or destroy recurrences at an early time and to relieve obstruction and pain.

It is to be expected that in patients with primary carcinoma of the prostate gland, life will not be prolonged as much as in cases of secondary involvement. Yet, even in inoperable cases, the relief of urinary obstruction by introduction of a suprapubic cystostomy tube is of distinct benefit to the patient. Besides, there is an occasional suitable case in this group in which operative removal of the gland will be followed by good results. Of 164 patients with carcinoma of the prostate gland, who were operated on at the clinic, and concerning whom records are available, Bumpus found that thirty-five were still alive in 1925 and that twenty-one of them had lived longer than five years. The best results following enucleation of the carcinomatous prostate gland will be in the cases of so-called secondary carcinoma, if metastasis has not occurred. In a study of sixty-six cases, in each of which a prostate gland with malignant portions was enucleated, Thomson-Walker found evidence of recurrence of the carcinoma in only 3 per cent. Much depends on the proper selection of cases for the various procedures. Experience in handling such cases will aid in making choice of the best method of attack.

MALIGNANT TUMORS OF THE KIDNEYS

Adenocarcinoma or hypernephroma constitutes practically all malignant tumors of the kidney, with the exception of the primary squamous-cell epithelioma of the pelvis of the kidney, which in proportion to the adenocarcinomas exists in the relation of from 1:11 to 1:14.

Sarcoma of the kidney is relatively rare. In an unselected group of 225 cases of malignant tumor of the kidney in which operation was performed at the clinic, only ten of the tumors were sarcomas. The assumption that sarcoma of the kidney occurs chiefly in young adults has not been borne out in our experience. For example, eight of ten patients with sarcoma of the kidney were adults, whereas the tumors in a series of thirteen children with malignant tumors of the kidney were reported by the pathologist as adenocarcinoma, sarcoma and Wilms' tumor.

Lumbar pain, the presence of a tumor in the region of the kidney and hematuria are the triad

of symptoms present in practically all cases of malignant tumor of the kidney. In a group of 367 cases of carcinoma of the renal cortex reported at the clinic by Judd and Hand, one of these symptoms was present in 99 per cent.

Adenocarcinoma of the kidney is associated with tortuous, dilated veins in the fatty capsule surrounding the lesion. In the early stages, adenocarcinoma is limited to the poles of the kidney and as the lesion extends by growth the entire kidney may be involved. Later, the capsule may be broken through and the perirenal tissues become involved, extension sometimes occurring into the renal veins. When metastasis occurs, it involves the lungs, the lymph nodes, the liver, the skeleton, the brain, the spinal cord and the pleura, in decreasing frequency in the order named.

In 192 cases of malignant tumor of the kidney in which nephrectomy was performed, the average duration of symptoms before operation varied from seventeen to twenty-one and a half months. Ninety-one of the 192 patients on whom nephrectomy was performed are still living, and yet the average duration of their symptoms before operation varied from thirty to forty months. In a series of 250 cases in which nephrectomy was performed for adenocarcinoma of the kidney at the clinic, twenty-six patients have lived ten years or more. The association of lumbar pain, enlargement of the kidney and hematuria in more than 99 per cent of cases of malignant tumor of the kidney, and the fact that the duration of life and the completeness of cure are proportionate to the degree of malignancy and the size of the malignant lesion of the kidney should serve as a plea for earlier diagnosis and treatment of this lesion after conclusive proof of its existence has been established.

It is probably unnecessary to emphasize the absolute necessity of cystoscopic examination of patients with hematuria. In the presence of such a history, the burden of proof that a malignant tumor is or is not present in the bladder or in the kidneys lies directly on the examining physician, and the only accurate method of determining or of eliminating these possibilities is by cystoscopic examination and the other refinements of urologic diagnosis, such as pyelography. If there is a question with regard to the nature of the lesion in the bladder, a specimen should be removed for microscopic diagnosis at the time of the cystoscopic examination.

I am observing a patient in the hospital at the present time whose condition illustrates the foregoing points. The patient had been in perfect health until two months ago, when he noticed gross hematuria on two occasions. Subsequently, the urine became clear, although a few erythrocytes were found in the urinary sediment on microscopic examination. Cystoscopic examination revealed a normal appearing bladder. A pyelogram of the right kidney was negative, and that of the left showed obstruction at the ureteropelvic juncture. Exploration of the left kidney was advised and after a great deal of persuasion because of the absence of symptoms, with the exception of hematuria, and his opinion that he was in excellent health, the patient gave his consent for operation. The interior of the kidney was filled with papillary squamous-cell epithelioma, which was confined entirely to the pelvis and calices, and nephro-ureterectomy was done. The prospects for permanent cure in this case are excellent, due to the early recognition of abnormality in the kidney and the complete removal of the kidney as well as the path of the extension of the papillary squamous-cell epithelioma down the mucous membrane of the ureter.

Papillary squamous-cell epitheliomas of the renal pelvis are relatively uncommon as compared with the solitary cortical tumors, as has been previously stated. Squamous-cell epitheliomas differ in degree of malignancy, as do all malignant tumors. The degree of malignancy may be accurately determined by Broders' index. The tendency of papillary epithelioma in the renal pelvis to extend directly along the mucous membrane of the ureter to the bladder necessitates ureterectomy at the time or soon after the removal of the affected kidney. This tendency of direct extension down the ureter, rather than metastasis to distant structures or invasion of perirenal tissues, makes papillary epithelioma of the renal pelvis less malignant than the cortical tumors, degree for degree.

In summarizing this brief consideration of malignant renal tumors, I wish to emphasize again the truly excellent results which have followed nephrectomy. Quoting again from the statistics of the clinic as summarized by Judd and Hand in a group of 283 unselected cases of

malignant tumor of the kidney in which nephrectomy was performed, in 106 cases the patients lived from three to twenty-two years, whereas ninety-one patients (almost 33 per cent) are living and well an average of more than five years after operation.

It has been found difficult in the clinic to estimate the value of roentgen rays and radium, or both, as additional aids to surgery, since these are agents used only in cases in which there is extensive involvement of the perirenal tissues and in which it is felt that all of the tumorous tissue has not been removed.

MALIGNANT TUMORS OF THE BLADDER

Epitheliomas comprise approximately 95 per cent of the lesions of the bladder. They vary in degree of malignancy (grades 1 to 4). The most common symptom of a malignant tumor of the bladder is hematuria, although frequency of urination and dysuria may lead the patient to seek diagnosis before gross hematuria is noted. The necessity for a cystoscopic examination, the elimination of the kidneys as the source of the bleeding and the removal of a specimen from a suspected lesion for microscopic examination are obvious. Methods of treating malignant tumors of the bladder should depend on their relative degree of malignancy, their size and their situation. Most tumors of the dome or lateral and posterior walls of the bladder are operable and lend themselves readily to excision or resection. If a lesion situated in one of these areas is of a high degree of malignancy, that is, graded 3 or 4, and is infiltrating, segmental resection is indicated of that portion of the bladder and also of the normal portion of the bladder for a distance of at least 1 cm. at the periphery of the growth. On the other hand, tumors of lower degree of malignancy often lend themselves to local excision or, if of small size, to electrocoagulation through the cystoscope. Tumors in the base of the bladder are usually not resectable because of involvement of one or both ureters. Lesions of a low degree of malignancy involving this area can many times be completely and permanently eradicated by the employment of the actual cautery or by electrocoagulation. Bumpus reported a series of thirty-six cases in which extensive inoperable tumors of the bladder involving the base and the ureteral orifices were destroyed by cautery; seven patients in this series have lived for more than four years and one has lived for nine years. There is no doubt of the value of the transvesical electrocoagulation of tumors involving the base of the bladder, especially if they are highly malignant.

In a group of fifty-one cases of this type with involvement of one or both ureteral orifices or the internal urethral orifice, twenty-two patients have remained free from recurrence from six months to more than three years. Comparable results in similar cases by electrocoagulation were reported in the symposium of tumors of the bladder by Kretschmer at the 1930 meeting of the American Medical Association.

The tendency of malignant tumors of the base of the bladder to obstruct the ureteral orifices, with resulting degeneration of the renal parenchyma, has led to a critical estimation of the value of external ureterostomy, bilateral nephrostomy or ureteral transplantation into the sigmoid. The excellent results obtained by the transperitoneal method of ureteral transplantation into the sigmoid at low operative risk by the C. H. Mayo method in cases of exstrophy of the bladder, the bilateral simultaneous ureterosigmoidal implantation described by Coffey, and the extraperitoneal transplantation of Cabot have reawakened interest in this method of treating extensive inoperable tumors involving the base of the bladder which have not responded to direct methods of attack. After the transplantation of the ureters in these cases, the use of massive doses of radium or of complete cystectomy offers the possibility of cure of the malignant disease, provided metastasis to the regional lymph nodes has not occurred, and at least offers relief from the distressing dysuria and hematuria for which patients seek relief.

Small tumors of the bladder of a low degree of malignancy are often best treated by electrocoagulation through the cystoscope. If the tumor is highly malignant and not large, transurethral electrocoagulation can often be done satisfactorily for it has been frequently demonstrated that malignant cells cannot withstand abnormally high degrees of heat.

Following the treatment of the malignant lesions of the bladder, patients should be ex-

amined at regular intervals, usually every three months the first year and every six months the second, to determine whether or not the tumor has recurred. This can only be determined by cystoscopic examination. Such recurrence or extension of the tumor usually occurs in the form of small implants and can be easily destroyed by electrocoagulation carried on through the cystoscope.

The results of treatment of epithelioma of the bladder in which curative surgical measures were carried out in the clinic in 370 cases have been summarized by Hunt. The study indicated that results are dependent on the site of the tumor, its extent, and the degree of malignancy. In cases in which the malignant lesions were graded 1 or 2, and in which the lateral walls of the dome were involved, 73 per cent of patients were living and well three or more years after operation, whereas 50 per cent of patients with tumors involving the base of the bladder of similar degree of malignancy had been without recurrence for a similar period. In cases of the most malignant tumors, graded 3 or 4, there is proportionate or corresponding decrease in good results of treatment. In 42 per cent of cases in which the tumors were graded 3 or 4 and in which the lateral walls of the dome were involved and in 25 per cent of cases of corresponding degrees of malignancy in which the base of the bladder was involved, the patients have been without recurrence for a period of more than three years.

DISCUSSION ON SYMPOSIUM ON THE DIAGNOSIS AND TREATMENT OF CANCER

DR. W. J. MAYO (Rochester, Minn.): We think of cancer in connection with man, but all living things, plant and animal, suffer from analogous conditions at some point in the bodily structure at which their condition of life or habits interferes with the protective mechanism. The late Dr. Erwin Smith, in the Department of Agriculture at Washington, made a life study of plant cancer and discovered certain microörganisms which appeared to be its cause, or which at least prepared a field for its development. The theory that cancer in man was due to a microörganism which entered the human body at some point of local lesion was at one time very popular and many supposed germs, bacterial or protozoa, were discovered. This theory, on further investigation, was discarded. If parasitic agents are the cause of cancer, why, for instance, are metastatic growths in the liver from cancer of the stomach, not cancer of the liver? As a matter of fact, they are cancers of the stomach in the liver. Obviously the diseased cell from the original tumor has been transplanted to the liver.

In a consideration of the development of cancer, three facts are closely related: (1) a local point of origin; cancer never appears in sound tissue, (2) there is a change in the cells of the part affected, and (3) a striking variation in the susceptibility of persons to the development of cancer; in some, under no conditions, will the disease develop; in others, it appears on the slightest provocation. In relation to this third fact our ultimate hope is that some method may be evolved whereby low resistance may be raised to high resistance, or even immunity may be established.

The local lesions in which the effectiveness of the bodily protection has been reduced, fall into three types: (1) small tumors, moles and warts, and neoplasms which are not originally cancer but may become so; (2) injuries (sarcoma often follows on the site of a contusion), and (3) most common, chronic irritation.

Investigation of the various theories of the causation of cancer shows that the one provocative agent which remains unchallenged is chronic irritation. In all lands, among all peoples, we see this one causative influence in the ascendant. In China, among those who shave their heads with a dull and rough-edged razor, cancer of the scalp is common, but does not occur among those who do not shave the scalp. The Chinese men eat at the first table, when the rice is hot, throwing it with some force by means of chopsticks into the mouth and pharynx, and not infrequently they suffer from cancer of the pharynx and of the beginning of the esophagus. The women, who eat at the second table, when the rice is cold, seldom have the disease. In Australia the sharp-edged sand in the desert portion of the country, blown by the hot wind, so frequently produces cancers of the skin of the face that such cancers are called the "Australian disease." In certain parts of India and the Philippines, where the betel nut, wrapped in its leaf with lime, is chewed, cancer of the mucous membrane of the cheek is still common. Among smokers, cancer of the lip sometimes develops, less commonly since heat-conducting clay pipes are no longer used. Cancer of the gums and about the teeth is less common now that by modern methods of dentistry irritating stumps and roots may be removed. Cancer of the breast occurs largely among civilized women. In those countries in which the breasts are allowed to be exposed, that is, are not compressed or irritated by covering, it is rare. In the mountain regions of Kasmir, India, where the people carry braziers filled with hot coals strapped onto the lower part of the abdomen, in going from the valleys into the cold mountains, cancer just above the pubes is common.

With improvements in construction of buildings and changes in fuel, there are no longer many chimneys which require cleaning, so that chimney-sweep's cancer of the groin is less common, but we still see an occasional cutaneous epithelioma on the shins of railroad engineers and firemen whose legs have been exposed during years to the intense heat of the engine firebox.

I have merely touched on those few outstanding examples of cancer of visible parts of the body about which there is little dispute. As to cancer of the interior of the body we have less definite proof. Cancer in the internal protective mechanism of the body is encouraged by injuries to the local protective mechanism. Cancerous gallbladders usually contain stones. Gallstones are three times as common in women as in men, and cancer of the gallbladder is found in about the same proportion.

That ulcer of the stomach or some analogous condition may be responsible for cancer of the stomach is admitted by all, although there are great differences of opinion as to the frequency of cancer from this cause. Hurst has given statistics to show that in about 20 per cent of cases of ulcer of the stomach, cancer may be expected. In our experience, although the percentage in which the histologic examination of excised cancers of the stomach for evidence of preceding ulcer varies in different series of cases, evidence of the development of gastric cancer on some type of demonstrable precancerous disease, such as ulcer, is present in more than 25 per cent. Ulcer of the stomach will be revealed by a considerable percentage of resections for cancer of the stomach.

Cancer of the stomach is rather rare in uncivilized races and in animals. It is the base of nearly a third of the total number of cancers of civilized man, and perhaps taking foods and fluids too hot, hotter than can be held comfortably in the mouth, may have something to do with this.

Cancer of the ovaries is common, and cancer of the testis is uncommon. The testis is the primitive organ from which the ovary is derived, and has a greater resistance than the ovary, just as the small intestine, by reason of its primitive character, has greater resistance than the large intestine and rectum.

Both the uterus and the breasts are most likely to undergo cancerous change at about the period of meno-

pause, indicating that the age of senile cells acts as an invitation to the disease.

As bearing on the question of heredity and susceptibility, it is interesting that although there is great variation as to the organs affected, in the statistics from various civilized countries, the total percentage of those who have cancer for the same age periods is about the same.

In thinking of cancer we must keep clearly in mind the distinction between a local lesion which may undergo malignant change, but which is as yet without cellular alteration, and those conditions which we speak of as "precancerous," in which cellular changes have taken place, but which have not invaded the surrounding tissues in characteristic fashion.

The lesson that is to be learned is that local lesions which give opportunity for cancer are to be cared for early, that precancerous lesions are to be taken care of skillfully, and that treatment of early cancer either by the knife or radioactive agents, alone or combined, gives a high percentage of cures (79+ per cent).

In conclusion, I will touch on the fear of cancer which is so prevalent as frequently to cause patients to delay examination of a tumor or suspicious area because they believe that cancer is incurable. Of patients operated on before metastasis has taken place, nearly 80 per cent are cured permanently. Unfortunately the man who has been cured of cancer conceals the fact as he would a prison sentence, because he understands that it would interfere with his future advancement, whereas those who seek medical aid too late cannot conceal their condition, and therefore the laity form an exaggerated idea of the hopelessness of the disease.

Dr. E. Starr Judd (President-elect, American Medical Association): Mr. President and members of the Minnesota State Medical Association: I have been very much interested in this symposium on carcinoma.

The first paper I heard was that by Dr. Campbell, and I think that he brought out the most important points in the early diagnosis of carcinoma of the breast. We have long realized in the clinic that if we found a tumor of the breast to be attached to mammary glandular tissue or to the skin that this finding established the diagnosis of carcinoma and Dr. Campbell has brought this out especially well today.

If one looks back in the old textbooks, or in some of the modern ones, he will find that serosanguineous discharge from the nipple is considered to be a positive sign of carcinoma of the breast. Dr. Dean Lewis called our attention to the fact that unless this symptom is associated with a tumor of the breast, carcinoma probably is not present. In other words, if there is tumor of the breast, and bleeding from the nipple, carcinoma is probably present; if there is no tumor in the breast in the presence of bleeding or serosanguineous discharge from the nipple, then the condition is more likely to be due to intracanalicular papilloma, which is practically always benign, or else it is due to chronic cystic mastitis.

There are two points in Dr. Walters' paper that I want to mention. One regards tumors of the testis. All of the tumors of the testis for which I have operated have been of the Ewing type. Ewing called attention several years ago to the fact that all tumors of the testis are really teratomatous, or mixed-cell tumors. Some of them are predominately sarcomatous; that is, connective tissue elements predominate. In others, endothelial cells predominate. All of these tumors are malignant. They metastasize to the lymph nodes in the retroperitoneal region. It is not necessary to perform radical removal of the cord and the retroperitoneal lymph nodes. Removal of the testis, followed by roentgen therapy over the posterior lymph nodes, frequently will give eight to ten years of comfort. Some patients seem to have been cured. If there is recurrence of the testicular malignancy in the retroperitoneal lymph nodes, it will frequently respond to treatment by roentgen rays and the patients can be made comfortable for a long time.

The other subject I want to discuss in Dr. Walters' paper is carcinoma of the prostate gland. I think that we owe a great deal to the late Dr. Geraughty, who was a St. Paul boy and who worked in the Brady Institute. He added much to our knowledge of the pathologic changes in the prostate gland. Carcinoma of the prostate gland invariably originates in the posterior lobe. In association with the carcinoma there may be adenomatous hypertrophy. Besides doing as Dr. Walters recommended, I think suprapubic cystostomy and removal of the benign adenomatous hypertrophic tissue frequently will enable the patients to urinate and to get along fairly well for a number of years.

THE EFFECT OF LIVER AND LIVER EXTRACT UPON THE SYMPTOMS AND SIGNS REFERABLE TO THE NERVOUS SYSTEM IN PERNICIOUS ANEMIA*

B. M. Baker, Jr., M.D., James Bordley III, M.D., and W. T. Longcope, M.D.
Baltimore, Maryland

LESIONS of the central nervous system are extremely common, in pernicious anemia, occurring, for instance, in Waltman's series of 150 cases in something over 80 per cent. They lead to serious effects which often incapacitate the patient or actually endanger his life.

A matter of great importance in the treatment of pernicious anemia by liver, as developed by Murphy and Minot, is the effect of this treatment on the combined degeneration of the spinal cord or funicular myelitis or myelosis, as Henneberg calls it. During the last few years many reports have been published on the subject but it is possible to refer to only a few at this time.

Minot suggested in the first report on the treatment of his 105 cases that the nervous symptoms might improve. Others, such as Sturgis and Isaacs, Ordway and Gorham, McAlpine, and especially Syderhelm are pessimistic. Syderhelm goes so far as to say that the liver diet has no effect on the symptoms referable to the combined degeneration, and that in spite of relief from anemia the disease progresses to a pernicious myeloencephalotoxicosis.

There are, however, an increasing number of reports in the literature which show that remarkable or even phenomenal improvement may take place both in the symptoms and signs referable to the lesions in the nervous system. One of the most striking cases has been reported by Bubert. Schilling, reviewing his eighty cases of pernicious anemia treated by liver, states without details, that improvement in nervous symptoms frequently occurred. A careful study has been published by Ungley and Suzman in Brain for September, 1929. They review sixty-one cases of pernicious anemia, all of which showed nervous symptoms and 30 of which were treated by liver. In 63.9 per cent the first symptom was referable to the nervous system. I shall not recount the various symptoms and signs in their series, but be content with the statement that the symptoms were referable to lesions in the posterior columns, the lateral pyramid tracts or to combined degenerations. Of the thirty patients treated with liver, seventeen improved, eight were unimproved and five died. Of the thirty-one patients that were not treated by liver, three were unimproved and twenty-eight died. Eight of the seventeen patients that improved are at work. Numbness and tingling present in all thirty cases disappeared completely in ten. Girdle sensation disappeared; incoördination and ataxia disappeared in ten cases. Changes in cutaneous sensation, present in twelve, became normal in eight. Astereognosis, present in two, disappeared in one. The knee jerks remained unchanged. Babinski reactions, present in nine, disappeared in five. Disturbances of micturition, present in seven, disappeared in six. These, we think, are the most encouraging figures published up to the present time, although by McAlpin they are considered optimistic.

We can summarize briefly the results that we have observed in forty-four cases of pernicious anemia with nervous symptoms, treated by liver and liver extract.

Among these forty-four cases, there were examples of practically all of the common symptoms and signs referable to the nervous system in pernicious anemia; and in addition some manifestations that are decidedly rare.

Numbness and tingling occurred in thirty-five, absent or diminished vibratory sense in thirty-three, weakness in forty-five, ataxia in twenty, Romberg's sign in fifteen, spasticity in nine, hyperreflexia in seven, hyporeflexia in nine, plantar extension in ten, disturbed cutaneous sensibility in eight, sphincter disturbance in seven, psychic disturbances in eight, loss of potentia in five, paralysis of the diaphraghm in one.

Though all of the patients have been treated

*From the Department of Medicine of the Johns Hopkins University, School of Medicine, Baltimore. Read before the annual meeting of the Minnesota State Medical Association, Duluth, July 14, 1930.

with liver, or a combination of liver and liver extract in large amounts, it has not been possible to follow all of them accurately, or for a sufficient period of time, to determine what result the treatment may have had; for the duration of treatment has seemed to us of great importance as affecting the continued and satisfactory improvement of symptoms.

For convenience we have considered the results of treatment in three groups of cases. The first group comprises those cases that have been treated by liver or liver extract for less than six months; the second group comprises those cases that have been treated for more than six months; and the third group comprises eight cases of outspoken combined degeneration that have been treated for ten months.

In the first group there were twenty-one patients who were treated for less than six months. Exclusive of improvement in weakness, an observed improvement took place in the signs and symptoms in 31.25 per cent. In the second group, comprising the patients that were treated for more than six months, there were twenty-three cases. In this group, improvement in both the nervous symptoms and the signs referable to involvement of the nervous system was more frequent and occurred in 55.17 per cent. In the third group, consisting of the eight cases of outspoken subacute combined degeneration which were treated for more than ten months, the improvement was frequently remarkable and occurred, according to symptoms and signs, in 58.93 per cent.

The definite improvement or disappearance of such objective signs as spasticity, plantar extension and changes in cutaneous sensibility which occurred frequently in these groups of cases must lead to the conclusion that some regression has taken place in the lesions affecting the nervous system.

Another point which has impressed us is the rapid return of symptoms and signs when the liver is reduced or is actually omitted from the diet. This has occurred in several instances, and we have noted a second period of improvement when proper amounts of liver were added to the diet. We have further observed the most favorable results in those patients who have conscientiously consumed large quantities of liver and liver extract daily. We have thought that 400 grams of liver daily, or its equivalent, was essential, and many patients have taken more. Furthermore, the patients whose blood counts have remained above or about 5,000,000 are the ones who have shown the most pronounced and the most continuous improvement.

When one considers the results of treatment by liver obtained in such a series of patients, it becomes evident that the changes in the central nervous system in pernicious anemia are not always irreparable. This seems to be true, even though the symptoms and signs have been present for weeks, or sometimes months, before treatment is instituted. We know now, as Henneberg has pointed out, that the lesion is not a sclerosis but a focal degeneration of the myelin sheath or of the axone which, as the process increases, spreads upwards in the posterior column and down in the pyramidal tracts. According to Henneberg, the lesion is different from that in tabes, inasmuch as the posterior roots are not involved. An increase in glia fibers, such as one sees in multiple sclerosis, does not occur; and all authorities are now agreed that the lesion is entirely of a degenerative nature.

There is still dispute as to whether the axis cylinder or the myelin sheath is first involved. There is also considerable evidence being accumulated to show that the lesions are by no means confined to the spinal cord. A few cases have been described in which anatomical lesions were found in the peripheral nerves and brain. Mathieu, reporting a case of pernicious anemia showing changes both in the peripheral nerves and spinal cord, suggests that the weakness and alterations in cutaneous sensibility may, in many cases, be due to peripheral neuritis. McAlpine, in discussing the matter recently, has called particular attention to certain symptoms and signs affecting the cutaneous sensations and reflexes that can be best explained as due to peripheral neuritis. It has further been suggested that the process is somewhat analogous to beri-beri and to pellagra, in which degenerative lesions have been observed in the spinal cord as well as in the peripheral nerves. Psychoses, usually manifested by depression, and ideas of persecution are not uncommon in pernicious anemia, and occurred in a fair proportion of

our cases. A view, therefore, which is rapidly becoming prevalent is that, in pernicious anemia, all parts of the nervous system may be affected, peripheral nerves, cord and brain.

One view as to the cause of these lesions, which has recently been advanced, is that the changes in the nervous system are dependent, as they are in beri-beri, upon a vitamine deficiency. Indeed, as one studies these cases of pernicious anemia, as well as the cases of sprue, it seems more and more probable that the defect which brings about the symptoms is analogous to a vitamine deficiency, or at least some deficiency which is supplied by liver or liver extract, by meat digested with normal gastric juice, or by the normal gastric mucosa of such animals as the pig. It is known that the immediate cause of beri-beri, and probably of pellagra, is a deficiency of vitamine B, and it has been shown further by Cogwill and by Gilder, Kattwinkel and Castle that lack of the anti-neuritic principle of vitamine B in the diet will result in extensive multiple degenerations of the peripheral nerves, spinal cord and brain, in dogs. These experiments suggested to them that, in some way vitamine B deficiency might be accountable for the alterations in the nervous system in pernicious anemia. We have been told, indeed, that for many years some practitioners have used yeast in the treatment of their cases of pernicious anemia with nervous symptoms. Recently, however, we have seen one such case in which yeast had been substituted for a time for liver, but with rapid progression of the nervous symptoms.

It seems, therefore, that there is considerable evidence to show that, in pernicious anemia, acute degenerations may occur not only in the spinal cord but in the peripheral nerves and brain; and, though these are analogous to the changes occurring in beri-beri and other forms of vitamine deficiences, there is no direct evidence to indicate that vitamine B deficiency is the cause of the lesions in pernicious anemia. It has, however, been amply demonstrated that large amounts of liver, administered over long periods of time, will bring about remarkable improvement in the symptoms and signs referable to the lesions in the nervous system in pernicious anemia.

CONCLUSION

Forty-four cases of pernicious anemia, in which there were symptoms referable to changes in the central nervous system, have been treated by liver or a combination of liver and liver extract.

Of twenty-three cases followed for more than six months, improvement in symptoms and signs has occurred in 55.17 per cent. In twenty-one cases treated for less than six months, improvement was noticed in only 31.25 per cent. In eight cases of outspoken combined degeneration, treated for more than ten months, there was improvement of symptoms and signs in 58.9 per cent.

It is essential that large quantities of liver, or liver and liver extract, be employed over long periods of time.

When the amount of liver is much reduced, or dispensed with, relapses may occur promptly.

It seems probable that in pernicious anemia the myelin degeneration may occur in the peripheral nerves and brain, as well as in the spinal cord, and that some of the symptoms and signs which undergo improvement are referable to a peripheral neuritis.

THE TREATMENT OF PSORIASIS VULGARIS WITH INTRAVENOUS ADMINISTRATION OF ACRIFLAVINE*

SAMUEL E. SWEITZER, M.D., and PHILIP K. ALLEN, M.D.
Minneapolis

IN 1928 Professor M. Oppenheim of Vienna reported the successful treatment of psoriasis with intravenous injections of trypaflavine combined with ultraviolet irradiation. Injections of this dye, an aniline derivative (acriflavine hydrochloride), were shown to have a strong photosensitizing effect, and were given as a means of increasing the value of the actinic rays.

The following year through the courtesy of Dr. J. S. Biehn of the Abbott Laboratories we were furnished with a purified neutral acriflavine suitable for intravenous use. Later, because of the toxicity of the neutral salt, this was replaced by an acid acriflavine.

Twenty patients were selected for treatment from the out-patient departments of the Minneapolis General and the University Hospitals. All were unquestionable cases of psoriasis of the subacute or chronic type. Most of the patients had already been under our observation for some time, and all had received other therapeutic measures in the past. The series included twelve males and eight females between the ages of eighteen and fifty-seven years.

A preliminary series of seven patients received intravenous injections of the first preparation, the neutral salt. In each case the administration was followed by a reaction, the mildest of which consisted of marked flushing, with a sensation of heat in the skin and considerable nausea. In other patients there was severe nausea with emesis. Three individuals who were able to continue treatment showed no improvement after the fourth injection and the treatments were discontinued. The acid acriflavine was supplied several months later. This new preparation, given to three patients of the first series, was found to produce no ill effects. The number of patients was then increased to twenty. It was found that the use of a concentrated solution occasionally caused venous thrombosis. In two instances there was nausea when the solution was injected too rapidly.

The acriflavine was supplied in ampules of 0.1 gram each. The contents of one ampule were dissolved in 20 c.c. of sterile distilled water and injected slowly. With this method 0.1 gram doses of the drug were given three times weekly and were well borne in every instance. Early in the series no ultraviolet therapy was used in conjunction with the treatment. Later, in cases which did not respond and in those in which improvement had come to a standstill, injections were followed by suberythema exposures to the alpine lamp. In all cases throughout the treatment an ointment containing three per cent salicylic acid and six per cent sulphur in vaseline was applied to the lesions daily.

While several cases showed little or no improvement, the majority were benefited and in four the results were striking. Case 2 had for years been incapacitated from work because of the severe involvement of his hands and finger nails. He had been under our observation for two years, the condition having been intractable to other types of therapy. Although the last vestiges of the eruption did not entirely disappear, he improved rapidly and was soon able to resume manual work. Cases 4 and 14, both women, gave a similar history of resistance to other forms of treatment. Their eruptions disappeared entirely by the ninth and tenth injection respectively and at the present time, after an interval of three months, there has been no recurrence.

It was noted that the nummular type of lesion responded best to this form of therapy. In our series the results in the females were better than in the males, the best response being seen in the females with the nummular type of psoriasis.

Involution of the psoriatic lesions under treatment followed a definite course. There was a gradual flattening of the papules and a diminution of the scales leaving a pigmented area in the patch formerly involved. This pigmentation faded slowly and was the last evidence of the eruption to disappear. A majority of the cases

CASES TREATED

Case	Age	Sex	Type	Location	Duration	Injections	Lamp	Results
1	31	F	Circinate and Guttate	Profuse eruption, trunk and extremities	12 yrs	8	None	No improvement, refused further treatments.
2	42	M	Diffuse and Nummular	Very profuse generalized eruption	24 yrs	24	After 15th Injection	Excellent. Eruption disappeared with exception of isolated papules.
3	57	M	Diffuse and Nummular	Trunk and extremities	10 yrs	15	After 10th Injection	Moderate improvement. Many lesions still present, although greatly faded.
4	38	F	Nummular	Elbows and knees	4 yrs	9	None	Eruption entirely disappeared in three weeks.
5	35	M	Nummular	Profuse, trunk and extremities	18 yrs	20	After 15th Injection	Much improved. Pigmented areas remaining with isolated papules.
6	40	M	Diffuse	Trunk and extremities	2 yrs	24	After 20th Injection	Much improved. Only few small areas remaining.
7	55	F	Nummular	Extremities	7 yrs	14	None	Eruption entirely cleared. Slight recurrence 6 weeks later.
8	20	M	Nummular and Guttate	Hands, arms and genitalia	3 yrs	24	After 6th Injection	No improvement. Exacerbation three weeks after discontinuing treatments.
9	22	M	Guttate and Diffuse	Extremities	2 yrs	18	None	Slight improvement.
10	43	M	Guttate and Nummular	Trunk and extremities	10 yrs	12	None	Marked improvement. Pigmentation with few isolated punctate lesions remaining.
11	31	M	Nummular	Profuse eruption of trunk and extremities and scalp	12 yrs	24	After 18th Injection	Very little improvement. Slight fading of existing lesions.
12	35	M	Nummular and Diffuse	Very profuse eruption, face trunk and hands	20 yrs	24	After 18th Injection	No improvement.
13	18	M	Guttate and Diffuse	Trunk and extremities	5 yrs	15	None	Moderate improvement. Many lesions disappeared. Those remaining greatly faded.
14	46	F	Nummular	Trunk and extremities	9 yrs	10	None	Entirely free from eruption.
15	38	M	Guttate and Diffuse	Profuse eruption, scalp, trunk and extremities	4 yrs	18	None	Moderate improvement. Many lesions disappeared; others unchanged.
16	35	M	Nummular and Diffuse	Scalp and extremities	3 yrs	18	After 15th Injection	No improvement.
17	42	F	Nummular and Guttate	Extremities	17 yrs	15	None	Many lesions disappeared. Others faded.
18	21	F	Guttate and Diffuse	Profuse eruption, scalp, face, trunk, and extremities	6 yrs	18	After 12th Injection	Very little improvement. Itching, which had been marked, relieved with first injection.
19	32	F	Guttate	Profuse eruption, face, trunk and extremities	2 yrs	12	None	Moderate improvement.
20	37	F	Guttate and Diffuse.	Profuse eruption, trunk and extremities	16 yrs	15	None	Marked improvement, although numerous lesions remained.

Fig. 1. Case Number 14 at the beginning of treatment.

Fig. 2. After six treatments. Note residual pigmentation with isolated papules.

Fig. 3. After nine treatments.

Fig. 4. One month after the last injection. Ten injections were given.

showed improvement without complete disappearance of the lesions. In these, improvement continued for a variable time and then remained stationary, leaving at the site of the psoriasis patch a pigmented area containing a few isolated, scaly papules.

In none of the cases in which the eruption disappeared entirely was violet ray used. It was further noted that lesions on the protected areas of the body showed involution as rapidly as those of the hands and arms, which were more exposed to actinic rays. Throughout the series the patients who showed improvement did so without the rays, although the addition of actinic therapy undoubtedly enhanced the value of the treatment. In three cases which showed no improvement with injections, the addition of radiation produced no beneficial results.

Obviously, then, improvement in these cases was not due entirely to the photosensitizing action of the drug. The antiseptic action of this and related dyes has long been known and successfully utilized in the treatment of other conditions. Whether it is this or some other property of the drug which is responsible for the therapeutic results is a matter for speculation.

While our results as a whole were pleasing, we do not wish to create the impression that we consider this drug as a "cure-all" for psoriasis or a specific in any sense. Equally good or better results have been reported with various preparations. It has long been known of this resistant disease that some cases will respond to one type of treatment while others require quite a different form of therapy. We recommend intravenous use of acriflavine, therefore, only as a practicable addition to the medicinal armamentarium in the treatment of psoriasis.

SUMMARY

1. Twenty cases of psoriasis vulgaris treated with intravenous injections of acriflavine are reported.

2. All but three cases of the series showed clinical improvement and in four cases the results were striking.

3. The therapeutic results cannot be entirely attributed to photosensitization.

4. Intravenous administration of acriflavine is of practical value in the therapeusis of psoriasis.

THE TESTIMONIAL INDUSTRY

Two or three years ago certain members of the medical profession were asked to answer a question that they were wholly incompetent to answer. The question was whether, in their judgment, the "toasting" process alleged to be applied to the tobacco in "Lucky Strike Cigarettes" was likely to free the cigarettes from irritation to the throat. In addition to the questionnaire, the doctors received a carton of 100 cigarettes. The Lucky Strike people now claim that over 18,000 physicians answered the question given in the affirmative. Today physicians in the south and possibly other sections of the country are being circularized by the concern which exploits "Ironized Yeast." "Ironized Yeast" belongs to the get-plump-quick class of nostrums. It is a mixture of yeast and iron. It also contains phenolphthalein. The circular letter that the Ironized Yeast Company is ending out to physicians starts out with this rather crude offer: "A GIFT WORTH $10 FOR YOU FOR JUST A LITTLE INFORMATION." The physicians are then asked to answer two questions, the answers evidently to be used in the exploitation of Ironized Yeast. For the answers written on his own stationery, the physician is offered "a luxurious flacon of exquisite French perfume—TOUT PARIS DE GUIMET regularly sold at $10." Will the medical profession bite? (Jour. A. M. A., August 30, 1930, p. 679.)

EXTRA-UTERINE PREGNANCY: ANTECEDENT AND SUBSEQUENT HISTORIES IN 471 CASES*

James C. Masson, M.B. (Tor.)
Rochester, Minnesota

THE possibility of extra-uterine pregnancy must often be considered in the examination of women as a routine during the child-bearing period. Some such patients never have the alarming symptoms listed in textbooks, and they recover spontaneously if complete tubal abortion occurs during the early weeks of pregnancy. The ovum dies, the bleeding stops soon after the tube is emptied, and the resulting hematocele and fetal structures are absorbed, leaving little, if any, pathologic evidence. The same result occasionally follows rupture of a tube between the folds of the broad ligaments, with production of an intraligamentous hematoma and death of the ovum. Such patients experience severe pelvic pain, marked local tenderness, definite tumor on the side of the rupture, and more or less shock. However, if bleeding stops, the patients recover. Every lithopedion represents an ectopic pregnancy that has progressed past the fourth month and in which the fetus has died. In such cases, however, the condition has not been recognized until at operation months or years afterward. Masson and Simon in 1928 reported nine cases in which lithopedions were observed at The Mayo Clinic in a study of 445 cases of extra-uterine pregnancy.

Statistics on the incidence of tubal pregnancy vary a great deal. From some clinics, an incidence as high as one in 150 normal uterine pregnancies is reported, whereas from others the ratio is reported as one extra-uterine pregnancy to more than 300 normal pregnancies.

Fecundation probably occurs normally in the outer part of a fallopian tube, and the fertilized ovum is propelled by the musculature of the tube and the ciliated epithelium into the uterine cavity, where, under normal conditions, it becomes attached and develops during the following forty weeks. If for any reason the passage of the ovum along the tube is interrupted, and it becomes embedded in the tubal mucosa and commences to develop, extra-uterine pregnancy results. It is Kline's belief that more or less decidual reaction occurs at the site of implantation. Williams believes that the main purpose of the decidua is to protect the maternal tissue against invasion by the trophoblastic cells. Hemorrhage depends on the inability of the relatively scant decidua in the cases of tubal pregnancy to prevent invasion of the musculature and blood vessels.

Polak mentioned three types of ectopic pregnancy: (1) that in the free end of the fallopian tube (76 per cent); (2) that in the isthmic portion of the tube (21 per cent), and (3) that in the intramural or interstitial part of the tube (3 per cent). The possibility of the occurrence of ovarian pregnancy must be admitted, since cases have been reported. One case of abdominal pregnancy, with placental attachment to the under surface of the liver and the transverse colon, was referred to by Williamson. I believe, however, that it may be inferred safely that all cases of extra-uterine pregnancy are primarily tubal, and that the placental attachment elsewhere is secondary.

The etiologic factors predisposing to the production of tubal pregnancy are: (1) previous inflammatory condition in the tubes; (2) previous inflammatory condition in other pelvic or abdominal organs; (3) previous operations; (4) congenital anomalies affecting the tubes, such as points of stenosis and diverticula, and (5) kinking or partial obstruction of the tubes as the result of malposition of the uterus or as the result of pelvic tumors. Moreover, the possibility of tests for sterility predisposing to the condition has been suggested by some authors.

The early diagnosis of tubal pregnancy is always difficult. As has been stated, in cases in which early death of the ovum occurs the symptoms are mild and of such short duration that a diagnosis is not made. On the other hand, the symptoms may be those of an acute abdominal lesion associated with extreme pain and tenderness in the pelvis, more marked on one side, or of severe internal hemorrhage, general shock, and slight or moderate vaginal bleeding. In most cases the history indicates a condition between

*From the Division of Surgery, The Mayo Clinic, Rochester, Minn. Read before the Minnesota State Medical Association, Duluth, Minn., July 14 to 16, 1930.

these two extremes. The degree of pain is in direct proportion to the amount and rapidity of dilatation of the tube, or to the tearing apart of the fold of the broad ligament as the result of tubal rupture and of hemorrhage between the folds of the broad ligament. Weakness, dyspnea, fainting, shock, and collapse are dependent on the amount and rapidity of intra-abdominal hemorrhage. The amount and frequency of vaginal bleeding vary a great deal in different cases, but are never excessive. Kline stated that vaginal bleeding is not caused by separation of uterine decidua, and that in many cases such a structure does not develop. Curtis expressed the belief that decidua exists as long as the fetus is alive and it disappears after the fetus dies. Polak and Wolfe expressed the belief that vaginal bleeding continues as long as the ovum is alive and has any attachment to the tube. Such bleeding is from the uterus and not from the affected tube. Free uterine bleeding always means something other than tubal pregnancy; it generally means abortion. The association of intra-uterine and extra-uterine pregnancy, with symptoms of threatened abortion, should be suspected in such cases. Stein reported thirty-six cases observed since 1913. The temperature, as a rule, is only slightly elevated. The leukocyte count frequently changes; Farrar and Hendry believe it to be an index to the amount of free blood in the peritoneal cavity. The larger the amount of free blood, the higher the polymorphonuclear leukocyte count. The data obtained on bimanual pelvic examination naturally are dependent on the pathologic condition, and on the site of the abnormally situated products of conception. The possibility of the condition being bilateral must be considered. Johnson and Diasio reviewed ten cases from the literature published during the last seven years and added one of their own. The amount of bleeding that has occurred, and whether it has been between the folds of the broad ligaments or free into the pelvic cavity, naturally will affect the changes found. Also, whether the bleeding has been frequent in small amounts, with time for walling in, or whether it has been copious, and of recent occurrence, will modify the symptoms and signs. Insertion of a needle into the culdesac, or vaginal puncture, is often practiced by certain gynecologists, but the method is not without danger.

As a rule, there is nothing suggestive in the history of the case until after the first month of pregnancy. The patient may then be suspicious that she is pregnant. Later, on account of colic-like pelvic pain and irregular vaginal bleeding, she seeks medical advice. In many cases the early symptoms are much more alarming, the terrific pain and free intra-abdominal bleeding making emergency treatment advisable.

I believe that abdominal section, with removal of the affected tube and control of hemorrhage, is advisable in all cases as soon as the diagnosis is made, provided the patient is in a well-organized hospital where a satisfactory and safe anesthetic can be given and where a solution of gum acacia can be given intravenously, or a transfusion of whole blood, properly tested. The preferable method of anesthesia in critical cases is local anesthesia with ethylene by inhalation. I have never resorted to autotransfusion, but in the absence of gum acacia or a suitable donor, it would be advisable. There is no doubt that many patients who are in collapse immediately following severe hemorrhage will improve if treated expectantly, but there is no assurance that they will improve; many do not, and every minute of delay adds to the danger. Two patients in the series to be reported here were admitted in extremis and died of hemorrhage without operation. Vaginal section is advised in some cases of tubal pregnancy, but under modern technic I believe that abdominal section is to be preferred in all cases.

If the patient is in good condition, an operation is a relatively safe procedure and satisfactory results will be obtained in a high percentage of cases. On the other hand, if there has been excessive intra-abdominal bleeding, if there is superimposed infection, or if the ovum has survived the tubal abortion or tubal rupture and has advanced to the stage of abdominal pregnancy, the operation may be one of great risk. In cases of abdominal pregnancy, there will be decidedly less risk to the mother if the operation is delayed until well after the time of expected confinement and death of the fetus, since the blood supply will be much reduced and the fetal structures can be removed without risk of severe hemorrhage. If the patient can be cared for by an experienced surgeon in a well-equipped hospital, operation should be performed promptly in an

endeavor to save the child, even though many such children are crippled or deformed.

In a previous paper on extra-uterine pregnancy and subsequent pregnancies, results in 198 cases were reported. Eighty-seven (44 per cent) of the 198 patients became pregnant after having had an extra-uterine pregnancy. In all, the number of pregnancies subsequent to extra-uterine pregnancy was 162, and in 111 of these the pregnancies were normal. In thirty-four cases (20 per cent of the 162) the pregnancies were intra-uterine but terminated in miscarriages. Eighteen (less than 12 per cent of the 162 pregnancies) were extra-uterine. Therefore I believe that bilateral salpingectomy is not a justifiable operation for extra-uterine pregnancy if the opposite tube is apparently fairly normal.

From January 1, 1903, to December 31, 1928, 471 patients with 486 extra-uterine pregnancies were treated at The Mayo Clinic; 168 of these patients were reported on in 1914 by Mussey. The youngest patient was aged fifteen years, and the oldest was aged fifty-two years. The average age for the patients was thirty-one and seven-tenths years. In twenty cases the ovum was still developing in the tube when operation was performed. From the operative description, it was often impossible to determine whether tubal abortion or tubal rupture had occurred, but there were probably at least twice as many cases of tubal abortion as of the more serious complication of rupture.

There were seven cases of abdominal pregnancy, in three of which the pregnancy had reached full term. In one case an apparently normal child was delivered, but died suddenly about seventy-two hours later. In another case, a deformed child was delivered who died about two hours after birth. In the third case, the fetus, which was macerated and had reached full term, was dead and probably had been dead for about six weeks. It was possible to remove the placenta and greater part of the membranes in each case; the mothers all recovered uneventfully. In the other four cases of abdominal pregnancy the fetuses were alive and were between four and five months old. Lithopedions were found in ten cases. There were three cases of bilateral tubal pregnancy and one case in which a twin pregnancy existed in one tube. Cases of associated intra-uterine and ectopic pregnancy were not found.

The average length of married life for the group was eight and nine-tenths years. Previous sterility and previous abnormal pregnancy stressed by Allen are important etiologic factors. In this series, 109 (23.14 per cent) did not give a history of previous uterine pregnancy and fifty-three (11.25 per cent) gave a history of having had only miscarriages or ectopic pregnancies.

A history of previous pelvic disease was obtained in 221 (46.9 per cent) of the cases. The average length of time from the last menstrual period to the onset of symptoms was ten and sixty-two hundredths weeks. Pain was the chief complaint in 278 (62.32 per cent) of the cases. In 160 (36.03 per cent) vaginal bleeding was the chief complaint but it occurred in others as well; namely in 375 cases (79.61 per cent of the total number). The average blood pressure in millimeters of mercury was systolic 118.56, and diastolic 82.61. The average pulse rate was 90.5 beats each minute, the average temperature 98.84° F., the average hemoglobin 66.41 per cent, and the average leukocyte count 9,080 in each cubic millimeter of blood. There were six deaths following operation, an operative mortality of 1.27 per cent. Two other patients were admitted in extremis and died from hemorrhage without being operated on.

In two cases in this series, early tubal abortion was found accidentally at necropsy; one patient had died of acute nephritis, and the other of carcinoma of the esophagus.

PHYSIOLOGICAL RESPONSE OF GUINEA PIGS TO ETHYLENE DICHLORIDE VAPOR

The United States Public Health Service, in coöperation with the Bureau of Mines, has conducted certain investigations relating to the effect of the several gases used in household refrigerators. Such investigations relating to ethylene dichloride vapor are of interest. The acute physiological response of guinea pigs exposed to air containing ethylene dichloride vapors was determined. The concentrations of vapor and periods of exposure ranged from those which produced death in a few minutes to those that caused no apparent effect after several hours. The symptoms, gross pathology, and fatality are given, together with a brief discussion of potential health hazards.

1. In the order of occurrence, the symptoms produced in guinea pigs by inhalation of ethylene dichloride vapor are eye and nose irritation, vertigo, static and motor ataxia, retching movements, semi-consciousness and unconsciousness accompanied by uncoördinated movements of the extremities, and death if exposure is continued. Exposure to 6 per cent vapors causes all these symptoms, excepting death, to occur in less than 10 minutes, and death in about 30 minutes. Exposure to 1 per cent causes all the symptoms to appear in 25 minutes with the possibility of death occurring a day or more following an exposure of about 15 to 20 minutes. Exposure to 0.12 per cent did not cause apparent symptoms or death following an exposure of eight hours.

2. The gross pathological findings were hyperemia, congestion and edema of the lungs with secondary degenerative changes in the kidneys. The severity of the pathology increased with the concentration of vapor and duration of exposure. The lung lesion was the most prominent and probably the greatest causative factor in death. No serious pathology was found for the following concentrations of vapor and periods of exposure: 6 per cent for 5 minutes, 1.7 per cent for 10 minutes, 0.4 per cent for 30 minutes, 0.2 per cent for 120 minutes, and 0.11 per cent for 480 minutes. Also these concentrations and exposures did not cause the death of the animals.

3. The summarized physiological response given in the four degrees usually reported are: 10 to 20 per cent kills in a few minutes; 0.4 to 0.6 per cent, dangerous in 30 to 60 minutes; 0.35 per cent maximum amount for 60 minutes without serious disturbances; 0.1 per cent, slight symptoms after several hours or maximum amount without serious disturbances.

4. A comparison of the results obtained with those reported in the literature for other compounds indicates that for single exposures and periods of an hour or more the toxicity of ethylene dichloride appears to be of about the same order as gasoline, benzene, carbon tetrachloride, and chloroform. For periods of less than an hour it is less toxic than these compounds.

5. The odor of ethylene dichloride is distinct and noticeable, and warning symptoms are produced by relatively safe concentrations.

SURGERY OF THE INFANT ABDOMEN

A. A. Zierold, M.D.†
Minneapolis

IN common usage the term infancy possesses a vague significance, and for the sake of accuracy it will be well to state the basis upon which the following discussion rests.

The newborn enters first into a neonatal period which extends over two or three weeks. This is the time of greatest change and adjustment, in physiology as well as anatomy, and one in which growth and function are almost constantly being brought into new relationships. Immediately following this and extending to the thirteenth or fourteenth month, when the erect posture is assumed, is the period of infancy proper; the period of life that I propose to consider at this time.

The medical treatment of diseases of infancy is upon a sound and rational basis and the pediatrician has assumed his proper position in the field of medicine. Surgery unfortunately has only given reluctant consideration to any modification of its status and in the main treats the child in terms of the fully developed individual.

Surgery of the infant abdomen is quite as distinct a field as is the medical treatment of infant diseases. It is true that the fundamental pathologic conditions are the same at any age; yet the clinical material wherein they are manifested differs greatly. Hence the application of any curative or palliative measures must be made to conform to this variation. Anatomically the newborn is different from the adult, not alone in size but in proportion, and, what is not generally appreciated, this proportion is an ever-changing one. Casual observation notes that the individual's increase in size is not uniform and that he passes through periods of alternative activity and passivity. But this by no means implies that the various body constituents increase uniformly and synchronously, for they do not: they increase with wave-like increment, subject to their physiologic need.

The skeleton of the body, being subject to its functional demands, as a whole increases its measurements in a curve very like that of Figure 1.

The bony framework which supports the abdomen of the infant furnishes a basis for the many variations from the adult, as may be seen in Figure 2.

The cervical, thoracic and lumbar segments of the infant vertebral column occupy respectively one-fourth, one-half and one-fourth of its total length, while in the adult, growth has rearranged the limits to one-sixth for the cervical, one-half for the thoracic and one-third for the lumbar.

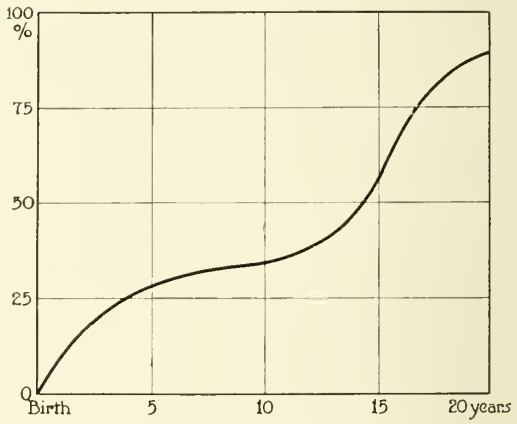

Fig. 1. General growth curve.

Thus it will be seen that in the newborn the longitudinal measurement of the abdomen is relatively much shorter than in the adult. This is made more effective by the absence of the lumbar curve, which appears with the assumption of the erect posture.

The pelvis itself tends to further constrict the abdominal content, as in the infant it is not only more vertical but much shallower and relatively narrower than in the adult. As a result, the abdominal viscera of the newborn must conform to a relatively short axis and a rigid shallow inferior limit.

The upper limit, a more expansile structure made up of the diaphragm and lower rib margin, partially compensates for the constriction by a circumferential increase giving rise to the outward flare of the lower thorax. This, however, is not entirely adequate and the excess bulk of the viscera bulges forward, the abdominal parie-

†Dr. Zierold is Associate Professor of Surgery, University of Minnesota Medical School.

tes giving to the infant the aldermanic proportion which he will only regain in later life.

An examination of the abdominal walls themselves yields definite yet less striking differences

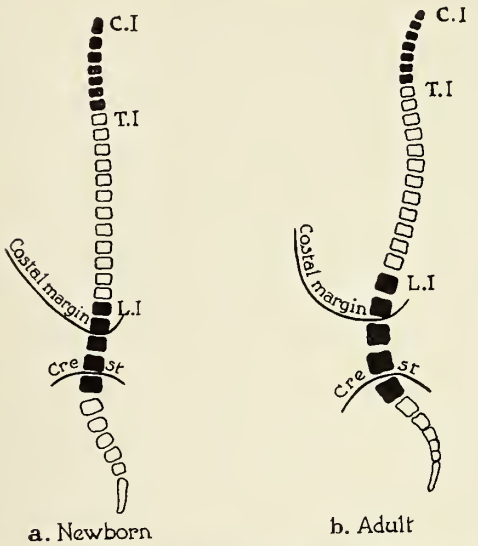

Fig. 2. A comparison of *A* and *B* shows the relatively short lumbar spine in infancy.

than may be found elsewhere. The skin and subcutaneous fat are largely dependent upon the nutritional state and consequently are variable factors. The same is in a measure true of the musculature, which is differentiated to the same degree as in the adult, although proportionately thinner. The fascial development, while nearly proportional to the muscular development, is nevertheless markedly deficient. The aponeuroses of the oblique muscles are thin and delicate and are relatively much less in extent than in the adult. Likewise the anterior and posterior sheaths of the recti are of such fine texture that their constituent fibers can be readily separated. But quite the contrary is true of the peritoneum, which in the newborn is nearly as thick and as strong as in the adult, and on the whole this is perhaps the most noteworthy feature in the parietal structure.

The abdominal viscera at birth present an epitome of fetal life, each an index of its former importance and in total disregard of its future function.

In accordance with this scheme, the liver occupies the greatest space. In fact, in the newborn it occupies two-fifths of the abdominal cavity. As a result it is forced far below the costal margin and a considerable distance to the left, in contact with the spleen. As may be seen in Figure 3 it is relatively much larger than in the adult. The ligamentum teres, so recently a channel for the umbilical blood, is also large, and

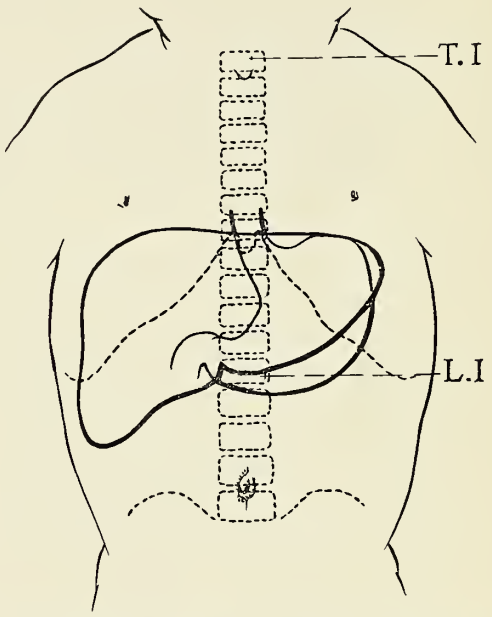

Fig. 3. The skeletal and visceral relations in the infant abdomen.

forms a prominent broad attachment to the anterior abdominal wall.

The spleen in contradistinction to the liver has an apparent rather than real importance, and as regards size alone is more proportional to the adult. Its position in contact with the left lobe of the liver at birth brings it into greater prominence than it occupies in later life. As yet, its ligamentous attachments are only imperfectly vascularized and the vasa efferentia of the adult splenic ligaments are difficult to identify.

The stomach of the newborn is a vertical stomach, but for only a few days, when it becomes transverse, a position which is maintained until the erect posture is assumed. While at birth it is of a few cubic centimeters capacity this rapidly increases during infancy and at one month it has doubled and in a few months more quadrupled. This growth is downward and laterally, the greater curvature escaping under the liver margin and at the same time forcing the spleen to the left and posteriorly.

The levels of the cardia and pylorus are relatively the same in infants and adults, but are both relatively nearer the pelvic brim in the newborn.

The remaining portion of the gastro-intestinal

tract exhibits little of interest except for the cecum. The head of the cecum almost uniformly is found in the right iliac fossa and in the same relative position as in later life, although the relatively large liver and short lumbar segment lend color to the belief that its position changes with postnatal development.

The foregoing brief survey of the grosser visceral differences between infant and adult has been presented not alone to recall mere structural detail but to emphasize what the texts so often neglect, namely, that the newborn is a distinct anatomic entity.

That the infant is a distinct organism to the physiologist is equally true and the biochemical change is no less evident than the structural one. Much of this is inter-related and exhibited as biophysical phenomena. For example, the proportion of mass and surface area is such as to give the newborn a relatively larger area of radiation. This not only modifies the mechanism of heat production, but also its regulation. In close association with this is the fact that the infant has an average water content of 75 to 80 per cent, and requires for growth maintenance about 150 cubic centimeters per kilo per day, which is far in excess of adult needs. From Marriott's observations on the phenomena of anhydremia it is seen that the infant is peculiarly susceptible to disturbances of water balance. The work of Dragstedt and others would suggest that chloride loss may be of equal importance.

Dismissing thus briefly the normal, let us consider for the moment the pathologic processes. Again the infant is unique in that only rarely is the abdomen invaded by bacterial disease processes. The gallbladder and appendix, so commonly affected in later life, are remarkable in this immunity, and peritonitis, when it does occur, is almost invariably primary or due to surgical invasion. As a corollary to this it may be noted that when infection becomes established anywhere in the body of the infant, it more readily overwhelms the patient and bacteremias are more frequent in infancy than adult life; perhaps because of the yet undeveloped immunity. This is in keeping with Hermann's observations and would conform to his idea that peritonitis is an immunity phenomenon. The blood changes are a bit more difficult to evaluate than in the adult. The inversion of the polymorphonuclear and lymphocyte counts and the rapid changes in total counts in the neonatal period tend to diminish the importance of leukocytosis as a diagnostic aid. Nevertheless, if the work of Bakwin-Morris and some others is to be accepted, a leukocyte count above 10,000 in infancy proper is to be considered pathological.

Unfortunately temperature and pulse changes are not so significant and only the very marked variations can be taken as evidence of definite disease processes.

To summarize the pathological considerations the surgery of infancy is for the most part the surgery of obstruction. Of these, hypertrophic pyloric stenosis and intussusception are by far the most common. It is true that there remains a certain number of patients who require operation because of congenital anomies either developmental or in the form of new growths. These, however, require only special technical consideration and are subject to the same general underlying principles which govern the more common operative procedures.

Under ordinary circumstances the infant tolerates operation surprisingly well for short periods. It must be borne in mind, however, that mortality accrues not so much from the magnitude as the duration of the operation. In the adult it is often possible and permissible to be deliberate or even dilatory, but in the newborn there is not that stamina and tenacity to life which allows protracted surgical trauma.

It is obvious that in the early days of life the nutritional state of the patient is always the prime factor in determining his operability. Unfortunately it is not always possible to delay sufficiently to institute proper feeding methods and await a gain in strength and vitality and often we are confronted with a grave surgical condition complicated by starvation and dehydration. To avoid existing or impending dehydration phenomena the ingestion of rather large amounts of fluid under the skin, transfusion into the fontanelle and the intraperitoneal injection of blood or saline are of inestimable value.

It is not my purpose here to dwell upon the rationale of operation but to feature a few points which I believe further a happy termination.

Ether should be the universal choice for anesthesia chiefly because it permits the maximum of effort with a minimum of manipulation. Nothing is so fatal to success as prolonged handling of

already injured tissue. I can see no reason for the extensive mid-line incision so often employed; moreover, infants do not tolerate evisceration nor is the mid-line an advantageous situation for union. Recalling for the moment the topography of the protuberant infant abdomen, the logic of the right rectus incision is at once apparent.

The closure of wounds in adults is generally a matter of relatively little difficulty and may be accomplished by a variety of methods. Not so, however, in the infant. As noted before, the fascia is ill suited to any considerable strain and is surprisingly friable. Because of this and the relatively greater tension exerted (for the infant seems to be striving to break himself open) operative wounds in infants are prone to rupture. And as this is at times a cause of secondary obstruction necessitating reoperation, too much care cannot be employed.

Once off the operating table the patient is out of the surgeon's hands and again becomes a pediatric liability, for it is only inviting disaster to attempt the dual rôle of surgeon and physician. The surgeon may achieve a brilliant operative success but it rests with the pediatrician to conserve it.

In conclusion, rather than attempt a summary of what has gone before, let me reiterate the surgical and anatomical disparity between infant and adult, the necessity for speed and proper medical coöperation. In short, here as elsewhere it behooves us to be accurate, thorough and to be brief.

President's Letter

THE increase in knowledge during the last fifty years has opened an ever multiplying number of avenues from which additional knowledge may be gathered. A practical result is observed in the lengthening number of years young people are required to attend school to fit themselves for their various vocations in life. Especially is this noticeable in the professions and more particularly in the profession of medicine. This vast available knowledge with its practical application has led necessarily to the division of work into many fields. Thus specialism is born.

Medical schools, medical men, medical students and a large and intelligent block of the laity recognize the need of highly scientific men, technical men trained in the field of *research;* the need of thoroughly scientific men trained in the field of *clinical medicine;* and the need for a reduction in time taken to graduate well trained young clinicians, fit to cope with at least 85 per cent of the ills that are encountered in the everyday practice of medicine.

Much intelligent effort is being made to meet these needs. The first is an easy problem to solve; the two latter are more difficult. Johns Hopkins Medical School is an example of the ultra scientific type of school, leaning strongly to the technical training of its students. The University of Pennsylvania Medical School is an example of the type which stresses the teaching of clinical medicine. (Both of these institutions are maintained by private endowment or by the latter together with subscriptions. They are not state supported.)

The tendency in the former type of school is to build its faculty of purely technical men—whose whole time is devoted to the educational interests of the institution. The latter type of medical school endeavors to utilize the knowledge and experience of the practicing physician of recognized skill and teaching ability. His advice and wisdom are sought in formulating and directing the clinical course of study—the clinical curriculum. He is made a member of the faculty and as such enters into the councils of that body. He has something to offer in the training of medical students that the technically and institutionally trained educator does not possess, and therefore cannot give. His active participation in teaching the purely clinical subjects rounds out the purpose of the school. He should have a free hand in conducting the clinical courses and be held responsible for results.

Both of these types of medical education are valuable and both have a definite field of usefulness. Prospective medical students, and their parents, must of necessity be interested in knowing the type of the medical school best suited to meet their needs. Those interested in the study of medicine are often sorely perplexed in choosing a medical school. Too often the choice is determined by such considerations as the size of the institution, its distance from home, the expense, and perhaps other and minor matters. *Primarily the choice should rest upon the ultimate purpose of the student.* Does he wish to become a highly and technically trained medical scientist, tending strongly to and desiring to follow a life of research? Or, does he choose to become a thoroughly trained clinician, practicing medicine among the people, contributing to their relief from suffering and distress, entering intimately into their lives and understanding their problems and needs as only the true physician can, and becoming an active and integral part of the social life of the community in which he lives?

These considerations then should decide him in choosing the type of school in which he will matriculate as a medical student. It should be borne in mind, in making this decision, that but few men and women are by nature adapted to research work. The earnest student, while in his pre-medical course, with the aid and counsel of his instructors (providing these are observant, logical and not too narrow in their outlook), should be able to know his mental and intellectual tendencies pretty well by the time he is ready to enter upon his medical course. He should be able then to decide upon the type of medical school he will attend. The decision is of extreme importance for therefrom the whole course of after life takes direction.

S. H. Boyer

Vol. XIII November, 1930 No. 11

SUPREME COURT OF MINNESOTA UPHOLDS BASIC SCIENCE LAW

On October 10, 1930, the Supreme Court of this State declared the 1927 Basic Science Law constitutional in a splendid opinion written by the Hon. Andrew Holt, Associate Justice. The decision of the Court was unanimous. The rendering of this decision is of tremendous importance, not only to the people of the State of Minnesota, but to the medical profession as well. It is the first time in the history of the United States that the constitutionality of a Basic Science Law has been passed upon by a State Court of last resort. Again Minnesota pioneers in the field of legislation designed to more adequately protect the public health, to raise the standards of the medical profession, to eliminate quackery and to make it possible to more effectively dispose of the quacks who for years have been preying upon the sick.

The Minnesota Basic Science Law was enacted on April 12, 1927. It was passed in the Senate by a vote of sixty-one to two. It was then passed in the House by a vote of one hundred eleven to seven. Thereafter it was re-passed in the Senate by a vote of forty-four to one. The overwhelming vote in favor of the law clearly indicates the wonderful work done by the Minnesota State Medical Association and the Legislative Committee headed by the very able Dr. H. M. Johnson of Dawson. The vote also indicates the broad minded and receptive attitude on the part of the Legislature to enact a law that was extensive in its scope and one that had provisions in it for the enforcement of the law after its enactment. The law is a tribute to the intelligence of the Legislature and we feel that credit should be given where credit is due, particularly in these days of unrest and criticism.

Following the enactment of the Basic Science Law the State Board of Medical Examiners set in motion the machinery provided in the law for its enforcement. The annual registration fee paid in January of each year by every physician and surgeon registered in this state was made available for the enforcement of the various provisions of the law. This money is in the custody of the State Treasury and is expended by the Board as the law requires. The Medical Board has been engaged in a vigorous campaign of prosecuting those who have been practicing healing in the state without lawful right. The Board is also making every effort to make Minnesota as uninviting as possible for quacks in other states. We are certain that the Board has the united support of every member of the medical profession in their efforts. It was this work on the part of the Medical Board in connection with a recent case that precipitated the present decision in the Supreme Court.

The opinion written by Justice Holt clearly indicates that very careful consideration was given

the law and it is interesting to note some of the matters contained in the opinion. Before this is done it might be well to consider some of the objections raised against the law. The first serious objection raised against the law was that the Legislature had no right to authorize the issuance of Basic Science certificates to those lawfully engaged in the practice of healing at the time of the passage of the law. To this the Court said:

"The law is neither arbitrary nor unreasonable in the respect of treating those already licensed as compared with those to be licensed after May 1, 1927."

The Court further said:

"No one can legitimately object to laws raising the standard of knowledge which might aid in the treatment of human ills by those engaged in that calling."

Another contention against the law was that it was unreasonable and arbitrary for the Legislature to classify those engaged in the practice of healing. That is, to make special provision for dentists, nurses, midwives, masseurs and the like. To this contention the Court said:

"Each occupation comes in contact with the human body and may affect its well-being, but none of them relates to what is generally understood as taking charge of persons affected with disease or bodily injury to effect a cure, if we except dentists."

The Court further said:

"With the wisdom of legislative classification, courts are not concerned. In laws of this sort all evils cannot be reached at once, nor every desirable object gained in one legislative session."

We wish to emphasize the significance of the last quotation. It is not possible in this day and age to secure the enactment of every desirable law at one session of the Legislature. Conditions change; new methods of quackery are devised; new cults are formed and laws must necessarily be enacted from time to time to meet these conditions. The Court clearly emphasizes the right of the Legislature to recognize degrees of harm and to proceed step by step and to enact laws that presumably hit the evil where it is most felt.

POLIOMYELITIS IN MINNESOTA

The present epidemic of anterior poliomyelitis began in Nobles County in April and was confined almost wholly to the southwestern part of the state until the latter part of the summer. In August, cases were reported from fourteen additional counties for the most part in the southeastern part of the state. During Septmber the epidemic had further spread, cases being reported in twelve additional counties, and in October, twelve more counties were invaded. The State Health Department gives the following cases reported each month: April—1, May—3, June—16, July—59, August—80, September—100, October (to the 29th)—76. The peak of the curve showing incidence of the disease was reached the first week in August. Instead of the rapid incline usually experienced, this year second and third peaks recurred the first and last weeks in September which were nearly as high as the one in August.

Epidemics have been reported in Illinois, California, and southeastern Wisconsin, and figures show a rather general epidemic throughout the country.

Our worst state epidemic was in 1909 and 1910 when 234 and 201 deaths respectively were reported. In 1916 another epidemic occurred in which there were 912 cases reported with 105 deaths; again in 1921, 705 cases and 102 deaths; and the last epidemic in 1925 with 941 cases reported and 145 deaths. Doubtless the reported cases make up a comparatively small portion of the total cases existing in any epidemic. It is no unusual experience to discover other members of the victim's family ill with fever, headache, sore throat, nausea or vomiting, and perhaps a little neck rigidity and no paralysis, or maybe only a slight paresis or merely an exaggerated reflex which could be readily overlooked. Some have estimated that only about 20 per cent of cases are diagnosed.

This frightful disease which hits like a stroke of lightening here and there and carries a mortality of 11 to 15 per cent, and, what is perhaps worse, leaves its victims ofttimes with extensive paralysis, must however be classed as an infectious disease. The most logical assumption is that a large majority of adults are immune and a certain percentage carriers of the infection. The usual seasonal occurrence of epidemics, the height of the epidemic occurring in August, is difficult to explain. Males predominate among those stricken and the disease occurs more frequently in the first five years of life than in any other five-year period. The mortality rate, however, usually increases with maturity.

The symptoms above mentioned, in the presence of an epidemic should arouse suspicion on

the part of parents and physicians. A frank paralysis leaves no room for doubt. A rigidity of the neck and an increased cell count in the spinal fluid in the presence of an epidemic is sufficient to warrant a diagnosis, isolation, and whatever treatment is possible. There seems to be enough evidence of the value of convalescent serum to warrant its trial. A certain amount of convalescent serum has been available at the University Medical School since September 27. This is obtained by allowing the blood from a convalescent to clot, filtering the serum, and adding a preservative. Twenty c.c. given intramuscularly as soon as a diagnosis is possible, is recommended. The delay to physicians throughout the state incident to sending to the University is costly for the patient. More practical would be the administration of approximately 40 c.c. of blood from a convalescent even though a period of years had intervened since the infection of the donor. Recent experimental work* on this poliomyeliticidal action of normal human serum *in vitro* and the occasional favorable result,† in poliomyelitis with the use of serum from normal non-convalescent adults suggests a practical method worthy of trial.

The use of convalescent serums for wholesale immunization is out of the question.

Physicians should be on the alert to diagnose this disease as early as possible in order at least to establish isolations and quarantine. Although serum treatment cannot be said to have been firmly established, every effort should be made to give it a fair trial.

FOOD FADDISTS

Statisticians have enjoyed the memorable distinction of the superlative in prevarication—"liars, d— liars, and statisticians." In grades of dumbness in like ascent the banner for excellence goes to food faddists. Unfortunately the management of a most worthy milk products firm will not read these lines. Few physicians will hesitate to lend full support.

A recent comment in a magazine states that no one should presume to write an editorial unless he feels and thinks deeply upon the subject treated. Well here goes:* I believe in food—three times a day. I agree with a somewhat obese confrère who says, "Eating is one of our greatest indoor sports." It is possible to even go further: The good old summer time picnic with its ozone, scenery and clutter of indigestibles is far from an affliction, and invites God-given rest to an overwrought brain even though it may clog up a burdened liver.

Need I describe the paid minion assaulting a series of luncheon club groups and culinary assemblies, not to mention our schools, with the absurd statement that everything we are depends upon the food we eat? "Tell me what a man eats for breakfast and I can tell you the reaction he has throughout his day," thunders this oyster. "Look to the cause, gentlemen—if you ever expect to empty our asylums and almshouses, overcome our appalling illiteracy and helpless inefficiency, then learn first to choose your own food and that of your children!"

It is almost a calamity that vitamins have been scientifically exploited, the pseudo-scientific food vender has taken such horrible liberties with them. Man, with his magnificent adaptability to food, can live in almost any part of our known world. Look at the infinite variety in his diet adapted as it must be both to his needs and circumstances. And do not forget how gloriously the much cussed human economy adapts itself to definite poisons, albeit some of these are presently mollified by "toasting" and ultraviolet exposure! Aside from early life it is fair to state that any adults will have a strenuous task evading all needful vitamins in any half reasonable diet. Appetite and food enjoyment—one of our greatest boons in a neurasthenic age—must not be harassed by a flood of senseless taboos and "don'ts." Gourmands and human hippopotami deserve no commendation, but even at that they only hasten to Elysian fields. There they will not be annoyed by the presence of vitamin cranks huckstering cottage cheese and yeast.

E. L. T.

*Written after listening to a professional (Doctor) dairy products exhorter address a luncheon club.

CONSULTATION BUREAU

WM. A. O'BRIEN, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question.*—I have under my care a case which I have diagnosed as complete heart block. The history and cardiac examination are as follows:

Man, married, age 40, farmer by occupation, has always done extremely hard manual labor. Admitted to the hospital with complaint of fainting spells and dizziness. The immediate condition lasted for about 24 hours and grew worse. He stated that he had had these spells in very mild form for the past year and a half to two years. About three days before admission to the hospital he became slightly overheated. He believes that this is the beginning of his condition. Past history was negative.

Pulse rate on admission was 22 per minute. Adrenalin, 10 minims, was given by hypo with marked relief. The cardiac examination showed the pulse rate to be 22, apex beat of the ventricle the same, and that of the auricle about 80 to 85 per minute. The picture showed that of complete heart block, and the patient was given ephedrine, grains 3/8, three or four times a day. This controlled the fainting spells, and the patient was fairly comfortable. Two days following this, continuing with ephedrine, barium chloride, grain ½, was given three times a day. The patient was kept in the hospital three weeks, pulse rate at no time going above 34. Beat was regular in both the auricle and ventricle. The patient improved generally, however, and was able to be up and around without any dyspnea. Atropine in full doses had no effect. The Wassermann was negative. Blood and urine examinations were normal. No foci of infection were found.

At the present time patient is able to do very light exercise with no discomfort, and his condition remains the same as at the time of discharge from the hospital. I would like to get your opinion as to whether or not anything further can be done for this man and as to the prognosis in the case.

Answer.—The following suggestions were received in regard to this case:

(1) From the history and findings there can be no question as to the correct diagnosis in this case, that of complete heart block. The question would be as to the etiology. With syphilis ruled out, it is very likely that coronary disease is at the basis. Because of this it might be well to give the patient metaphyllin, 1/10 gram, dissolved in water four or five times a day. In regard to the specific treatment, I cannot suggest anything further than that already instituted, ephedrine, 3/8 grain, and barium chloride, grain ½. Digitalis is indicated when there is any evidence of decompensation. Apparently this is not present now. Patient is to do only light work, of course. The prognosis is not very good, although I have had cases live quite comfortably for periods of ten years before decompensation set in. I think that the doctor in charge of this case is to be congratulated on his diagnosis and the management of the case.

(2) In the treatment of complete heart block in the presence of Stokes-Adams' phenomenan, we have had our best results in the administration of desiccated thyroid extract. We have very distinct evidence that the cerebral phenomena are not wholly the result of temporary ventricular asystole but may also result from under-ventricular filling and consequent insufficient ventricular outflow. It has been on this basis that thyroid extract has been given, and we have had numerous instances where the manifestations have been entirely controlled, and if not entirely controlled definitely modified. The drug should be given only after the determination of basal metabolic rates with checked readings, and an attempt, of course, should then be made not to produce a therapeutic hyperthyroidism. As a rule, one to two grains daily given in one dose, is sufficient provided the dosage has been accurately standardized and the case observed by occasional basal metabolic rate determinations. The drug may be continued over a rather indefinite period of time. It has no effect whatsoever on the auriculo-ventricular dissociation but it is merely an agent that by increasing the rate of combustion effects some increase in circulation rate. Barium chloride has been used with rather indifferent results, and its action depends upon increasing the irritability of the ventricle, frequently resulting in premature contractions, thereby sometimes increasing ventricular rate.

The general prognosis of complete heart block where the Stokes-Adams' phenomena have occurred is unfavorable. In our series the average expectation of life was about twelve months. Without the Stokes-Adams' phenomena the outlook is considerably more optimistic. The prognosis, however, is chiefly dependent upon the degree of heart muscle capacity, depending to a large extent upon whether or not the fundamental cardiac disease is rapidly progressive or not, and to an appreciable degree on the instituted regime.

(3) It is a clear-cut case of complete heart block which has been very well handled therapeutically. Apparently the Wassermann was negative; but in a case forty years old, I would recommend that the Wassermann be repeated at two different laboratories, making use of both the Kolmer technic and the Kahn technic. Complete heart block due to syphilitic gummatous infiltration, it is true, is fairly rare, but does occur, and in all cases forty years or under I think we should look for it very carefully, because, if it is due to syphilis, treatment directed against syphilis will very frequently clear up the heart block if not administered too late.

2. *Question.*—I have a youngster a week old who has bilateral congenital club feet. I wish you would advise me as to when treatment should be started and of what nature it should be.

Answer.—Correction of congenital club feet should be started in the first few weeks of life. Any simple appliance which will bring the feet in line should be used. A light plaster cast or a cardboard splint can be applied. In any event, the progress of the case should be followed very carefully so that frequent adjustment can be made. In this way it is possible to correct congenital club feet without an operation in most instances.

OF GENERAL INTEREST

Dr. Leon J. Tiber has moved from Saint Paul to Los Angeles, California.

Dr. Joseph Halpin is house physician at the Gillette State Hospital, Saint Paul, this year.

Dr. W. A. O'Brien now gives his health talk over WCCO each Wednesday morning at 11:15.

Dr. F. W. Schacht has left the Mayo Clinic and will practice in Winnetka, Illinois, limiting his practice to urology.

Dr. J. H. White, formerly associated with the Mayo Clinic, will continue practice with the Southwest Clinic, Phoenix, Arizona.

Dr. Charles N. Hensel, St. Paul, is recovering from a fractured leg received September 14 when he was thrown from a horse.

Dr. W. A. Coventry has just returned from a meeting of the American Obstetricians and Gynecologists in Buffalo, New York.

Dr. J. R. Hand, formerly associated with The Mayo Clinic, Rochester, has established offices in the Mayer Building, Portland, Oregon.

Dr. G. D. Guilbert, formerly of Waterville, Minnesota, is Associate Medical Officer at the U. S. Veterans' Hospital at Tucson, Arizona.

Dr. M. G. Gillespie attended the meeting of the American College of Surgeons in Philadelphia in October and was inducted into the College.

Dr. Emanuel Barnett is in private practice at Sanborn, Minnesota. Dr. Barnett was an interne at St. Joseph's Hospital, Saint Paul, the past year.

Dr. Donald De Coursey, who finished his interne work at St. Joseph's Hospital this year, is on the rotating service at the Veterans' Hospital, Minneapolis.

Dr. John A. Haugen is with the Detroit Receiving Hospital, Detroit, Michigan, where he is completing an interneship begun at the Abbott Hospital, Minneapolis.

Dr. Joseph Ryan has become a member of the staff of the Saint Paul Clinic. Dr. Ryan completed an interneship at St. Joseph's Hospital, Saint Paul, this year.

Dr. John Meade is taking a three-qear course in internal medicine at The Mayo Clinic, Rochester, following the completion of interne work at St. Joseph's Hospital, Saint Paul.

Dr. R. E. Hultkrans, secretary of the Chisago-Pine County Medical Society, has left Rush City, Minnesota, and is now associated in practice with Dr. George Dunn, Minneapolis.

Dr. William F. Schoffman is following his interneship at the Abbott Hospital, Minneapolis, with a fellowship in pediatrics under Dr. Frederic Schlutz at the Bobs-Roberts Hospital in Chicago.

Dr. Lloyd H. Ziegler resigned from the staff of the Mayo Clinic, Rochester, Minnesota, August 1, 1930, to accept the professorship of neurology and psychiatry of the Albany Medical College and to be neuro-psychiatrist-in-chief of the Albany Hospital, Albany, New York.

After completing a fellowship in Internal Medicine at the University of Minnesota, Dr. M. J. Shapiro studied at various clinics in Europe and has now returned and is limiting his practice to Internal Medicine with offices at 620 Medical Arts Building, Minneapolis.

The New York Academy of Medicine announces a series of Friday afternoon lectures of special interest to the practitioner, beginning Friday, November 7, 1930, at 4:30 P. M., at the Academy headquarters, Fifth Avenue and 103rd Street. Invitation has been extended to the profession generally.

Dr. James E. Perkins, St. Paul, has been awarded a Rockefeller Foundation Scholarship for a year's study at Johns Hopkins. Since June he has been an assistant in the Minnesota Department of Health and has obtained a year's leave of absence to enable him to pursue his post-graduate study.

Dr. Charles Remy has been selected to succeed Dr. List as superintendent of the Minneapolis General Hospital. After several years in general practice Dr. Remy obtained considerable experience in hospital administration during the World War, having been at the head of a 2,000-bed army hospital in France. After the war he was superintendent of the Yankton State Hospital for the Insane, at Yankton, South Dakota, and before coming to Minneapolis was assistant superintendent of the Michael Reese Hospital, Chicago.

DR. LIST HONORED

On Monday evening, September 29, 1930, a testimonial banquet and reception was given to Dr. and Mrs. Walter E. List at the Hotel Nicollet, Minneapolis, in recognition of the conspicuous service Dr. List has rendered to the city in the upbuilding of The Minneapolis General Hospital.

Some two hundred guests gathered in the Grand Ballroom. The Honorable William F. Kunze, mayor of Minneapolis, presided. The principal address of the evening, entitled "A Minister of Healing," was given by the Reverend Dr. Roy L. Smith. Brief speeches were made by L. N. McWhorter, of the Minneapolis Board of Education, and Paul H. Fesler, superintendent of the University Hospitals.

Dr. Francis E. Harrington, Commissioner of Health,

on behalf of friends and fellow citizens, presented Dr. and Mrs. List with a beautiful silver tea and coffee set.

Dr. Richard Olding Beard, chairman of the Committee on Arrangements, speaking in behalf of the citizens of Minneapolis, presented Dr. List with a Testimonial printed in illuminated colors and bound in a beautiful leather case.

SHORT COURSE IN TUBERCULOSIS

A one-day short course in tuberculosis is to be held at the state sanatorium at Ah-Gwah-Ching, Minnesota, November 6, 1930, in response to requests from physicians throughout the state. The short course is being sponsored by the Minnesota Public Health Association. Dr. H. A. Burns, superintendent of the Ah-Gwah-Ching Sanatorium, will be in charge.

Features on the morning's program include a paper by Dr. W. H. Ude on some phase of roentgenology in relationship to tuberculosis, a paper by Dr. E. K. Geer on "Collapse Therapy," and brief talks by Dr. B. Borreson and Dr. R. R. Hendrickson of the sanatorium staff on "Surgical Tuberculosis" and "The Incidence of Tuberculosis in Cass County," respectively.

During the early afternoon each visiting physician will study the history and make an examination of one patient. All physicians will then meet and discuss the findings. There will also be a question box and any individual problems of the visiting physicians will be discussed at this time.

This short course forms a part of the statewide Christmas Seal work. It is the third to be held at the state sanatorium. Registration is limited and those desiring to attend are urged to communicate with the Minnesota Public Health Association, 11 West Summit Avenue, St. Paul.

INACTIVE DUTY TRAINING SCHOOL, ROCHESTER, MINNESOTA, NOVEMBER 9–23, 1930

The second annual inactive duty training period for medical reserve officers will be held at Rochester, Minnesota, November 9 to 23, under the sponsorship of the Mayo Foundation; directed and personally supervised by instructors of the Medical Corps of the United States Army detailed to Rochester for the purpose. The curriculum embraces basic subjects essential to all medical officers.

The school offers opportunity for officers who have not received summer training to earn one hundred hours toward the required number for promotion at the expiration of their respective periods of appointment. The instruction covers a period of fourteen days of seven hours each. All medical reserve officers are eligible.

Any physician wishing to join the reserve corps should apply at once for a commission and when commissioned will be qualified to register for the course.

The course of instruction is arranged so as to allow visiting officers to attend clinics in the mornings and school of instruction during the afternoons and evenings.

Last year's course proved very profitable. Several officers of various branches of the regular army visited the school.

Medical reserve officers interested should write Colonel Louis B. Wilson, The Mayo Foundation, Rochester, Minnesota.

OBITUARY

M. L. Stiffler
1887-1930

Dr. M. L. Stiffler, who has been in charge of the Saint Paul Child Guidance Clinic for the past six years, died very suddenly on September 7, 1930.

Born at Bedford, Pennsylvania, forty-three years ago, Dr. Stiffler attended Oberlin College for three years and obtained his M.D. from the University of Colorado.

Following the World War, during which he served in the medical corps, Dr. Stiffler was associated with the Veterans Bureau in Minneapolis. When the Child Guidance demonstration was instituted by the Carnegie Foundation at the University, he became associated with that undertaking for two years, and in 1924, when the Saint Paul clinic was established by the Wilder Charities, he assumed charge.

Because of Dr. Stiffler's interest in children, he served as a member of the Boy Scout Council in Saint Paul. He was also a Rotarian and in college joined the Beta Theta Pi fraternity.

Dr. Stiffler died the day before the opening of the Minnesota Conference of Social Work in which he was to have taken part. He is survived by his widow, a daughter Suzanne, aged 11, and a son Charles, aged 7.

John A. Lyng
1864-1930

IN MEMORIAM

On September 27, 1930, when at his home in Minneapolis Doctor John A. Lyng was suddenly stricken dead. A good colleague and a man of more than ordinary ability was thereby removed from our profession and the ranks of organized medicine. It was the good fortune of the writer to have known our deceased colleague for many years, and in appreciation of his long friendship these obituary remarks are therefore given a more personal coloring.

Dr. John A. Lyng was born in the city of Namsos, Norway, December 25, 1864, the youngest of several sons born to a cultured and well favored family; he was educated in the schools of Norway in keeping with the ideals and cultured traditions of his family.

In the latter eighties of the past century he came to the United States of America and took up his residence in Minneapolis, where a brother of his owned and conducted a drug store. While there he entered the University of Minnesota and was graduated from its medical department in 1890, since which time he has practiced his profession in Minnesota.

Rather early he evidenced a preference for surgery

because his first appointment was that of surgeon for the Soo Railway Company. Next we find him giving his adopted country the benefit of his services during the Spanish-American War as an officer in the United States Army medical corps in Cuba.

At the conclusion of this war he returned to Minnesota and now established a successful medical practice at Alexandria and later at Fergus Falls, in both places gaining an enviable reputation as a conscientious physician and a skillful surgeon. For the last twelve years he again made Minneapolis his home, and was buried there October 1, 1930, in Lakewood cemetery, his mortal remains being escorted to their last resting place by a large throng of professional and masonic friends.

Dr. Lyng was a loyal member of our profession, continuing his membership from the Park Region Medical Society over into Hennepin County Medical Society, Minnesota State Medical Society and American Medical Association; he was also a charter member of the Thulanian Club of the University of Minnesota and a member of the Veterans of Foreign Wars.

He is survived by his wife, Else Froedtert, from Milwaukee, Wisconsin, and his son John; also a brother living in Norway and a number of more distant relatives.

From his many travels both in this country and abroad as well as from his constant studies, he remained a true scientific student all his life. Dr. Lyng had developed into a capable and sound surgeon and when he moved back to Minneapolis as before stated, it was undoubtedly with the plan and ambition of building up a surgical practice in our metropolitan sister city, and this goal not having been reached can safely be attributed to the change that took place in his health, and for a number of years caused his invalidism. A coronary arteriosclerosis with a myocardial lesion, quite often manifesting itself through very painful attacks of angina pectoris not only brought about this change in his professional career but also finished his earthly labors in the sudden manner above mentioned. And thus we mourn the loss of a proficient, upright colleague and a fellow citizen, who was rich in the profession of a strong character and a mind unafraid. "Requiescat in pace."

E. Klaveness, M.D.

George S. Davis

1845-1930

Mr. George S. Davis of the firm of Parke, Davis and Company, following a considerable period of poor health, died recently at the age of eighty-five.

A native of Detroit, Michigan, he began his career as a clerk in a retail drug store. Later he went into the wholesale drug business and in 1867 became associated with the pharmaceutical manufacturing concern of Duffield, Parke and Company. In 1871, Mr. Duffield retired and the present firm name of Parke, Davis and Company was adopted. Mr. Parke retired from active business over thirty years ago.

George S. Davis showed unusual ability in discovering, developing and organizing men, which was a big factor in the rapid expansion of his business concern. His original methods were largely responsible for the dawn of a new era in supplying the pharmaceutical needs of the medical profession.

QUEENE ELIZABETH'S MEDICINE FOR A COLDE

The following prescription apparently devised or recommended by Queen Elizabeth is taken from "A Booke of Phisicke, Surgery, Preserves and Cookery, with Sondry Other Excellent Receipts," printed about 1615.

"Take a quart of newe milke, put into it 2 sponefulls of honey, 4 ounces of linseede, and as it boyles put in peeces of scarlett or redd cloth and laye one peece on your stomack and one opposite to that on the backe, and soe goe to bedd: sweat and you shalbe well."

Despite inferences to the contrary that might be drawn from the title, the volume referred to is confined entirely to medicine and contains a very extensive and interesting collection of medical recipes including "An oyntment to anoynt the side in a Plurisy, A Sirrup for the Lungs, A purgation against Melancholly, A Remedy for them that have sore Eys, For one that cannot brooke his meat nor digest it, To help a Sciatica, &c."—*Health News,* Sept. 1, 1930.

BLACKTONGUE PREVENTIVE VALUE OF LARD, SALT PORK, DRIED GREEN PEAS, AND CANNED HADDOCK

For several years the Public Health Service has been conducting studies relating to nutritional diseases with particular reference to pellagra. A report recently made public indicates that the blacktongue preventive potency of lard, salt pork, dried green peas, and canned haddock has been studied. The results show that lard and salt pork are poor sources of the blacktongue preventive. Canned haddock contains the blacktongue preventive factor and, when used in relatively large proportion, the clinical manifestations of blacktongue are prevented. Dried green peas contain the blacktongue preventive but in relatively small amount. Fifty per cent or more of the test animals on the lard, salt pork and haddock diets showed post-mortem evidence of fatty degeneration of the liver.

METHODS OF FAVORING BILE DRAINAGE

Proprietary mixtures containing phenolphthalein, bine the experimentally demonstrated stimulants to bile secretion (salicylic acid and menthol) with the bile exinadequate) and the laxative action of phenolphthalein. The Karlsbad treatment, consisting of the ingestion of vogue some years ago. This was an attempt to comhot alkaline laxative mineral waters, is another way of aiming at the same result, which has centuries of favorable experience in its favor. Either the natural or the artificial Karlsbad salt (N.F.) may be taken by the teaspoonful to a tumblerful of hot water half an hour before the larger meals. (Jour. A. M. A., June 7, 1930, p. 1861.)

A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION

IMMUNIZATION AGAINST DIPHTHERIA

Vaccination has been accepted the world over in combating smallpox, in spite of the fact that at least every seven years the vaccination must be repeated. Immunization against diphtheria has been even more successful, because in all but exceptional cases, only a single series of inoculations is necessary. Established immunity, as proved by a negative Schick test, protects the subject for life.

In the past, most of the work in immunization has been done on the school child; children of the preschool age have been neglected to a considerable degree. Inasmuch as the passive immunity with which children are born persists about four to six months, it is evident that if all children are to be protected the immunzation against diphtheria must be carried out in the first year of life; the period of preference is from the sixth to the twelfth month. At this age the child can be inoculated with little discomfort and with few of the severe reactions that are occasionally observed in older children and adults.

The material of choice for this immunization is the modified toxin—the so-called toxoid or anatoxin. This does not require the use of antitoxin, which, in some cases at least, seems to have rendered the child susceptible to a serious reaction from later serum injections. The results have been so uniformly good, and the severe reactions in the first few years of life have been so conspicuously absent, that in this period the use of toxoid is preferable to the use of toxin-antitoxin. For older children to prevent severe reaction a preliminary test may be necessary before toxoid is used; or instead of a toxin, a toxoid combined with antitoxin made with sheep serum rather than with horse serum may be used.

Six months after the inoculation it is necessary that a Schick test be done to determine immunity, since there are a few children in each 100 who are not immune. From 95 to 98 per cent of children who are inoculated are rendered immune.

The medical profession and all public health workers are solidly behind the campaign to eradicate diphtheria, and every physician should consider it his duty to see that all children under his charge are immunized against diphtheria.

Henry F. Helmholz, M.D.

An illustrious group of names shines forth in the history of the conquest of diphtheria. We have a complete armamentarium for the eradication of this disease in civilized nations. Its virulence can be determined. Usually its lesions are easily recognized and, if not, a twenty-four hour pause for laboratory examination reveals the invader. Carriers can be identified. By the Schick test susceptibles can be isolated. The disease is so curable that it is more or less of a disgrace to lose a case. And, finally, the prevention has long been possible with the use of toxin-antitoxin. Even this has been improved and the use of toxoid makes the immunization much more definite and more easily accomplished.

It seems, however, that the medical profession of our own State has let down a little in the spreading of the propaganda of diphtheria immunization. In isolated communities a larger percentage of the children have been immunized, but the percentage throughout the State is not so great as might be desired. The material is furnished by the state. A moderate fee for doing this work is fair. If we fail to advocate and do this work, and for a moderate charge, the State will do it free. Here is one disease about which we know much and which can be prevented.

MISCELLANEOUS

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

UNLICENSED DOCTOR ENTERS PLEA OF GUILTY

State of Minn. *vs.* Dufort

On October 9, 1930, J. E. Dufort of Northome, Minnesota, entered a plea of guilty before the Honorable Judge Wright of International Falls. The defendant was charged with practicing medicine without a license. Dufort has been located at Northome for the past twenty years and has never possessed a license to practice medicine in this state or elsewhere. He was arrested in 1928, charged with violating the Basic Science Law. He continued to violate the law with the result that in June 1930, he was again arrested for the same offense. The Court sentenced Dufort to a term of one year in the county jail and to pay a fine of one hundred dollars. The Court suspended the sentence on the following conditions:

1. The defendant must leave the county.
2. The defendant must refrain from practicing healing in any way, shape or manner irrespective of whether a fee is charged or not.
3. The defendant must not be charged with violation of any other statute of this state.
4. The defendant must report once every ninety days in writing to the Judge of the District Court, giving his occupation and present place of residence.

Dufort was very fortunate in escaping a jail sentence because of his previous good fortune before the Court. A number of citizens from Northome interceded for Dufort but they were warned by the Court not to interfere in this matter again. The defendant was not licensed and apparently had no chance of getting a license and will be placed in the county jail for the slightest infraction of the law. The matter was handled by Mr. Brist on behalf of the State Board of Medical Examiners.

MEDICAL ETHICS

Apropos our recent editorial on Physicians and Advertising which appeared in the October number of MINNESOTA MEDICINE, we are reproducing a letter written by the Chairman of the Publicity and Education Committee of the Hennepin County Medical Society to the Minneapolis Journal in reply to a number of editorials which have recently appeared in that newspaper. Most physicians, we feel sure, have never read the Code of Ethics which embodies the printed rules of conduct for physicians adopted by our national association. The universal rules of gentlemanly behavior which include the Golden Rule, along with local convention as to professional procedures, are sufficient for most of us. On the other hand, the presentation of the accepted Code of Ethics to new members of County Medical Societies as practiced by the Hennepin County Medical Society would be well imitated by all county organizations.—EDITOR.

To the Editor of The Journal
Minneapolis, Minnesota

Your recent editorials, "The Vagaries of Medical Ethics" and "Why Fight in the Dark," require elucidation and comment, if only because of their utter lack of any specific or constructive criticism or suggestion that might help to remedy what you seem to consider a very unsatisfactory situation.

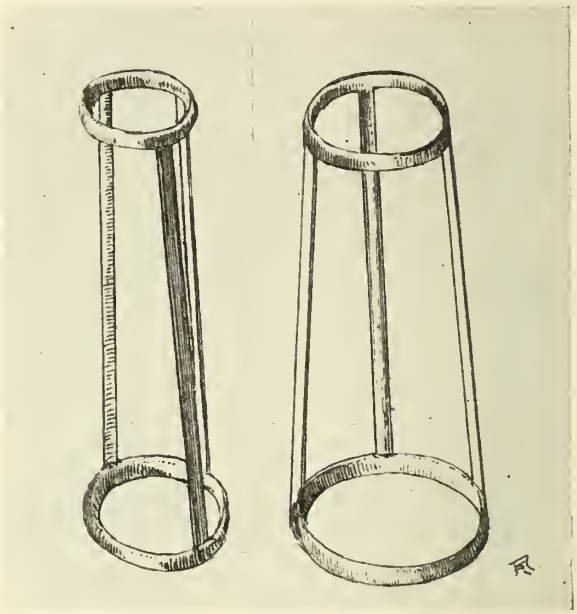
Does it not strike you as somewhat peculiar that that "ancient relic," the medical code of ethics, has been "shot full of holes" every day at least for more than a thousand years, often by much more skillful shooters than even the editor of the Detroit Lakes Record, whom you quote, and still not only survives but thrives, naturally so since it is founded on the principles of a still more ancient relic, the "Golden Rule" which can never die?

Is not your own statement that quacks and charlatans have grown rich by advertising a very illuminating commentary on what would be sure to happen if the section on advertising was expunged from the code of ethics? Would the final result not be merely that the best advertiser and not the best doctor would sell the most medical services? In the final analysis, what has any doctor to advertise unless merely his skill? In this day and age it is not possible for any doctor, working without collaboration, to devise and use alone successfully any method, remedy, or technic which is not certain shortly to become the property of the profession at large. Medicine has ten thousand eyes and it would be a very dishonest doctor, indeed, who advertised the possession of any advantage in these regards.

Possibly there is some doctor whose skill entirely transcends the average. He has some strange intuitive power of diagnosis, some greater penetration in his look, a finer "tactus eruditus" in his finger tips. Possibly he is even the seventh son of a seventh son. But, after all, would not the advertising of such transcendant skill be repulsive to every finer instinct? And who, indeed, is to be the judge of his skill? He may be entirely over-estimating himself, probably is, and there is nothing about which the public is more easily deceived. Some of the doctors who have the largest practices are by no means the most scientific, the most skillful, the most earnestly devoted to the interests of the public itself. Even the fact that a certain doctor has apparently brought about cures where others have failed, is not of itself any certain criterion of his comparative skill.

But who constituted the State Editorial Association as the arbiter of ethics? If the State Medical Association which, by the way, has nothing to do with devising a code of ethics for the medical profession, except by virtue of its influence with, and its membership in, the American Medical Association—feels that it should delegate the revision of the code of ethics to any outside group, why, for instance, should it not choose a group from the Ministerial Association, from

the Civic and Commerce Association or from the Bar Association? Could it not delegate this to any one of these groups with a feeling that they would be at least disinterested in their consideration of the subject, whereas, if it were delegated to a group from the Editorial Association, would it not be sure that the cards were stacked at least against the section on advertising?



But perhaps your editorials refer, in the main at least, —though, if so, you certainly do not make it clear—to what might be called collective advertising, which after all is nothing more or less than a form of medical education of the public. The writer is a doctor, who happens to be at present, and has been for some years, Chairman of the Publicity and Education Committee of Hennepin County Medical Society, and has certainly given this matter a great deal of attention. There are very serious obstacles in the way of any such program on a large scale, though the medical profession is doing what it can under present conditions and will undoubtedly do far more in the future. Still, it may fairly enough be asked why the burden of such a program of publicity and education should fall on the medical profession at all. Why should not the burden be taken up by public institutions of education, if the work that medicine is doing is really a beneficent work and in the interest of the people? For there are, after all, only comparatively few things that it should be necessary to teach and publish—first of all, I should say, the simple rules of hygiene, with as little reference as possible to disease and its symptoms. But in the second place, people should be taught that, while even the doctors know little, in the face of the unexplored ocean of knowledge that confronts them, they still know infinitely more about the human body, perhaps even about the human mind, and certainly infinitely more about the cause, symptoms, and treatment of disease than anyone else whatsoever, and that it would, consequently, be wise for those who need help to turn to them. I would also add a third thing in which it is apparently necessary to educate the public. I refer to the origin, the growth, the scope and the purpose of the medical code of ethics, which exists for their protection and not for the aggrandizement of the medical profession.

J. A. Watson, M.D.

A NEW FINGER SPLINT

The writer recently suffered a drop-finger, due to hyper-flexion, causing a separation of the extensor tendon from the terminal phalanx. The usual splints, with adhesive, etc., were uncomfortable, uncleanly, and very bulky. I then devised a splint which possessed none of these disadvantages. This consists of two metal rings, one fitting over the end of the finger about one-fourth inch from the tip; the other, just large enough to slip over the proximal phalanx, and resting in the groove between the finger and the palm. The two rings are connected by three bars, one on each side of the finger, and the third over the dorsum of the finger. This holds the finger in fixed extension, but permits the hand to be washed, and to perform most of its usual function, without the inconveniences associated with most splints. The splint would serve as well for dislocations or fractures of the phalanges if the metacarpo-phalangeal joint does not also require fixation.

This splint was easily and inexpensively made in a

dental laboratory, the length and circumferences of the finger being first measured.

Platinoid metal was used, the parts being 1/16 inch thick, and 1/8 inch wide; the splint weighed only one-half ounce. German silver will serve equally well. While the principle of the splint is not particularly new, the writer was unable to find anything like it in the instrument houses.

Thomas Myers, M.D.
St. Paul, Minnesota.

ANTIPNEUMOCOCCUS SERUM

Antipneumococcus Serum Combining Types I and II Pneumococci, and Refined and Concentrated Antipneumococcic Serum (Lederle) Not Acceptable for N. N. R.—The Council on Pharmacy and Chemistry reports that it has accepted for New and Non-official Remedies preparation of antipneumococcic serum for Type I pneumococcus infection and that at present this is the only type in which the efficacy of serum has been sufficiently established to warrant general use. The Council reports that there is some evidence that Type II serum concentrated by the Felton method is of service if given early and in large doses, but that there are other reports which indicate inefficacy. In consideration of the present available evidence, the Council declared all serum preparations combining Type I and Type II pneumococci, including Refined and Concentrated Antipneumococcic Serum (Lederle) unacceptable for New and Non-official Remedies. (Jour. A. M. A., September 27, 1930, p. 935.)

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and St. Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associated Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of November will be as follows:

November 5th—Poliomyelitis.
November 12th—Treatment of cataract.
November 19th—Carcinoma of the lip and mouth.
November 26th—Psoriasis.

TENTATIVE PROGRAM FOR MEETING OF MINNESOTA SOCIETY OF INTERNAL MEDICINE

Rochester, Minnesota
November 10, 1930

MORNING SESSION

"An unusual deficiency syndrome secondary to duodenal occlusion" ..... Albert M. Snell
"An unusual type of congenital heart lesion" ..... Edgar T. Herrmann
"The application of the string galvanometer to the diagnosis of adherent pericardium" ..... Morris H. Nathanson
"Transient atrioventricular conduction disturbance following strain" ..... Paul G. Boman
"What is Grace Medes Tyrosinosis?" ..... Hilding Berglund
"Subcutaneous emphysema with a case report" ..... John A. Lepak
"Tests of renal function in patients with prostatic hypertrophy with special reference to phenolsulphonphthalein" (by invitation) ..... Harold C. Habein

A synopsis of the recent symposium on renal disease at the University of Minnesota

"The features of clinical interest brought out at the Symposium" ..... Moses Barron
"The theoretical features particularly in regard to the normal and disturbed kidney function" ..... George Fahr

Discussion opened by Norman M. Keith

AFTERNOON SESSION

"The principles underlying the recent attempts at classification of arthritis" ..... Morse J. Shapiro
"Further observations on the feeding of swine in cases of pernicious anemia" ..... H. Milton Conner
"Agranulocytic angina" ..... Rudolph C. Logefeil
"The development of tuberculosis among nurses" ..... Everett K. Geer
"An unexploited therapeutic opportunity in periodic health examinations of young adults" (by invitation) ..... Norman Johnson
"A study of migraine in University students" (by invitation) ..... Lewis Daniel
"The cortical hormone of Swingle and Pfiffner in the treatment of Addison's disease" ..... Leonard G. Rowntree

Symposium on experimental peptic ulcer
Frank C. Mann (by invitation)
Edward C. Rosenow (by invitation)
George B. Eusterman

EVENING SESSION

Address—"Energy" (by invitation) ..... Charles Sheard

NORTHERN MINNESOTA MEDICAL ASSOCIATION

At the annual meeting of the Northern Minnesota Medical Association, held at Moorhead, Minnesota, September 29 and 30, 1930, the following officers were elected for the ensuing year: President, Dr. B. S. Adams, Hibbing; vice president, Dr. G. S. Wattam, Warren; secretary-treasurer, Dr. O. O. Larsen, Detroit Lakes.

Hibbing was chosen for the 1931 meeting, which will be some time in August.

The meeting was addressed by Mr. Lou Beaushoop, editor of the Detroit Record, who told the ninety physicians attending the banquet at the Comstock Hotel that the medical code of ethics is "too restrictive" and that the public suffers because of the failure of reputable doctors to make full use of the press.

The Reverend Dr. Sainsbury, Fargo, also a speaker at the banquet, explained in detail England's compulsory health insurance, which creates a "consciousness of health in all minds." He, however, declared it was not likely that this system would be applicable in the United States.

Dr. H. C. Cooney, Princeton, delivered the presidential address, calling attention to the fact that the profession had made greater progress in the last forty years than in the 2,000 years preceding.

Dr. A. E. Meyerding, State Secretary, commenting on Mr. Beaushoop's address, urged newspapers to seek authentic sources for medical information in order to insure correctness and called attention to the fact that the organized profession is prepared to coöperate with the press.

O. O. Larsen, M.D.
Secretary.

PARK REGION DISTRICT AND COUNTY MEDICAL SOCIETY

The annual meeting of the Park Region District and County Medical Society was held in Alexandria, October 8, 1930. The following officers were elected: President, Dr. A. J. Lewis, Henning; vice president, Dr. F. Naegeli, Fergus Falls; secretary-treasurer, Dr. E. A. Heiberg, Fergus Falls.

A series of lectures on various cardiologic subjects was begun with a discussion of "The Management of

the Ambulant Cardiac Patient" by Dr. G. E. Fahr of the University of Minnesota. The Society and Auxiliary were the guests of the Park Region District Druggists Association at dinner. The non-members of the district were invited to attend this meeting, and an appeal was made to them to become active members. The Society is now conducting a Postgraduate University Extension Course, with about 30 members in attendance.

WEST CENTRAL MINNESOTA MEDICAL SOCIETY

The annual meeting and banquet of the West Central Minnesota Medical Society was held at the Merchants Hotel, Morris, Minnesota, October 8, 1930. Dr. A. T. Arneson of Starbuck read a paper on "Blood Chemistry" and Dr. C. L. Scofield of Benson a paper on "The Relation of Physicians to the State Board of Health."

The following officers were elected for the ensuing year: President, Dr. A. E. Eberlin, Glenwood; vice president, Dr. E. T. Fitzgerald, Morris; secretary-treasurer, Dr. A. L. Lingberg, Wheaton.

The next regular meeting will be held jointly with the Kandiyohi-Swift County Medical Society at Benson.

CHARLES BOLSTA, *Secretary.*

HOUSTON-FILLMORE COUNTY MEDICAL SOCIETY

A meeting of the Houston-Fillmore Medical Society was held at Harmony, Minnesota, September 25, 1930.

A letter from Dr. Herman Johnson was read. Mr. Brist then gave a talk on the work done by the State Board of Medical Examiners which was followed by a talk on "Gastro-intestinal Diseases of Children," by Dr. Kennedy of the Mayo Clinic.

The following officers were elected: President, N. E. Anderson, Harmony; vice president, C. B. Eby, Spring Valley; secretary, R. N. Palmer, Lanesboro; treasurer, J. C. Lannin, Mabel.

Dr. William E. Johnson of Caledonia, Minnesota, was elected to membership.

J. W. HELLAND, M.D.
Secretary.

SCOTT-CARVER COUNTY MEDICAL SOCIETY

The regular meeting of the Scott-Carver County Medical Society was held at Belle Plaine, Minnesota, on Tuesday, October 14, 1930. Dr. M. O. Henry of Minneapolis spoke on fractures and presented motion pictures of Boehler's method of treating fractures. The invitation of Dr. Fred Westerman to meet at Montgomery in November was accepted.

B. H. SIMONS, *Secretary.*

RICE COUNTY MEDICAL SOCIETY

Rice County Medical Society held a meeting Tuesday, September 23, 1930, in the main building at the State School for Feeble Minded at Faribault.

Dr. A. M. Hanson, delegate, reported on the meeting of the Minnesota State Medical Association.

Dr. D. W. Francis of Morristown read a paper on "Pneumonia."

C. J. PLONSKE, *Secretary.*

WASHINGTON COUNTY MEDICAL SOCIETY

The Washington County Medical Society held their October meeting at the Stillwater Club rooms. The guest speaker was Owen H. Wangensteen, M.D., Department of Surgery, University of Minnesota. His subject was "Cancer of the Stomach." He gave us a wonderful lecture with fine illustrations. It took him about two hours to deliver this. It was followed by a discussion or rather questions by members of the local society; the questions were very well answered. We feel that we received a great amount of valuable information and appreciate greatly Dr. Wangensteen's kindness in addressing us. Outside doctors were Dr. Simonstad and Dr. Gleeson of Osceola, Wisconsin.

E. SYDNEY BOLEYN, Secretary.

RED RIVER VALLEY MEDICAL SOCIETY

A meeting of the Red River Valley Medical Society was held at Warren, Minnesota, October 9, 1930.

The following scientific program was presented:

Sciatica—DR. A. P. MACKINNON, Winnipeg.

Fractures of the Upper End of the Femur, not including the Hip—DR. R. C. WEBB, Minneapolis.

Hip Fractures—DR. O. J. ENGSTRAND, WARREN.

Some Phases of Organized Medicine—DR. S. H. BOYER, Duluth.

Observations of European Clinics—DR. H. W. FROEHLICH, Thief River Falls.

C. L. OPPEGAARD, M.D.
Secretary-Treasurer.

LYON-LINCOLN COUNTY MEDICAL SOCIETY

At a meeting of the Lyon-Lincoln County Medical Society held in Marshall, October 1, 1930, the following officers were elected:

W. W. Yaeger, Ivanhoe, Minn.....President
E. L. Erickson, Hendricks, Minn.....Vice President
H. M. Workman, Tracy, Minn..Secretary and Treasurer
A. D. Hoidale, Tracy, Minn., ...Censor 3 years
E. L. Sanderson, Minneota, Minn.....Delegate
A. L. Vadheim, Tyler, Minn.....Alternate

The Society opened their second Clinical Course with Doctor Rood Taylor on "Pediatrics." Twenty-six were present.

H. M. WORKMAN, M.D., Secretary.

ST. LOUIS COUNTY MEDICAL SOCIETY

The annual meeting of the St. Louis County Medical Society was held Thursday, October 9, 1930, following a banquet at the Northland Country Club, Duluth, Minnesota.

The officers elected for the coming year were: President, Dr. F. J. Lepak, Duluth; vice president, Dr. T. A. Estrem, Hibbing; secretary-treasurer, Dr. Mario Fischer, Duluth.

Censors for the coming year are: J. M. Robinson, Duluth; E. L. Tuohy, Duluth, and B. F. Davis, Duluth.

Delegates to the Minnesota State Medical Association are: C. L. Haney, Duluth; B. S. Adams, Hibbing; J. R. Manley, Duluth; F. H. Magney, Duluth; Alternates—O. W. Parker, Ely; C. A. Scherer, Duluth; B. F. Davis, Duluth; A. N. Collins, Duluth.

The meeting was addressed by Dr. E. W. Sainsbury of Fargo, North Dakota, who discussed his recent travel experiences in Europe, including Russia, and certain phases of the medical economic problem in Great Britain.

M. McC. Fischer, M.D.,
Secretary.

WRIGHT COUNTY MEDICAL SOCIETY

The annual meeting of the Wright County Medical Society, and election of officers, was held at Buffalo, Tuesday, October 7, 1930.

Officers elected are: President, Dr. John J. Catlin, Buffalo; vice president, Dr. Verner P. Johnson, Delano; secretary-treasurer, C. L. Roholt, Waverly.

Dr. E. Klaveness, Monticello, was elected as delegate to the state meeting, with Dr. O. J. R. Freed, Cokato, as alternate.

John J. Catlin, M.D.
Secretary.

EPHEDRINE AND HABIT FORMATION

An article appeared in a recent issue of the Ladies Home Journal in which it was stated that ma huang is closely related to cocoa and that it is as dangerous as the narcotics of the cocoa group. It stated: "Ma huang . . . has cocaine's effects—it is exhilarating, habit forming, deadly." Chen and Schmidt in a recent monograph, "Ephedrine and Related Substances" state that investigators appear to agree that the prolonged use of ephedrine does not have any cumulative harmful effects and does not result in habit formation. In New and Non-official Remedies, no reference is made to habit-forming properties of the drug. A search of the Quarterly Cumulative Index Medicus fails to reveal published articles on ephedrine as a habit-forming drug. Though it is known that the actions of ephedrine on the central nervous system resemble considerably those of cocaine, it is not believed that these are sufficiently pleasant to be a temptation; certainly the effects cannot be at all serious, or they would have become apparent before this. In a recently published report of the effects of ephedrine on animals it is stated that in humans, after prolonged use against asthma, it produced euphoria, and reports where the drug had to be discontinued on account of unpleasant stimulation. The absence of clinical reports of addiction does not substantiate the careless references of popular writers to habit formation. The available evidence indicates that there is little if any danger of ephedrine becoming a serious habit former. (Jour. A. M. A., September 3, 1930, p. 731).

PROCEEDINGS MINNESOTA ACADEMY OF MEDICINE

Meeting of September 10, 1930

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, September 10, 1930. Dinner was served at 7 o'clock and the meeting was called to order by the President, Dr. Emil S. Geist, at 8 p. m. There were 42 members present.

Minutes of the May meeting were read and approved.

The Secretary also read the report of the Executive Committee meeting of August 7th and a motion was carried that this be adopted.

Upon ballot Drs. F. L. Adair and F. W. Schlutz, formerly of Minneapolis, and Dr. H. C. Cooney of Princeton were elected to Honorary Membership in the Academy, and Dr. F. F. Callahan of Pokegama Sanatorium was elected to Associate Membership.

Owing to Dr. Alexander Stewart's inability to be present, his Thesis on Serotherapy in Scarlet Fever was not read at this meeting.

Dr. A. A. Zierold (Minneapolis) then read his Thesis, entitled "Morphine as a Diagnostic Agent."

DISCUSSION

Dr. A. T. Mann (Minneapolis): I think this paper brings up a very interesting subject. I remember when I first came here the older surgeons spoke about the differentiation of rigidity by the use of morphine but they certainly did not work with it in such a careful way or go so far into its logical basis. There is a great deal of truth in the paper. I think our old idea of the withholding of morphine in abdominal conditions pivots around the fact of whether a thorough examination has been made before the morphine has been given. Personally, I can't see any reason at all for withholding morphine after a thorough and careful examination has been made and diagnostic judgment has been used. There is no doubt at all about administering morphine at that time and I think it is a very valuable thing.

Abdominal pain and abdominal tenderness are two different things. There was nothing brought out in the paper in regard to tenderness. We do get tenderness in various places from troubles at a distance. For example, we can have the tenderness that is ordinarily associated with gallbladder or with ulcer of the duodenum, from appendicitis or from an inflammation in the pelvis because of the distribution of the lymphatics. The tenderness which we ordinarily get with appendicitis comes apparently quite definitely over the first lymphatic group at the base of the mesentery, *i.e.*, under McBurney's point. The appendix travels around like the spoke of a wheel but the tenderness stays where the root of the appendix is. If that continues for some time and some of the inflammation leaks through this first bunch of glands into the next ones, which are just to the right of the aorta, then we have a second point of tenderness, Morris' point of tenderness, about one and a half inches from the midline, *i.e.*, over the juxta-aortic glands. If the inflammation trav-

els up this chain of lymphatics it may reach the upper glands of this chain at the level of the duodenum and give a deep point of tenderness suggestive of the tenderness elicited from a duodenal ulcer or sometimes that from an infected gallbladder.

The question I should like to ask the essayist is, what influence these changes would have on the abdominal rigidity and the influence of the morphine on these changes.

Dr. W. F. Braasch (Rochester): The paper this evening is a most interesting one and the Doctor is to be congratulated upon his thesis. I was particularly interested in one case in which epigastric pain was predominant and after the administration of morphine the pain was referred to the appendix. The relationship between epigastric pain and appendicitis is clearly emphasized.

As far as the urinary tract is concerned, the areas of pain reference as described by Head and others have not proven to be of value in the localization of pain. With stone in the ureter the pain is almost always referred to the renal area. After the administration of morphine the pain either remains in the kidney area or it is stopped. I do not recall any case where the renal pain was transferred to the ureter after the administration of morphine. As far as the bladder is concerned, bladder pain very seldom has to be differentiated and therefore is not strictly applicable to these theories.

Somewhat related to this subject is the work of Learmonth in disturbance of innervation of the bladder, recently published in *Surgery, Gynecology and Obstetrics*. Bladder innervation and various types of pain and disease of the bladder are discussed, together with original observations on physiology. We have observed a number of patients with unbearable pain referred to the bladder who were completely relieved by sympathectomy without disturbing the mechanical action of the bladder. The whole subject of the innervation of intra-abdominal, as well as urinary, organs is one of great interest and I believe there will be much progress made in this field.

Dr. E. L. Gardner (Minneapolis): I have seen some of Dr. Zierold's work at the General Hospital and know that it is good clinical observation. Almost twenty years ago I had the privilege of being with Dr. J. W. Bell for a while, and there were two procedures which he regularly used. One was the old-fashioned hot tub. A patient with an acute abdomen was put into a hot bath and the abdomen palpated while in the tub; this often relieved rigidity and helped to localize the lesion. The other method was to give ¼ of a grain of morphine and proceed with the examination. This diffuse type of pain and generalized rigidity seems to occur in certain high-strung individuals. Even in chronic conditions, such as in duodenal ulcer, it is not infrequent to have the primary pain referred to the upper epigastrium. Very soon, if this patient is irritable, we sometimes have a "slopping over" of pain and muscle spasm to segments above, or less often, below. By taking a very careful history in these cases we can often arrive at a pretty good diagnosis without laboratory procedures.

I think Dr. Zierold's contribution is a good one. It brings to us an old procedure better explained in modern physiologic terms.

Dr. J. S. Gilfillan (St. Paul): This paper is a very valuable one and I think it explains a little more clearly to us why we get the alteration in abdominal rigidity after giving morphine. We used to feel a little hesitancy in giving morphine in acute abdominal conditions and my own idea was that there was some danger until we had decided definitely whether or not an operation was to be done. One danger in giving morphine is to get the patient to consent to operation after you have taken the pain away. I was wondering, as I listened to the paper, if the same procedure might be applied to extra-abdominal conditions.

Dr. Zierold (in closing): You have all been very generous and I appreciate the kindly consideration that you have shown me. The questions are all very fair ones and I think can be reasonably well met.

Dr. Gilfillan commented on the possibility of using some such procedure as this in the diagnosis of joint conditions. I have been trying to check some of the chronic joint conditions but haven't enough clinical material as yet. I do know that in hip-joint disease morphine will resolve the spasm to its proper segment. I have found it to work very satisfactorily in acute joint infections, particularly in children.

Dr. Mann presented the question of pain and tenderness. I purposely avoided stressing pain and tenderness. They are more or less an incident in muscle spasm. As a result of the pain there is a purposeful spasm. The simple contraction of muscle not attended by pain is a simple reflex. As Dr. Mann so well noted, the pain and tenderness may occur in remote and rather bizarre places.

Dr. Braasch raised again that same point with regard to tenderness and brought up very aptly Head's theory in regard to referred pain, which unfortunately does not always work out. It is interesting to hear of Dr. Learmonth's work on the bladder nerves, particularly when one recalls the difficulties to be overcome.

Dr. Gardner mentioned Dr. Bell's observation, of which he had told me before and which we have discussed previously. He reiterated what I meant to say in the beginning, *i.e.*, that the clinical phase of this phenomenon is not new.

Dr. Ulrich asks as to the effect of morphine; as to whether it reduces or heightens the threshold of reflex stimulation. Morphine affects only the cortical centers. It has no effect on the spasm which is an exaggerated spinal reflex.

Dr. Wallace H. Cole reported a case of "Leg Lengthening of the Tibia in Infantile Paralysis" and showed numerous lantern slides taken before and after the operation. (This paper will be published in the December number.)

The meeting adjourned.

R. T. LaVake, M.D.
Secretary.

Meeting of October 8, 1930

The regular monthly meeting of the Minnesota Academy of Medicine was held at the Town and Country Club on Wednesday evening, October 8, 1930. Dinner was served at 7 o'clock and the meeting was called to order by chairman of the Executive Committee, Dr. F. E. Burch, in the absence of the President and Vice-President, at 8 o'clock. There were 46 members and 2 visitors present.

Minutes of the September meeting were read by Dr. Carl B. Drake, in the absence of the Secretary. These were approved.

Letters were read from Dr. F. L. Adair, Frederick W. Schlutz, of Chicago, and Dr. H. C. Cooney, of Princeton, Minnesota, each thanking the members for his election to honorary membership in the Academy. A letter was read from Dr. R. O. Beard calling attention to the meeting of the Postgraduate Assembly in the Minneapolis Auditorium, the week of October 20th and extending an invitation to attend.

Dr. H. P. Ritchie of St. Paul read the following memorial to Dr. Arthur A. Law:

Arthur Ayer Law was born at Harvard, Illinois, April 16, 1872, and died at his home in Minneapolis July 9th, 1930. He was active in attendance upon a large and select surgical practice until May, 1930, at which time some premonitory symptoms developed to a point which required a complete cessation of his work.

After graduation at the Shattuck Military Academy, he entered the University of Minnesota Medical School, from which he received the diploma of Doctor of Medicine with the class of 1894. From that time on he held a teaching position in surgery, advancing through ever increasing responsibility to that of Associate Professor of Surgery and at one time Assistant Chief of the Department. He was a prominent member of the first surgical staff of the University Hospital, which was formed upon the opening of that institution, under the masterly direction of the late Dr. James E. Moore. He took a great part in the development of the school; was positive in his opinions on policies of administration and forms of teaching, was not always in accord with others as becomes a man of individuality, but was ever constant in the hope for, and belief in, the future growth of the school; was generous of his time, tireless in effort, deep in his interest. He was always prompt to meet his lecture engagements; he was exacting in the proper care of his patients. He early developed a reputation, augmented and enhanced as the years went on, as a surgeon known for the dexterity, celerity and precision of his operative work. His association with the University continued until 1929, when upon his resignation he received from the Board of Regents an acknowledgment of his years of service, couched in positive terms of appreciation, a document of which any one would be proud and which a few are entitled to receive.

He was an officer in two wars. In the Spanish American War he was Captain and Assistant Surgeon of the 13th Regiment of Minnesota Volunteers, serving in that position during the entire term of duty with that regiment in the Philippines. In the World War he was Colonel and Commanding Officer of Base Hospital No. 26 and served in France. He received a citation from General Pershing for "service over and beyond the call of duty." This official statement is a fitting epitaph.

He had a standard of impeccable personal conduct, a strict and stern sense of responsibility of his work, a devotion for and to his family. Those who were priviliged to enter his beautiful home found in him a thoughtful, generous and gracious host. To his close friends he gave, to quote a favorite and oft-repeated expression, "a touch of the shoulder."

He was a member of other local societies and several of national scope: the American Surgical, the Western Surgical, the Southern Surgical, the American College of Surgeons, to each one of which he has presented contributions to the Science of Surgery. He was long a member of the Minnesota Academy of Medicine and upon the occasion of his death your committee offers the following resolution:

WHEREAS: Arthur Ayer Law has passed from this life, his membership in the Minnesota Academy thereby terminated and personal contact severed

BE IT RESOLVED THAT the Academy of Medicine acknowledge the years of their association, express regrets at his departure, cause the above sentiments to be spread upon the minutes and instruct the Secretary to send a copy to his family.

Signed: H. B. Zimmermann,
Martin Nordland,
Harry P. Ritchie, *Chairman.*
Committee.

The scientific program of the evening was then taken up.

Dr. J. Charnley McKinley (Minneapolis) read his thesis entitled "Familial Diffuse Sclerosis of the Brain."

Drs. F. E. Foley and Arnold Schwyzer (St. Paul) presented a paper on "An Improved Pelvioureteroplastic Operation for Hydronephrosis." Dr. Foley read the paper which was illustrated with numerous lantern slides.

DISCUSSION

Dr. H. P. Ritchie (St. Paul): The only comment which I feel qualified to make on this very excellent presentation is on the question of the flap of the pelvis. The flaps as shown appear entirely too acute. I presume this is only apparent in the illustration and not real in the operation. We know that the life of a flap is dependent on the blood supply to all parts of it. It seems to me that with all the abundant tissues of a dilated pelvis it would be just as easy to prepare the flaps in such a way as to be very sure of the maximum blood supply. I was thinking of the death of some part of the flap and an inflammatory stricture.

Dr. Foley: I would like to ask Dr. Ritchie about

what angle he would think was best for cutting the flap.

Dr. Ritchie: I suggest a little wider sweep on the tip; a curve and not such an acute angle. In skin flaps, if the flaps are too sharply cut a necrosis of the tip follows.

Dr. Foley: It would be difficult to make the point of the flap fit down onto the ureter. The flap is quite short. I would say the angle is about 60 degrees.

Dr. Ritchie: I am not familiar with the size of the flap. If it is so cut, my comment is of no value.

Dr. Schwyzer: I am very happy that Dr. Foley took the interest that he did in this procedure. If I was father of the child, he was the doctor who saved the child from the death of oblivion and has shown a modification of the procedure which in appropriate cases yields a perfect result.

In answer to Dr. Ritchie's remarks, of course we want to be sure that we have a living flap. The important feature is that the stricture is held open not by the tip, but by the base of the flap, which is at this point about one centimeter wide. Thus, even if the tip should necrose, which is has not done so far, it would be at least one centimeter away from the danger point. It is, of course, good to watch out for the proper circulation. There should not be any tension on the flap at all.

The meeting adjourned.

R. T. LaVake, M.D.
Secretary.

TWO MINOR MAIL-ORDER FRAUDS

Chinese Herb Co. of San Francisco, and Webb Co., Springfield, Ill., have been debarred from the mails. The Chinese Herb Co. sold "herb treatments" through the mails for the alleged cure of practically all diseases and ailments. The Webb Co. sold through the mails a mechanical device called the "Adjustor," sold under the claim that it would develop the male sexual organ. (Jour. A. M. A., September 6, 1930, p. 745.)

VENTRICULIN

The Council on Pharmacy and Chemistry publishes a preliminary report on Ventriculin. It was presented by Parke, Davis & Co. for consideration by the Council as a preparation of desiccated stomach tissues usefui in the treatment of pernicious anemia. The Council has postponed definite action in regard to the acceptance of Ventriculin to await (1) presentation by Parke, Davis & Co. of a definitely standardized method of preparation for the product, (2) justification of the name, including a signed statement by Drs. Sturgis and Isaacs concerning the discovery of the use of stomach tissues in the treatment of pernicious anemia, and (3) presentation of adequate clinical evidence for the efficacy of the product in the treatment of pernicious anemia. (Jour. A. M. A., September 13, 1930, p. 797.)

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

EYE, EAR, NOSE AND THROAT

THE SINUS IN PERSPECTIVE: Arthur W. Proetz, M.D., St. Louis (Ann. of Otol., Rhinol. and Laryng., Vol. XXXVIII, No. 3, p. 682, Sept., 1930). We know discouragingly little about sinuses, and only exert a feeble influence upon their welfare.

We know, in a word, that a sinus is an air cavity communicating with the nose; that it is capable of infection and that when its ventilation and drainage are impaired trouble ensues. We know in a general way what are the symptoms of such infections and blockades, and too often we are mistaken even in these. We have devised dozens of more or less ingenious ways of opening these cavities, all for one purpose—to let out infectious material—which sums up virtually the whole of sinus surgery, and cannot be considered a step ahead of the elementary surgical principle of draining an abscess anywhere in the body, as practiced by the ancients. Our treatment plays a pathetic role in the process of repair which Nature institutes and effectively pursues.

Naturally it must remain for the few to make the

epochal discoveries upon which a science grows, but at the same time it is the responsibility of the many to unburden themselves of the charms, curses and fetishes of the past, and to familiarize themselves in extenso with the underlying facts of physiology and pathology. The mere mention of swollen membranes is a red rag to some of us. Swollen ankles merit only passing attention. Pus encountered in the nose is a fair indication that nature is at work successfully expelling noxious agents from our confines, and while I do not view it as a signal for jubilation I see no occasion for hysteria in regard to it.

I am increasingly impressed with the probability that the chronicity of many sinus infections depends not upon the failure of the body to throw off some old initial infection, but upon the daily reinfection with some strain of microörganism to which the subject is nonresistant. It is as though the patient were taking daily some noxious drug which was discontinued for a time and later resumed. To my mind this explains the sophistry "once a sinus always a sinus" which the laity now sententiously quote. Unfortunately it comes too near the truth, which is my one excuse for this diatribe.

I spend sleepless nights thinking about the physicians of old contemplating arteries and the spurting of blood for centuries before they sensed the secret of the circulation. Fifteen hundred years elapsed before curiosity supplanted reverence for authority and amended the quaint physiology of Galen. I realize what remains to be done for sinuses, and pray that no such centuries will pass before some scientific light is thrown upon these dark cavities which lie above and beside and behind—not to say under—our very noses.

Arthur C. Dean, M.D., F.A.C.S.

BRAIN ABSCESS FROM THE STANDPOINT OF THE OTOLARYNGOLOGIST: Wells P. Eagleton (Trans. Amer. Acad. Ophth. and Otolaryngol., Page 64). There is a direct relationship between the intermedullary blood supply and the meninges, as every cerebral vessel is surrounded by a prolongation of the pia arachnoid to form a perivascular space. This makes for an easy route of infection for the formation of brain abscess. Added to this, all the veins within the dura have no outer coat; the walls are simply a layer of endothelial cells. The place of the outer coat, the adventitial coat of the extra-dural veins, is formed by the perivascular space prolongation. In this way venous channels and perivascular spaces are the chief routes of infection in brain abscess, originating from a retrograde thrombophlebitis or a perivascular space invasion. A chill differentiates between these two.

Infarcts occur frequently and many are not recognized as patients recover if the vascular occluding nidus is not infected or when the infection is overcome by the protective reaction of the surrounding arachnoid. Some of these cases cause a suppurative meningitis, and others remain quiet for a long time, and then develop an abscess.

Subdural space abscesses occur frequently, especially over the frontal lobe, making up about 25 per cent of these cases. They are easily missed if exploration takes place through too small an opening. In the temporo-sphenoidal lobe they are uncommon, but are fairly frequent over the tentorium, under the occipital lobe. All cases of infection through the ductus endolymphaticus are in reality intradural abscesses, which are apt to become subdural space collections. If these are diagnosed early and operated upon, a high percentage of recoveries should be obtained. This form of abscess is apt to result when the superior semi-circular canal has been eroded or following a mastoidectomy, during which there has been injury to the dura. All these cases require a large dural incision.

Aids to Diagnosis in Brain Abscess.—1. Careful notes should be made, in doing every mastoid operation, of any abnormalities, for, later, if any intracranial involvement occurs, the focus and its means of spreading anatomically may be understood.

2. If the labyrinth has recently ceased to function the path of infection is likely through it, and has entered the dura through the internal auditory meatus.

3. A patient with a suppurating ear, who vomits without any manifest reason, is experiencing some sort of dural involvement.

4. Routine visual fields should be taken daily, as they may vary greatly. They can only be taken early, when the patient is able to coöperate.

5. The value of nystagmus. In intracranial lesions, one should forget much that has been taught, as to the localizing value of the direction of the nystagmus. A few points are of much value as: (a) a vertical nystagmus either spontaneous or induced suggests a brain stem involvement, (b) a changing spontaneous nystagmus suggests a retro-labyrinthine involvement, (c) a vertical diplopia associated with or followed by a spontaneous nystagmus suggests a deep, mid-brain collection in the anterior segment of the posterior fossa.

Do not do a spinal puncture in any case of abscess suspected to be in either the posterior fossa or any part of the mid-brain cone.

Do not administer ether when unnecessary.

Operative Results.—There has been on appreciable improvement in results in cases of temporo-sphenoid abscess. The results in cerebellar abscess have improved probably due to the increased area of bony decompression as done at present. In cases of intradural suppuration of the frontal region, there has been a marked improvement.

L. G. Flanagan, M.D.

APPENDICITIS FOLLOWING TONSILLECTOMY: H. C. Ballenger (Arch. of Otolaryn., July, 1930, p. 67). Appendicitis following tonsillectomy is apparently not common, judging from the literature, as a careful search failed to reveal any cases reported. That such a relationship may exist is probable, for during recent years it has become increasingly evident that appendicitis or peritonitis may follow acute or chronic tonsillitis. In 1916 Anderson reemphasized the apparent relationship between infection of the upper respiratory tract and that of the appendix. Such a

relationship is suggested by the similar lymphoid tissue in the two structures and by the frequently noted incidence of appendicitis during an epidemic of throat infections.

Evans reported eight times as many cases of appendicitis during the time of an epidemic as when there was no epidemic. He found an infection of the upper respiratory tract in 86 per cent of his cases of appendicitis.

Nearly all observers are convinced that this relationship exists. However, the method by which the transmission of the infection from the throat to the appendix occurs is not so clear; whether the bacteria are carried by the alimentary canal, the lymph system or the blood stream is still a matter of question. Possibly all three channels are used at times.

That the infection may be transmitted by way of the alimentary tract was demonstrated by Chastenet, who obtained a subsequent appendicitis in rabbits by feeding them with pathogenic bacteria. In many cases the infection is transmitted by way of the blood stream. Poynton and Payne reported a case in which they seem to prove almost conclusively that a cause of appendicitis may be a streptococcal invasion through the blood stream from follicular tonsillitis.

The removal of the tonsils and adenoid may possibly be a factor in producing or inciting appendicitis in view of the generally accepted opinion that appendicitis is frequently a result of acute or chronic tonsillitis.

Gerald M. Koepcke, M.D.

GYNECOLOGY AND OBSTETRICS

EXTEMPORANEOUS EVACUATION OF THE UTERUS UNDER SPINAL ANESTHESIA: Paul Delmas (Bul. Soc. Gynec. et Obstet., April, 1928, p. 413). The author describes his method of emptying the uterus at an appointed time, without operative or accidental laceration of soft parts.

He believes that spinal anesthesia: (1) prevents contracture or tetanic contraction of the uterus; (2) does not interfere with normal uterine contractions; in fact, that these are actually stimulated.

He explains that the posterior nerve roots are impregnated with the anesthetic, thus breaking the reflex arc and forming a physiologic block to the conduction of painful stimuli from the genital tract. The intrinsic nerve supply is not affected, so normal contractions take place with no inhibition from the central nerve system.

He uses an adequate dose of anesthetic dissolved in cerebrospinal fluid. Dilatation is rapidly accomplished manually, and either forceps or version selected on basis of obstetrical indications. The method was used in about 5 per cent of the cases in his institution and results were uniformly satisfactory. The third stage was usually physiological. Uterine retraction was uniformly spontaneous and adequate.

As contra-indications he recognizes: Operative or traumatic scars of the cervix; inflammatory or cautery cicatrix; malignant disease of the cervix; tetany or contracture of the uterus or cervix.

He has used the method for the following conditions: To induce labor prematurely in case of contracted pelvis, or for at term hydramnios or prolonged pregnancy; toxemia or eclampsia; premature rupture of membranes; placenta previa; during labor in case of undue delay.

A. L. McDonald, M.D.

ERGOTISMUS GANGRENOSUS: Philip Oginz (Amer. Jour. Obstet. and Gynec., Vol. XIX, No. 5). Serious cases of ergot gangrene are rarely reported. The author furnishes details concerning a patient who received a single dose of fluid extract of ergot following labor. Then, because of sepsis, she was given "Gynergen" by hypo every four hours over a period of ten days. Numbness and tingling of the feet and limbs suggested a diagnosis of saddle thrombus of the common iliac, and surgical intervention was seriously considered. Finally ergot poisoning was diagnosed and the drug discontinued. The condition cleared but only with the loss of all toes of the right foot. Idiosyncrasy to ergot should always be considered and long continued medication with ergot avoided.

A. L. McDonald, M.D.

A TEST OF LABOR: John M. Lafferty (Amer. Jour. Obstet. and Gynec., Vol. XIX, No. 5). The author adopted the test described by Tweedy, which includes: A record of the maternal temperature and pulse, and of the fetal pulse every two hours. A rise of the maternal pulse or temperature above 100 indicates interference on behalf of the mother.

A fetal pulse over 160 or under 120, recorded at three successive counts at one minute intervals, requires interference for fetal distress.

The findings of this test were applied to a series of 822 labors with operative interference in 14.7 per cent. The author feels that the test is a reliable guide, inspires confidence during slow labors, and rarely fails to warn of danger in time for intervention. In his experience it has prevented many unnecessary operative deliveries, and has often furnished the only indication of fetal distress.

A. L. McDonald, M.D.

PEDIATRICS

POLIOMYELITIS: George A. Campbell, M.B., and Samuel Mirsky, M.D., Ottawa, Ontario (Arch. of Ped., September, 1930, Vol. XLVII, No. 9). In 1913, Flexner and Noguchi isolated the etiological factor and demonstrated it to be a filter-passing virus and not a bacterium.

Sixty per cent of the cases occur in males. Sixty per cent of the cases are under five years of age, and 95 per cent under ten years in recent epidemics. A second attack is unknown. The period of greatest infectiousness is during the first three or four days of the acute disease.

Three types of cases are recognized:

1. The abortive type.
2. Dromedary type.

3. The acute type, in which the nervous system becomes involved while the general infection is at its acute stage.

Spinal fluid examination is usually helpful in the diagnosis, but renders no aid in differentiating poliomyelitis from encephalitis.

Cells: 50 to 2,000—average 150 to 300. The cerebrospinal fluid is normal in the abortive case and during the first febrile disturbance of the dromedary type. There is usually a leukocytosis of 15,000 to 30,000.

The use of convalescent serum is based on two conclusive experiments of Flexner and his associates, which demonstrate that the potent virus of poliomyelitis is rendered innocuous when mixed with convalescent serum, and that administration of the serum, as late as 24 hours after the monkey has been inoculated with the virus, will prevent the development of paralysis.

The importance of diagnosis in the pre-paralytic stage is emphasized because the intramuscular exhibition of convalescent serum at this stage seems to prevent paralysis.

R. N. Andrews, M.D.

ACUTE OBSTRUCTIVE LARYNGITIS: William L. Bradford, M.D., and Alice D. Leahy, B.S., Rochester, N. Y. (Am. Jour. of Dis. of Children, Volume 40, Number 2). While bacillus diphtheriæ is the most common cause of this condition, there is no doubt that many cases are diagnosed as laryngeal diphtheria which are actually due to some other organism.

The clinical manifestations of diphtheritic and of nondiphtheritic laryngitis are so similar that the actual diagnosis frequently depends on the results of bacteriologic cultures.

The chief symptoms and the number of persons manifesting them were as follows: diphtheritic—difficult breathing, thirty-three; cough, twenty-two; fever, thirteen; hoarseness, fourteen; cold, fifteen; croup, eleven; sore throat, eleven; restlessness, six; vomiting, eight; nondiphtheritic—difficult breathing, twenty-five; cough, eighteen; croup, seventeen; fever, seventeen; sore throat, seven; cold, six; restlessness, four; vomiting, nine.

Stridor, retraction of the chest with increased respiratory rate, cyanosis and the presence of a membrane were the outstanding signs among the diphtheritic group.

Ten of eleven fatal cases of diphtheria and six of seven non-diphtheritic patients were examined anatomically. In the first group, typical diphtheritic membranes were demonstrated, with the recovery of Bacillus diphtheriæ in culture in each case. Secondary lobular pneumonia was present in each case. None showed definite myocarditis.

In the nondiphtheritic cases, postmortem examination revealed edema, injection and granulation of the laryngeal and tracheal mucous membranes. No definite membranes were found, but in all cases considerable mucoid exudate was present in the bronchi. Each case presented definite lobular pneumonia. In this group of cases, cultures from the trachea and lungs were negative for Bacillus diphtheriæ.

The evidence in a study of this group of cases strongly suggests that they were severe types of acute catarrhal laryngitis rather than hemolytic streptococcic infections. In this group of cases the predominating organism found by poured blood-agar plate cultures from the larynx was a green-producing streptococcus. Hemolytic streptococci were insignificant in this series of cases. From the bacteriologic study of this group of cases, it is suggested that green-producing cocci may be of etiologic significance in certain types of acute obstructive laryngitis simulating laryngeal diphtheria.

R. N. Andrews, M.D.

THE DIAGNOSTIC VALUE OF SODIUM FLUORESCEIN IN EPIDEMIC CEREBROSPINAL MENINGITIS: Barnet E. Bonar, M.D., Salt Lake City, and Lyle G. Bailey, M.D., Millwood, Wash. (Amer. Jour. of Dis. of Children, Sept., 1930, Volume 40, Number 3). Sodium fluorescein is a dyestuff that has been used to determine the permeability of the meningeal barrier in health and in disease. Jervell demonstrated that the presence of sodium fluorescein in the spinal fluid within three hours after oral administration was indicative of meningitis, and that inability to detect the presence of sodium fluorescein ruled out the disease.

In 19 cases out of 21 of epidemic cerebrospinal meningitis, the sodium fluorescein test performed early in the course of the disease or before cure was established gave positive results. The absence of positive results in the globulin and sodium fluorescein tests indicates that the meningeal infection was of too short a duration and too slight a degree to give changes of the spinal fluid in the two cases. Both cases died early.

The fact that the concentration of sodium fluorescein was slight in some cases, whereas after treatment the reactions became stronger, suggested the possibility of irritation by the serotherapy increasing the permeability of the meninges.

Ordinarily, the finding of blood in the spinal fluid at puncture makes the fluid nearly valueless for diagnosis. Sodium fluorescein is nonpoisonous, and should not be confused with uranium, which is destructive to the tissue of the kidneys especially.

The test is of value in the differentiation of epidemic cerebrospinal meningitis from other diseases in which sometimes there are manifestation of meningeal irritation, such as pneumonia, erysipelas, spasmophilia, encephalitis, tumor of the brain and tetanus. The presence of small amounts of blood does not invalidate the test, which makes it especially valuable in the diagnosis of meningitis.

R. N. Andrews, M.D.

THE CHILD'S HEART IN HEALTH AND DISEASE: Ronald L. Hamilton, M.D., Sayre, Pa. (Arch. of Ped., Vol. XLVII, No. 7, July, 1930.) A survey of the vital statistics collected during the past decade has demonstrated to us that heart disease is playing the major role in our death rate.

Should we, up to six weeks, examine the infant's

heart we would find a definite right auricular enlargement, which is physiologically normal. Murmur and thrills may be apparent the first few weeks of life, but these should soon disappear.

All children born with cyanosis are not necessarily congenital heart abnormalities, as enlarged thymus, atelectasis of lungs, cerebral hemorrhage, or sepsis may cause the same. The cyanotic group are principally those of pulmonary stenosis, or pulmonary stenosis and atresia. It is extremely important that we diagnose correctly congenital heart disease from organic heart disease.

Patent foramen ovale: Here we should expect little, if any, diminished life expectancy. Ventricular defects are not incompatible with long life, even though they may be complicated with a patent ductus arteriosus. Atresia of pulmonary artery demands a guarded prognosis.

Treatment consists of care in the avoidance of infection, and the mapping out of a good hygienic regime to be followed by the patient. We should be more optimistic in our outlook and remember that the significant aspect of the case is the ability of the heart to work. Even extreme cyanosis should not necessarily influence us to take a too pessimistic view.

Most important are the groups with acute rheumatic fever, chorea, tonsillitis, and those of growing pains. The earliest signs of heart involvement resulting from the above diseases are as follows:

a. A slowing of the heart manifesting a delayed conduction time from auricle to ventricle.
b. An excessive and persistent tachycardia found early.
c. A dropped beat (not a premature beat).
d. A complete transient heart block.
e. Enlargement of the heart.
f. Development of a heart murmur.
g. Pericardial effusion, and at times friction rubs.

Acute rheumatic fever and allied diseases, manifested at times only by growing pains, must be appreciated by the physician as being of significance. Investigators have recently proven that infection may remain in the body, mildly active or in a quiescent stage, from three to five years. A child developing either of these diseases should be kept under the watchful eye of a physician for at least five years, even though convalescence appears to have been uneventful and complete. Good common sense is the greatest asset of the physician in this estimation of activity. Salicylates by mouth (and if gastro-intestinal disturbance, then by rectum) are probably the most important of all medicinal methods of treatment.

Acute infectious disease means potential heart disease. Acute rheumatic fever always means heart disease. Therefore, in infectious diseases, place the heart in its best possible state to resist infection. Never overstimulate a heart that is functioning to capacity—for whipping a tired horse leads but to disaster.

R. N. Andrews, M.D.

NEW AND NON-OFFICIAL REMEDIES

The Council on Pharmacy has accepted the following articles:

Aces Laboratory, Inc.
Mercurochrome Suppositories-Aces

Cutter Laboratory.
Diphtheria Toxoid-Cutter, 45 c.c. vial

Hoffmann-LaRoche, Inc.
Synthetic Thyroxine
Ampuls Synthetic Thyroxine-Roche, 1.1 c.c.
Solution Synthetic Thyroxine-Roche
Tablets Synthetic Thyroxine-Roche, 1 mg.

International Vitamin Corporation
I. V. C. Vitamin Concentrate of Cod Liver Oil

Eli Lilly & Co.
Amytal
Pulvules Sodium Amytal, 3 grains
Old Tuberculin, Human Strain, Concentrated, 2 vial packages

McKesson & Robbins, Inc.
McKesson's Vitamin Concentrate of Cod Liver Oil

E. S. Miller Laboratories, Inc.
Ampoule Sterile Solution Dextrose, U.S.P., 5 Gm., 10 c.c.
Ampoule Sterile Solution Dextrose, U.S.P., 10 Gm., 20 c.c.

National Drug Co.
Antimeningococcic Serum

Parke, Davis & Co.
Gas-Gangrene Antitoxin (Combined) Refined and Concentrated
Soluble Gelatin Capsules, Parke, Davis & Company's Standardized Cod Liver Oil.

Plant Products Co.
Plant's Magnesia Wafers

G. D. Searle & Co.
Chiniofon-Searle
Tablets Chiniofon-Searle, 0.25 Gm. (4 gr.)

C. M. Sorensen Co., Inc.
Inhalant Chloretone Creosote and Eucalyptol-Sorensen

Spicer & Co.
Tartro-Quiniobine
Tartro-Quiniobine Ampules, 2 c.c.

White Laboratories, Inc.
White's Cod Liver Oil Concentrate

Winthrop Chemical Co.
Ampules Emulsion Mesurol, 20 per cent, 1 c.c.
Mesurol
Theocin
Tablets Theocin, 1½ grains

Nonproprietary Articles
Quinine Bismuth Iodide
Sodium Potassium Bismuthyl Tartrate

The following articles have been exempted and included with the List of Exempted Medicinal Articles (New and Non-official Remedies, 1930, p. 477):

H. K. Mulford Co.

Pollen Extracts Diagnostic-Mulford

C. M. Sorensen Co., Inc.

Inhalant Pine Camphor and Eucalyptol-Sorensen

TRUTH ABOUT MEDICINES

The following products have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in New and Non-official Remedies:

Alphanaphthol.—The actions of alphanaphthol resemble those of betanaphthol. The literature is rather contradictory and unsatisfactory as to the relative toxicity, but it is probably of a similar order. Alphanaphthol is employed locally as an antiseptic and germicide; it is not generally used internally.

Alpha Naphco.—Compound Solution of Alphanaphthol. Alpha Naphco contains alphanaphthol 10 Gm., glycerin 32 Gm., soft soap 23.8 Gm., water to make 100 Gm. When tested against *B. typhosus* by the U. S. Hygienic Laboratory method, alphanaphco has a phenol coefficient of 1.46. Carel Laboratories, Redondo, California.

Pyridium.—Phenylazo-2-6-diamino-pyridine monohydrochloride. The monohydrochloride of an azo dye of the pyridine series, phenylazo diamino-pyridine. Pyridium has marked penetrating power and is nontoxic and non-irritant in therapeutic dosage. It is rapidly eliminated through the urinary tract. It is bactericidal in aqueous solution against staphylococcus, streptococcus, gonococcus, *B. coli* and even *B. diphtheriae.* It is proposed for use in gonorrheal infections, urinary diseases, and in colon bacillus and mixed infections. The drug is supplied in the form of Aqueous Solution of Pyridium, 1 per cent; Pyridium Ointment, 10 per cent; and Pyridium Tablets, 0.1 Gm. Merck & Co., Inc., New York.

Pollen Antigens-National.—Liquids obtained by extracting the dried pollen of plants with a 0.5 per cent sodium chloride solution containing sodium bicarbonate and phenol. For a statement of actions and uses, see Allergic Protein Preparations, New and Non-official Remedies, 1930, p. 23. Pollen Antigens-National are marketed in packages of one 5 c.c. vial containing respectively 50, 100 and 250 units per c.c. The following products have been accepted: Ragweed Pollen Antigen-National and Timothy Pollen Antigen-National National Drug Co., Philadelphia. (Jour. A. M. A., July 5, 1930, p. 35.)

Mead's 5 D Cod Liver Oil with Viosterol.—A brand of cod liver oil with viosterol 5 D (N. N. R.). For a discussion of the actions and uses of cod liver oil with viosterol 5 D, see New and Non-official Remedies 1930, p. 257. Mead Johnson & Co., Evansville, Indiana.

Siomine.—Hexamethylenetetramine tetraiodide. Siomine contains 78.5 per cent of iodine. Siomine is decomposed in the intestine with formation of hexamethylenetetramine and iodide, the rate of absorption and excretion being essentially the same as that of inorganic iodides. It therefore produces the effects of ordinary iodides, from which it differs only in that it can be administered in solid form. No therapeutic claims are made for the hexamethylenetetramine component of siomine, this being present only to render the substance insoluble. The dosage is the same as that of potassium iodide. Siomine is supplied in the form of capsules containing respectively ½ grain, 1 grain, 2 grains, and 5 grains. Pitmanmoore Co., Indianapolis.

Ephedrine Nasal Jelly-Maltbie.—It is composed of ephedrine sulphate-N. N. R. 1 per cent, menthol 0.25 per cent and sodium benzoate 0.5 per cent in a glycerite of tragacanth base. For a discussion of the actions and uses of ephedrine sulphate, see New and Non-official Remedies, 1930, p. 167. Maltbie Chemical Co., Newark, New Jersey.

Ephedrine Hydrochloride-P. D. & Co.—A brand of ephedrine hydrochloride-N. N. A. For a discussion of the actions and uses of ephedrine hydrochloride see New and Non-official Remedies, 1930, p. 167. Ephedrine hydrochloride-P. D. & Co. is supplied in the form of capsules containing respectively ⅜ grain and ¾ grain. Parke, Davis & Co., Detroit.

Elixir of Pyramidon.—Each 4 c.c. (1 fluidrachm) contains pyramidon (New and Non-official Remedies, 1930, p. 314) 0.162 Gm. (2½ grains) in a menstruum containing alcohol, 20 per cent. H. A. Metz Laboratories, Inc., New York.

Pyramidon Tablets 1 1/2 grains.—Each tablet contains pyramidon (New and Non-official Remedies, 1930, p. 314) 1½ grains. H. A. Metz Laboratories, Inc., New York.

Thio-Bismol.—Sodium Bismuth thioglycolate. A salt formed by the interaction of sodium thioglycolate and bismuth hydroxide containing approximately 38 per cent of bismuth. Thio-bismol is proposed as a means of obtaining the systemic effects of bismuth in the treatment of syphilis (Bismuth Compounds, New and Non-official Remedies, 1930, p. 94); it is a water-soluble compound, readily absorbable, and produces relatively little local injury. The product is supplied in the form of ampules containing 0.2 gm. of thio-bismol. Parke, Davis & Co., Detroit. (Jour. A. M. A., July 19, 1930, p. 200.)

FOODS

The following products have been accepted by the Committee on Foods of the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in Accepted Foods:

Heinz Rice Flakes Prepared with Pure Rice Cellulose (H. J. Heinz Co., Pittsburgh).—A flaked rice containing added rice cellulose, yeast, salt and milk sugar. Milled rice, rice cellulose (7 per cent of weight of rice), yeast (7 per cent), table salt (2.75 per cent), and milk sugar (0.5 per cent) are cooked, dried, flaked, toasted, cooled and packed. The product is a breakfast cereal containing indigestible cellulose that is claimed to be less irritant than wheat bran. It is proposed for use in an anticonstipative diet.

Ry-Krisp (Ralston Purina Co., St. Louis).—A whole rye grain wafer flavored with salt. Ry-Krisp may be

used in cases of wheat allergy. The wafers encourage thorough chewing.

Merrell-Soule Powdered Skim Milk (The Borden Co., New York).—A standard, uniform, practically fat-free, powdered skim milk. It contains fat 1.0 per cent, protein 36.5 per cent, lactose 51.8 per cent, mineral matter 7.9 per cent, moisture 2.5 per cent. The product is offered as a near approach to a fat-free milk.

Curtice Brothers Certified Nursery Foods (Curtice Bros. Co., Rochester, N. Y.).—Sieved spinach, carrots and tomato, and vegetable purée. The water content approximates that of the raw vegetables. These foods are stated by the manufacturer to be especially prepared for babies and young children. The manufacturer guarantees a declared minimum number of units of Vitamins A, B and C. This information is declared on the label of the cans.

Alp Rose Canned Foods (John Sexton & Co., Chicago).—These are canned fruits and vegetables, packed in water without added sugar or salt, and intended for use in restricted diets. The label declares the average composition for available carbohydrates, protein and fat.

Van Camp's Puréed Fruits and Vegetables (Van Camp Packing Co., Indianapolis).—These include purées of peas, spinach, tomatoes, prunes, apricots, carrots with puréed tomatoes and beef broth, and mixed vegetables with beef broth. These foods are designed by the manufacturer to influence the greater use of certain vegetables of good nutritional value. They are intended to provide them in smooth diet form and are chosen for their vitamin values. (Jour. A. M. A., August 16, 1930, p. 485.)

Sun Wheat Biscuits (Canada Biscuit Co., Ltd., London, Ont.).—A wheat biscuit with unusual vitamin and calcium content.

Sunwheats (The Sawyer Biscuit Co., Chicago).—Sunwheats is the brand name for Sun Wheat Biscuits manufactured for distribution in the United States.

Kiddie Kanned Vegetables, Fruits and Cereals (Kiddie Kanned Foods, Inc., Seattle, Wash.).—Canned cooked and sieved vegetable soup, oat porridge, wheat porridge, spinach, tomatoes, carrots, apples and peaches. They contain no added salt or sugar. To prepare these products the vegetables and fruits are washed, cooked under pressure to soften for sieving. The hot sieved foods are packen in cans, sealed and processed. Crushed oats and wheat are cooked under pressure, sieved, packed hot, and processed.

Horlick's Malted Milk Lunch Tablets (Plain and Chocolate Flavored) (Horlick's Malted Milk Corporation, Racine, Wis.).—These are Horlick's Malted Milk, plain and chocolate flavored, compressed into tablets. (Jour. A. M. A., September 20, 1930, p. 865.)

Horlick's Malted Milk (Horlick's Malted Milk Corporation, Racine, Wis.).—The product is a dried milk and extract of malted barley and wheat. Horlick's Malted Milk is claimed to be a nutritious food and when taken hot before retiring to be helpful for inducing sleep, and to be valuable in diets for undernourished, nervous patients, those afflicted with wasting diseases, invalids and convalescents.

Horlick's Sweet Chocolate Flavor Malted Milk (Horlick's Malted Milk Corporation, Racine, Wis.).—The product is Horlick's Malted Milk flavored with cocoa. Its composition is essentially that of Horlick's Malted Milk.

Grape-Nuts (General Foods Corporation, New York; Postum Co., Inc., Battle Creek, Mich.).—A breakfast cereal of whole wheat and malted barley. The manufacturer offers Grape-Nuts as an energy food providing proteins, the mineral elements of wheat and barley, and Vitamin B. (Jour. A. M. A., August 23, 1930, p. 595.)

ACCEPTED DEVICES FOR PHYSICAL THERAPY

The following have been accepted by the Council on Physical Therapy of the American Medical Association for inclusion in its list of accepted devices for physical therapy:

Austin's Irrigators.—Austin's Irrigators (W. D. Peattie, Inc., Cleveland, Ohio) are designed for "dilating the sphincter muscles" and "for continuous irrigations," particularly in "the use of extreme temperatures in (irrigating) liquids." It is claimed for the apparatus (1) that complete dilation and thorough cleansing is accomplished; (2) that the vaginal types permit long uninterrupted douching; (3) that the rectal types permit long uninterrupted irrigation; (4) that they are made of material which permits the use of irrigating liquids of high or low temperature; (5) that the apparatus may be taken apart and sterilized thoroughly; (6) that it is easily tolerated by the patient; (7) that any soluble antiseptic may be used; and (8) that the irrigators or tips can be made a part of any irrigating apparatus. The Council on Physical Therapy believes that these claims are reasonable and not unwarranted. (Jour. A. M. A., August 2, 1930, p. 343.)

Sorensen Therapeutic Inhaler No. 922.—The Sorensen Therapeutic Inhaler No. 922 (C. M. Sorensen Co., Inc., Long Island City, N. Y.) is stated to be an electrical instrument giving warm, dry air for the vaporization of inhalants. The device is constructed to heat air in sufficient volume to permit of deep and continued breathing direct from the applicators, thus providing the mucosa with a continuous supply of warm air or of warm medicated vapor. It is designed to operate on a 100 to 125 volts, alternating or direct current, and its power consumption is less than 15 watts.

Sorensen Therapeutic Heater No. 921.—The Sorensen Therapeutic Heater No. 921 (C. M. Sorensen Co., Inc., Long Island City, N. Y.) is similar to the Sorensen Therapeutic Inhaler. It is different in that the cold air, instead of being drawn through a heating chamber, is forced through by some type of air compressor. It is claimed to be of value in the treatment of those diseases of the middle ear where the application of warm, dry air, or warm medicated vapor, is indicated. (Jour. A. M. A., August 9, 1930, p. 413.)

Sunlit Ultraviolet Glass.—The window glass known as "Sunlit" (Semon Bache & Co., New York) is stated to be a glass that transmits the biologic ultraviolet rays of the sun. According to a test conducted by the Bureau of Standards this glass does transmit an appre-

ciable percentage of the solar rays which have been shown to have antirachitic properties. (Jour. A. M. A., August 16, 1930, p. 484.)

Maltese X-ray Lead Glass.—Maltese *X*-ray Lead Glass (Semon Bache & Co., New York) is a lead glass designed for *x*-ray protective shields. Measurements of the protective qualities of several samples were made by the Bureau of Standards and were satisfactory. (Jour. A. M. A., September 20, 1930, p. 865.)

The Davis Inhalator.—The Davis Inhalator (Bullard-Davis, Inc., New York) is a portable apparatus designed to assist physicians in the administration of oxygen or a mixture of oxygen and 5 per cent carbon dioxide in resuscitation in various forms of asphyxia. Compressed gases are contained in tanks and by a reducing valve may be delivered at the desired pressure through a breathing bag and mask as demanded by artificial or natural breathing of the patient. The apparatus meets the requirements for inhalators of approved standard and incorporates devices which make for flexibility, adaptability and safety. (Jour. A. M. A. July 19, 1930, p. 200.)

Comprex Electro-Cautery and Diagnostic Light (Comprex Oscillator Corporation, New York).—A device for cauterization by means of electrodes which are electrically heated to the desired temperature. The device consists essentially of a transformer, designed to operate on either a 110 or 220 volt, 60 cycle alternating current circuit. The transformer is also tapped at such point as will give the desired voltage for the operation of a diagnostic light.

"Stoppollen" Air Filter (Davies Air Filter Co., New York).—A simplified portable filter which delivers dust- and pollen-free air. The apparatus is described as consisting of a cabinet rectangular in shape, which contains the filter screen, a pressure fan and an electric motor, and is so constructed as to fit into any sized window. The cost of operating the device continuously for twenty-four hours is about ten cents. Tests were conducted which demonstrated that the Stoppollen air filter was efficient as a means of keeping a room free from dust and pollens. (Jour. A. M. A., May 31, 1930, p. 1760.)

Scillaren-B.—The amorphous component of the natural mixture of the glucosides occurring in squill, *Urginea maritima.* Completely dried scillaren-B contains approximately 99.5 per cent active glucosidal substance. Scillaren-B dried in a high vacuum at 78° C. for fifteen hours loses not more than 5 per cent of its weight. The actions and uses are the same as those of scillaren. It is administered intravenously when immediate action is imperatively indicated. Scillaren-B is marketed in the form of ampules each containing 0.5 mg. (1/130 grain) of scillaren-B. Sandoz Chemical Works, Inc., New York.

Ampoules Glucose (Dextrose, U.S.P.) Lilly, 50 Gm., 100 c.c.—Each ampule contains dextrose, U.S.P. (New and Non-official Remedies, 1930, p. 245), 50 Gm.; distilled water to make 100 c.c.; accompanied by an ampule containing 4 c.c. of a buffer solution. Eli Lilly & Co., Indianapolis.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

BOOKS RECEIVED FOR REVIEW

MINOR SURGERY AND BANDAGING. Gwynne Williams, M.S., F.R.C.S., Surgeon, University College Hospital. Twentieth Edition. 445 pages. Illus. Flexible binding, $3.50. Philadelphia: F. A. Davis Company, 1930.

HANDBOOK OF ANATOMY. James K. Young, M.D., F.A.C.S., Late Professor of Orthopedics, Graduate School of Medicine, University of Pennsylvania. Revised by George W. Miller, M.D., F.A.C.S., Associate in Anatomy, Jefferson Medical College. Seventh Revised Edition. 460 pages. Illus. Flexible binding, $3.75. Philadelphia: F. A. Davis Company, 1930.

EPISCOPAL HOSPITAL REPORTS. Volume VI. Edited by John H. Arnett, M.D., of Episcopal Hospital, Philadelphia. 460 pages. Illus. Cloth. Philadelphia: Press of Wm. J. Dornan, 1930.

TEXTBOOK OF PATHOLOGY. Edited by E. T. Bell, M.D., Professor of Pathology, University of Minnesota. 627 pages. Illus. Cloth, $8.00. Philadelphia: Lea & Febiger, 1930.

ARTERIAL HYPERTENSION. Edward J. Stieglitz, M.S., M.D., Assistant Clinical Professor of Medicine, Rush Medical College, University of Chicago. 280 pages. Illus. Cloth, $5.50. New York: Paul B. Hoeber, Inc., 1930.

OBSTETRICS. A text-book for the use of students and practitioners. J. Whitridge Williams, Professor of Obstetrics, Johns Hopkins University, Obstetrician-in-chief to the Johns Hopkins Hospital, Baltimore. Sixth edition, revised. 1157 pages. Illus. Cloth, $10.00. New York: D. Appleton & Company, 1930.

SELECTED READINGS IN THE HISTORY OF PHYSIOLOGY. Edited by John Farquhar Fulton, M.D., Sterling Professor of Physiology, Yale University School of Medicine, Baltimore, Md.: Charles C. Thomas, Publisher, 1930. Price $5.00.

A long need has been filled by Dr. Fulton's book. It is a type of book which seems to become more and more popular, judging from the success of works like E. R. Long's "Selected Readings in Pathology from Hippocrates to Virchow," and John Rurāh's "Pediatrics of the Past."

Dr. Fulton was fortunate in the choice of the arrangement, dividing the entire material into several large chapters according to subjects and arranging each chapter chronologically. Each chapter has a short but good introduction and every chosen part is preceded by a short biography of the author. The language is exquisite and the short but concise biographies are unsurpassed, describing in a few lines not only dry facts as to the life of the respective scientist but giving in brief an idea as to his main works and their effect on the progress of physiological thought. On every page the editor shows himself a scholar; he is most exact in giving the sources and—which increases the value of the book—is quite generous with reference as to authors and subjects. The translations and the use of technical terms are very good and Dr. Fulton can easily

take a chance on "holding himself responsible"; the same is true of the choice of illustrations and the print.

These "selected readings" are of much greater value than the average man is willing to admit before reading them. We have to realize that most of us have never seen the original texts of the most important findings in medicine, partly because they are in some language with which most of us are not acquainted, partly because the sources are rather difficult to secure, even in new editions. Here we have a selection of readings giving us the epoch-making findings in the progress of physiological knowledge, easy to read and arranged in a form to secure complete understanding.

Although one would like to see one or the other added selection in this book, especially in the chapters containing the physiology of the endocrine glands, it accomplishes its endeavors completely. This is not intended as any adverse criticism of this book—it is a sign of how one feels after reading it—one wants more.

ROBERT ROSENTHAL, M.D.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

POSITION WANTED: Young lady with two years' laboratory and *x*-ray experience wishes position in hospital, clinic or doctor's office. One year's experience in New York hospital. Also experienced stenographer. Address D-105, care MINNESOTA MEDICINE.

POSITION WANTED—*X*-ray, laboratory and physiotherapy technician desires position. Training received at Swedish Hospital, Minneapolis. Address Elinor Johnson, 639 East 17th Street, Minneapolis.

WANTED—Position in Twin Cities. Registered nurse, several years' experience. Qualified laboratory technician, also training in X-ray and physiotherapy. Address D-108, care MINNESOTA MEDICINE.

FOR SALE—Wonderful opportunity for surgeon. Eighteen room hospital. Operating room. Modern. Good practice, rich country. Building cost $21,000, priced $6,000. Small cash payment. Will send photo. Address Wallace King, Waverly, Minnesota.

WANTED—A well trained specialist, internal medicine, interested in joining a well established clinic group in Twin Cities. Scandinavian preferred, although not essential. Address D-106, care MINNESOTA MEDICINE.

WANTED—Position in or near Twin Cities. Graduate nurse, experienced in physiotherapy, hydrotherapy and massage. References. Address D-107, care MINNESOTA MEDICINE.

GOOD LOCATION—For medical doctor to share office with dentist. Address or call at 3754 Cedar Avenue, Minneapolis.

FOR SALE—Office and equipment. Excellent location at Lake and Hennepin, Minneapolis. Four room office suite well equipped. Leaving city. Good price for cash deal. Address D-109, care MINNESOTA MEDICINE.

VOL. XIII December, 1930 No. 12

SPINAL ANESTHESIA WITH REDUCED DOSAGE OF SPINOCAIN*

ARNOLD SCHWYZER, M.D.
Saint Paul

IT IS not our intention to discuss the value of spinal anesthesia, nor the advantages of spinocain (Pitkin) over other methods. Whoever has seen the perfect relaxation of the abdominal walls in a difficult operation in the upper abdomen readily recognizes the advantages of the method; but the fear of accidents has kept many surgeons from employing the method. The danger is, of course, proportionate to the dose of the anesthetic.

We simply want to mention, for the benefit of those who are using the method, a way of getting along quite well with considerably less spinocain than is generally given. The dose is hardly more than half of what we had to use formerly in order to obtain a satisfactory anesthesia. Spinocain is lighter than the cerebro-spinal fluid, and for this reason can, as it were, be floated to any position we desire, though the difference in specific weight of the spinocain (1.005) and of the cerebro-spinal fluid (1.007) is not great. Of course spinocain will diffuse rather rapidly and the novocain in it become fixed to the adjoining nerve tissue. For this reason it is desirable to bring it as rapidly as possible to the place where it is needed. The dorsal curve of the vertebral column, with the patient on his back, tends to bring the bulk into the lumbar arch. In order to reach the lower dorsal segments, the head of the table is raised. The anesthetic reaches the dorsal curve, and if the operation is to extend to the epigastrium the fifth or sixth root has to be reached. The ramus perforans anterior of the sixth thoracic nerve takes care of the sensation of the area about the base of the ensiform process, while the seventh supplies the region to the side of the ensiform. We ought to reach therefore the fifth root with our anesthetic because of the law of overlapping in the sensory distribution. If you look at the curve of the vertebral column of an individual lying on his back, you can readily see that sufficient tilting to cause the spinocain to float to the fifth nerve, or even only to the sixth or seventh, will allow it to escape toward the cervical spine, where it is not wanted and may cause trouble.

If you turn the patient onto the stomach, the dorsal curve allows you by proper tilting to bring the anesthetic to the exact spot desired. The head is kept low and the spinocain can not reach the cervical region before a considerable part of it has been fixed and only a small balance of novocaine has diffused. Looking over the back of the patient, with some horizontal line on the wall of the room as guide, one can readily make out the highest point in the dorsal curve. This is the whole trick. The spinocain thus does not go higher than we want it. It can therefore be injected undiluted with spinal fluid, and for this reason it will ascend more promptly before it is diffused and part of it fixed by nerve tissue. It will reach the desired upper levels in more concentrated form and it will above all strike the sensory and not the motor roots first. It will strike them posteriorly where they are still fine separate fibres. If we are to operate on the right side of the abdomen, the patient, after the spinal injection, is turned toward the stomach with the right shoulder higher than the left. If one operates on the left side, the left shoulder is made the highest spot. The fibres of this side then get the most direct anesthetic effect. Leaving out of consideration the anesthesia of the cauda equina, where turning on the stomach is of no value, it is evident that with the patient lying on the back the sensory thoracic roots re-

*Read before the Ramsey County Medical Society, St. Paul, Sept. 29, 1930.

ceive the anesthetic only after a certain amount of diffusion has reached the lateral areas of the spinal canal. This occurs after the motor roots and the cord surface have fixed part of the anesthetic. It has often happened since we have adopted the method of turning the patient toward

Fig. 1. Showing dorsal curve. Its apex is readily found by watching the horizontal lines on wall.

the stomach that we could start the operation while the patient could still wiggle the feet, though the abdomen was relaxed. In other words the spinocain ascended promptly after injection. With very small doses the relaxation was not perhaps always as complete as with the old way of turning the patient promptly onto his back. We usually leave the patient in the properly measured elevated position for about four or five minutes after the injection before turning him over on his back on the level table. By this time most of the novocain ought to be fixed to the neighboring nerve tissue. If doses larger than one ampoule are given, the patient after four and a half minutes of elevated position is tilted with the head low for half a minute before turning him on his back in order to counteract any undesired ascending of spinocain along the upper dorsal curve. I am, however, not sure that this is of any particular value after this lapse of time.

Let us repeat that it is here not our aim to make an appeal for spinal anesthesia in general nor even for spinocain, though we consider it a very important addition to anesthesia. Before I saw the beauty of a good spinocain anesthesia I had refused to take the risks of spinal anesthesia with my patients. Even now we are not sold on the spinal method. Since about the first of the year we have turned the patients over on the stomach after injection. Of 382 operations performed since January 1, 1930, 125 were done under local anesthesia, while spinal anesthesia was used in only 95 cases. In two additional instances spinal anesthesia was attempted but could not be carried out. These were not injected. In one of these the spinal canal was apparently entered but no fluid came and we did not repeat the maneuver; in the second case blood came.

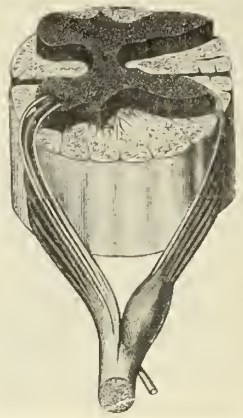

Fig. 2. Cross section of cord. Note the separate nerve fibres as they emerge from cord.

Among the ninety-five injections three were definite failures, probably due to too small a dose or to some faulty technic. The anesthesia was very insufficient. The other 92 anesthesias were considered satisfactory. Fourteen were marked as "reasonably good" on the chart and 76 as "excellent." In two cases I find no detailed notes. Among the cases judged as "reasonably good" there were instances of vomiting, or a return of sensation at the end of the operation. In four of these cases, to be mentioned later, the anesthesia had to be assisted by other means. It must be taken into consideration that at this time we were trying to find the smallest permissible doses. The site of preference for the injection in upper abdominal surgery is with us between the second and third lumbar vertebræ. Cerebro-spinal fluid is not withdrawn, especially if not more than one ampoule is given.

About four months ago the writer had acute appendicitis and the occasion was made use of in testing the method. My assistant, Dr. R. T. Muller, who performed about half of the anesthesias of the group of cases here presented (the other half having been done by the writer), injected 1.6 c.c. spinocain preceded by one and a half ampoules of ephedrin (Pitkin) subcutaneously. The usual preoperative morphine and atropine hypodermic was omitted. Apart from

the skin prick nothing was felt upon injection. I had to be told that the injection was completed. No paresthesia occurred. At times some patients had claimed they felt an itching at the start of the anesthesia. The operation was absolutely painless. At one time only, when some strong traction was made with a retractor, there was a gentle painless sensation of pulling downward on the skin in the region of the left nipple. The surgeons were emphatic in speaking of the complete relaxation of the abdominal muscles even when the peritoneum was lifted by forceps at the time of closure. About one hour after the injection sensation and motion started to return and were practically normal half an hour later. Painful spasms in the muscles of the back and abdomen on the right side had been present before operation and had somewhat blurred the issue. These persisted for several days after the operation. They re-appeared after operation with the restoration of nerve conduction and caused the patient to seek relief by getting up and sitting in an easy chair five hours after the injection. As the sitting posture relieved the spasms very much, several hours were thus spent in the chair reading a book. No untoward symptom followed the operation, no trace of nausea or headache, no afterpain except the normal moderate soreness in the wound.

In order to give a general picture of the nature of operations and the dose used we will group these 92 cases according to the dose of spinocain. The patients were all adults or at least 17 years of age.

The largest dose given was 3 c.c. This does not mean that it would not have been better to have given a little more in a very long operation, nor that some of the patients could not have gotten along quite well with less.

Cases	Spinocain
6	3 c.c.
7	2.75 c.c.
43	2 c.c.
36	less than 2 c.c.

Of these 36 cases receiving less than 2 c.c.

19 received	from 1.8 c.c. to 1.6 c.c.
14	1.5 c.c.
2	1.4 c.c.
1	1.33 c.c.

The six cases in which the maximal dose, i. e., *3 c.c. spinocain* was given, were the following:

One, a resection of the stomach with a large resection of the corpus pancreatis.

One, a very large hematoma retrocolicum the nature of which was unknown before operation.

One, gallstones with a cholecysto-duodenal fistula.

One, gallstones and appendicitis in a very large person.

One, gallstones and acute cholecystitis, also in a large person.

One, a gastro-jejunal ulcer.

The seven cases receiving 2.75 c.c. spinocain were:

3 cholecystectomies, two of them with acute cholecystitis, one with pericholecystitic abscesses.

2 cases of branched kidney stones.

1 a carcinoma (primary) of the Fallopian tube in a very large woman.

1 an acute perforation of a duodenal ulcer.

In 43 instances 2 c.c. spinocain (200 milligrams of novocain) were given:

1 an endothelioma of the pleura.

11 cholecystectomies (some with appendectomy).

1 a carcinoma of the pancreas; cholecystogastrostomy.

1 a carcinoma of the cecum; ileo-colic resection.

1 abdominal hysterectomy.

4 abdominal hysteromyomectomies.

6 appendectomies, acute or in interval; 3 of them with Watkins' operation for cystocele and perineoplasty.

4 abdominal hernias.

4 pelvic laparatomies, some combined with perineal work.

4 suprapubic prostatectomies.

5 Watkins' operation with perineoplasty (one with operation for bunions).

1 a post-anal dermal inclusion, acutely inflamed.

Less than 2 c.c. spinocain was administered to 36 patients. From 1.8 to 1.6 c.c. were given in the following 19 cases:

6 cholecystectomies (mostly with appendectomy).

3 diffuse peritonitis from appendicitis.

4 appendicitis.

1 carcinoma of ovary; large fixed mass, suture of ruptured sigmoid.

3 ovarian cysts.
1 carcinoma of leg after burn; excision and transplantation.
1 perineoplasty and hemorrhoidectomy.

1.5 c.c. spinocain was given in:

4 cholecystectomies.
1 gastrostomy.
2 double inguinal herniæ.
1 anus præternaturalis.
1 exploratory laparotomy in diffuse carcinomatosis of peritoneum.
1 cystoma ovarii malignum.
1 carcinoma of large myomatous uterus, grown into mesosalpinx (44 per cent hemoglobin).
1 appendectomy and perineoplasty.
1 cystoscopic dilatation of ureter in man.
1 curettage, perineoplasty and hemorrhoidectomy.

1.4 c.c. spinocain was given in:

1 carcinoma of rectum; excision. A little gas needed.
1 acute appendicitis gangrenosa. Excellent anesthesia.

1.33 c.c. spinocain was given in:

1 appendicitis subacuta. A little local anesthesia for the skin was added.

All the operations were done at St. Joseph's hospital except one of the cases of renal calculi, which was at the University hospital.

The patients to whom we gave more than one 2 c.c. ampoule almost all had lesions of the upper abdomen where a tedious operation was anticipated. Nevertheless you may have noticed that for instance among the 27 cholecystectomies there were 21 who had received at most 1 ampoule or even as little as 1.5 c.c. The case of endothelioma of the pleura received only 1 ampoule. In this instance the sixth, seventh, eighth ribs with the intervening structures of the chest wall had to be extensively resected and also a small area of the diaphragm where the tumor was adherent. The anesthesia was ideal. The ileo-colic resection was done with one ampoule and the anesthesia was all one could possibly wish. All pelvic work, herniæ among which were four very tedious postoperative abdominal herniæ with adherent intestines, appendicitis, acute or chronic, with or without free peritonitis, were never given more than 1 ampoule and very frequently less.

Similar cases were of course operated upon under general anesthesia, but if anything the more serious and tedious ones were chosen for spinal anesthesia.

With more experience the dose was gradually reduced. Among the last sixty cases of spinal anesthesia there were only four who received more than one ampoule (2 c.c.) of spinocain and among the last thirty-seven cases only eight had as much as 2 c.c. while the balance had often materially less.

In this list of ninety-two anesthesias which were classed as satisfactory there are, however, four instances where the spinal anesthesia alone was not sufficient. The first one of these was a resection of the stomach with a large resection of the middle portion of the pancreas. Three c.c. of spinocain were given. The operation took unduly long, lasting two hours and thirty-five minutes, and for the closing of the abdomen gas-ether was given. Up to that moment the anesthesia had been ideal. Another patient had received 1.7 c.c. for a cholecystectomy and appendectomy. When pulling on the cystic duct caused pain, gas was given for a few moments. The third case was an appendicitis where we tried the low dose of 1.33 c.c. Perhaps we started a little too soon with the operation; instead of waiting longer the skin was infiltrated with novocain. The fourth case was an excision of a carcinomatous rectum which was attempted with as little as 1.4 c.c. for trial. Less than half of the usual dose of gas was needed and no ether.

There were no untoward accidents, not even moments of apprehension in this group. Among the 95 patients operated upon under spinal anesthesia since January 1st, which includes the three unsatisfactory injections, there was one postoperative death—the carcinoma of the pancreas where a cholecysto-gastrostomy was done. It was not due to the anesthesia. The patient with his far advanced condition died a week after the operation in icterus gravis from terminal pneumonia. The number is of course far too small to give this statement any weight. But whatever the danger from spinal anesthesia may be it must be chalked up against spinal anesthesia in general, and not against the modification which consists of cutting this danger in half.

Before using our present modification we had a much larger percentage of instances where gas had to be added for a satisfactory anesthesia. This was undoubtedly mostly due to inexperi-

ence, but the doses over 3.25 c.c. spinocain caused at times apprehension which made the innovation of turning the patients over and thereby reducing the required dose by nearly one-half not only welcome to us but to several of our colleagues at St. Joseph's hospital who are emphatic in their statement as to the benefit they derived from this modification. Doctors W. C. Carroll, E. M. Jones, F. E. B. Foley, W. C. Rutherford, F. C. Schuldt, F. H. Neher, E. H. Norris and others have thus expressed themselves. Dr. Carroll started to use our modification soon after we did. He was emphatic as to the reduction in the dose of spinocain made possible by this method.

Dr. Foley uses our modification routinely at the Ancker (municipal) hospital in his urological service. He declares he has not had a failure since he adopted the procedure. The usual dose given was 2 c.c.

Dr. W. C. Rutherford states that by this manner of turning the patients over he can bring the anesthesia high enough for upper abdominal work without the apprehension he experienced previously, and that instead of giving 3 c.c. spinocain he can get along with 1.5 to 2 c.c.

Dr. Norris was converted to our procedure by an experience in a case of left sided inguinal hernia. Two c.c. of spinocain were injected while the patient rested on his left side. There was some delay in turning the patient on his back and he remained for five or six minutes on his left side. When he was finally placed on his back it was found that he had obtained perfect anesthesia on the right side of the abdomen, but almost none on the left. It was necessary to wait nearly fifteen minutes before the anesthesia appeared on the left side.

To sum up: We avoid mixing the spinal fluid with the spinocain by repeated withdrawals. We try to bring the undiluted spinocain as quickly as possible to the dorsal roots of the desired area. By this modification in the use of spinocain the dose can be reduced materially, the sensory roots getting the anesthetic directly in the least diluted form; the height of the anesthesia can be accurately arranged for, and the entrance into the cervical region (when it is not desired) is excluded, if we leave out of consideration a small amount of diffused novocain after most of it has been absorbed and fixed in the area where it was first brought to.

It would of course be very improper to try to raise this procedure to the dignity of a "method" and thus to somewhat lose sight of the real work done by Dr. Pitkin.

THE PRACTICAL VALUE OF EXAMINATION OF BLOOD SMEARS*

Charles H. Watkins, M.D., and Frank J. Heck, M.D.
Rochester, Minnesota

EXCEPT for an occasional differential count, examination of the blood smear has to a very large extent been discarded by most men in general practice. Although determination of values for hemoglobin and erythrocytes gives much information, still it is only through examination of the smears that information as to whether or not the bone marrow is active, and, if it is active, the extent of this activity, can be obtained. In primary types of anemia the percentage of reticulated erythrocytes has been used as an index of the response to treatment. In the renewed interest in secondary anemia which has arisen in the last five years, comparatively little attention has been paid to these features of activity of the bone marrow. The technic of examination of smears is relatively simple. Special training is not required, except for recognition of rare types of leukemia or of conditions in which immature cells are just beginning to appear in the circulation and are present only in small numbers. The physician in general practice can carry out every necessary procedure for the diagnosis of diseases of the blood, since this requires only the equipment which should be in every physician's laboratory.

In order properly to interpret the smears, it is necessary that the technical procedure be given consideration. One of the most important features is the correct making of blood smears. Satisfactory smears may be obtained by the following method:

Preparation of slides:

1. Place in glacial acetic acid for fifteen minutes.
2. Wash in distilled water.
3. Place in 95 per cent ethyl alcohol for five minutes.
4. Dry with clean towel.
5. Pass through flame of alcohol or Bunsen burner two or three times.

Making the blood smear:

1. Hold slide by edges and touch against drop of blood so that two or three small drops lie across one end of slide.
2. Place this slide on a flat surface.
3. Take another slide; place it on middle of lower slide at angle of 30°. Draw slide backward into blood and then push forward, distributing the blood evenly. Do not exert pressure; the weight of the slide is sufficient. To make a thick smear use a rapid motion; to make a thin smear use slow motion.
4. Whip slide rapidly through the air until dry.

Wright's stain is most widely used in this country. The greatest difficulty attendant on its use is to obtain satisfactory distilled water, since if the water is too acid or is alkaline, improper staining of both erythrocytes and leukocytes results. However, since the introduction of buffer solution[2, 3] this difficulty has been eliminated and staining with Wright's stain has become a simple procedure; buffer solution maintains a hydrogen-ion concentration which is little affected by the addition of small quantities of acid or alkali. The solution recommended is made up as follows: 6.63 gm. of acid potassium phosphate (KH_2PO_4) and 3.2 gm. of dibasic sodium phosphate ($Na_2HPO_4.2H_2O$). These amounts are dissolved in 1,000 c.c. of the distilled water that is to be used.

Wright's stain is prepared by grinding 0.3 gm. of the dry stain in 100 c.c. of acetone-free absolute methyl alcohol. There are several satisfactory brands of the stain, already in solution, on the market. The technic of staining may be summarized as follows: Place 25 to 30 drops of Wright's stain on the blood film and allow it to stand one minute. Add an equal number of drops of buffer solution and allow the mixture to remain four minutes. Wash with distilled water and dry between blotting paper. If this technic is followed, an

excellently stained slide is almost invariably obtained. It is unnecessary to change the time of staining with various lots of stain.

One of the most accurate indexes for determining the activity of the bone marrow is estimation of the percentage of reticulated erythrocytes. Reticulation is the result of a chemical reaction between a vital stain and the undifferentiated spongioplasm of the erythrocyte. Brilliant cresyl blue is the vital stain which is most commonly used in demonstrating this reaction. There are many methods in use, but the following has been found satisfactory for routine work. A small drop of freshly drawn blood is placed on the end of a clean slide. To this is added a small drop of saturated aqueous solution of brilliant cresyl blue, and the two are then thoroughly mixed with a clean glass rod. A smear is then made in the same manner as that employed in making the ordinary blood smear, and this is counterstained with Wright's stain. The number of reticulated cells in 1,000 erythrocytes is then determined and the percentage of reticulated erythrocytes present is calculated. Since reduction of the size of the field facilitates counting, we use a metal disk with a small aperture. Normally the percentage is between 0.5 and 1.5 per cent. Increase in the proportion of reticulated erythrocytes indicates hyperactivity of the bone marrow whereas decrease indicates lack of proper activity. The reticulated erythrocyte count is of particular value in determining the efficacy of treatment in severe cases of pernicious anemia. On adequate treatment, the response of reticulated erythrocytes reaches a maximum between the eighth and twelfth days, and by the thirtieth day it usually has returned to normal.

Before considering the more significant morphologic features of the cellular elements in primary and secondary diseases of the blood, a word should be said regarding the degenerative and regenerative signs as seen in the erythrocytes. Of the features of degeneration, the following are the most important: (1) hypochromasia, in which decrease in the hemoglobin in the erythrocyte, results in a uniformly pale cell, and (2) poikilocytosis in which erythrocytes are irregularly shaped; pear-like shapes and club-like shapes are most common. The most important signs of normal or physiologic regeneration are (1) reticulation of erythrocytes which has been described; (2) polychromatophilia in which the erythrocytes still retain sufficient basophilic spongioplasm to give a bluish or greenish tint to the cytoplasm when the cells have been stained with

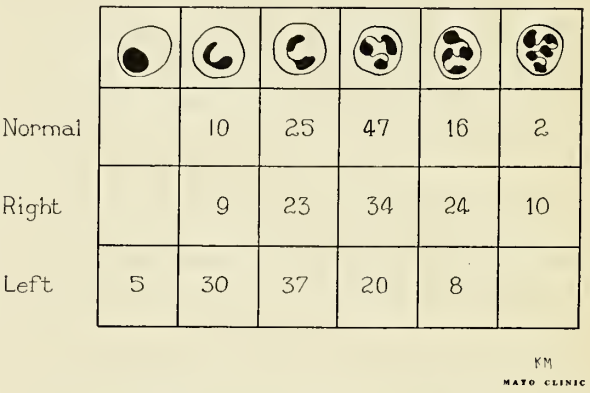

Fig. 1. Lobation of nucleus of the neutrophil with percentage of cells found in the normal, in a left shift and in a right shift.

Wright's stain; (3) anisocytosis in which there is variation in the size of cells, particularly of macrocytes and normocytes; (4) the presence of normoblasts, which are nucleated erythrocytes of varying degrees of immaturity, and (5) the presence, in some cells, of a single Howell-Jolly body, which is a pinkish-staining, rounded body, representing a remnant of the parachromatin of the nucleus after the chromatin has been dissolved in or extruded from the cell. The more important signs of pathologic regeneration are (1) basophilic stippling, which is due to precipitation of the basophilic spongioplasm by a circulating toxin; (2) the presence of megaloblasts, which are immature, nucleated cells of the primitive generation of erythrocytes; (3) the presence of multiple nuclear buds, which are evidences of beginning karyorrhexis in the nucleated erythrocyte, and (4) multiple Howell-Jolly bodies.

In addition to a study of the structural changes of the erythrocytes, morphologic study of the leukocytes is of great importance, particularly in regard to lobation of the nucleus of the neutrophilic leukocyte. Other morphologic changes in the leukocytes, such as those produced by toxicity, cannot be considered in a paper of this scope. In recent years, the terms "Schilling count," or "right

shift" and "left shift," have received considerable mention in the literature. This is best shown in Figure 1, which illustrates the distribution of the cells according to the number of lobes in the nuclei of the neutrophilic leukocytes. One distribution is that found in the blood of a normal person. Another distribution is that found in the blood of a patient who had a condition which occasioned a shift to the left; that is, an increase in the proportion of neutrophilic leukocytes of which the nuclei had a small number of lobes. The third distribution illustrated is that found in the blood of a patient who had a condition which occasioned the opposite picture, or a shift to the right. The shift to the left is seen in many conditions, particularly in infections, and is regarded as an indication of immaturity of the cell, or of the effect of a toxin on the chromatin in the nucleus. The degree of change from the normal is used as a diagnostic as well as prognostic sign.

In the study of secondary types of anemia, two important procedures are essential. One is elimination of the presence of organic disease, particularly of obscure organic disease. One condition which should be emphasized is chronic loss of blood from the gastro-intestinal tract. As has been pointed out by Giffin and Watkins, this has been associated with carcinoma of the stomach, duodenal ulcer, malignant growths of the small bowel, inflammatory lesions and benign ulcer of the small bowel, benign ulcer of the cecum, and polyps of the colon. In addition to elimination of organic disease, a clinical classification of chronic secondary anemia is essential. The types of anemia secondary to known organic disease or hemorrhage obviously are not considered. Giffin and Watkins have suggested a clinical classification of obscure types of secondary anemia. The types they recognize are those due to chronic hemorrhage, obscure malignant growths, chronic infection, dietary and other deficiencies and, in addition, a type in which the anemia at present must be regarded as indeterminate or idiopathic.

We have followed the morphologic classification of Watkins. The great majority of cases of idiopathic secondary anemia fall into two groups. In the first group, there is a proportionate reduction in the value for hemoglobin and the number of erythrocytes, giving a color index of approximately one. Morphologically, for the most part the erythrocytes are well filled with hemoglobin. If the reticulated erythrocytes are increased in number, and polychromatophilia and anisocytosis of macrocytes and normocytes predominate, the bone marrow is hyperactive and the anemia is probably due to chronic loss of blood or destruction of blood. If, on the other hand, there is predominance of degenerative features, such as poikilocytosis, anisocytosis evident by the presence of normocytes and microcytes, lack of regenerative activity, and low proportion of reticulated erythrocytes, it is obvious that there is hypofunction of the bone marrow. Treatment of the latter type of anemia should be directed toward stimulation of the bone marrow. In the second group there is reduction in hemoglobin and normal or nearly normal erythrocytes, giving a low color index. The percentage of reticulated erythrocytes is normal or slightly increased. Morphologically the outstanding feature is the hypochromasia of the erythrocytes, the cells having a pale, washed-out appearance. There may also be slight polychromatophilia and anisocytosis of the regenerative type. The leukocytes, as a rule, appear normal. In this type of anemia production of cells appears to be normal; the dysfunction is in the synthesis of hemoglobin. Whether or not the type of treatment can be determined by examination of the smears is yet to be shown. However, it seems reasonable that one should endeavor to supply the elements considered necessary in the synthesis of hemoglobin.

Although most cases of pernicious anemia may be diagnosed clinically, morphologic study of the blood is of great value, for in our experience certain features, when present, are diagnostic. The erythrocytes give evidence of generalized macrocytosis. The individual cells stain more deeply than normal, due to increased thickness of the cell and not to increased hemoglobin per unit of cell, as has been suggested by many authors. Other features, which may or may not be present, are polychromatophilia, anisocytosis, nucleated erythrocytes (both normoblasts and megaloblasts), basophilic stippling, and Howell-Jolly bodies. One of the most characteristic fea-

tures of the blood picture is found in the neutrophil. There is increase in the number of lobes of the nucleus, associated with thinning and stranding of the individual lobes. With macrocytosis and definite increase in lobation of the nucleus of the neutrophil, together with thinning and stranding of the individual lobes, there can be but little doubt that one is dealing with pernicious anemia. These changes do not necessarily hold for all stages of the disease, since there may be few signs, when the blood is nearly normal, or when the patient is under treatment.

In direct contrast to the picture seen in pernicious anemia is that of hemolytic jaundice. Here there is generalized microcytosis, with many of the cells spherical. The spherical microcytes are recognized by the absence of the pale center such as is seen in the normal, biconcave erythrocyte. In addition to these features, there is almost always marked regenerative activity, as is seen by increase in the proportion of reticulated erythrocytes, as well as by the other signs of physiologic regeneration, and especially by the presence of occasional large oval macrocytes. Naturally, the amount of regenerative activity noted is dependent on the stage of the disease and the degree of anemia. From recent observations it seems possible that there may be a form of hemolytic anemia in which the features just named may not be present.

There are three conditions in which study of the blood is the most valuable single diagnostic aid: (1) aplastic anemia, (2) leukemia, and (3) infectious mononucleosis. Persistently low percentages of reticulated erythrocytes or their absence, lack of other signs of regeneration of erythrocytes, and leukopenia with a high proportion of lymphocytes, are practically characteristic of aplastic anemia. Repeated examinations of the smears should be made before arriving at any definite conclusion.

The morphologic characteristics of the cells in acute and in chronic leukemia may be considered together. The outstanding features are varying degrees of immaturity of the leukocytes. Depending on the degree of immaturity, as well as on the proportion of immature cells to mature cells, the forms of leukemia may be classified into two types. In the acute type, the myeloblast or stem cell predominates; in chronic types, the mature cells are in the majority, but a small proportion of immature cells is present, some of which may be stem cells. It must be emphasized that not all cases of leukemia are associated with an increased number of leukocytes. Normal counts or leukopenia may be observed in association with acute types of leukemia, particularly in the acute types of leukemia of childhood. In a few cases in which there is leukopenia at the onset of the disease leukocytosis develops later.

Infectious mononucleosis is known under a variety of other names, such as acute benign lymphadenosis, benign lymphocytosis, or glandular fever. Since, clinically, this disease simulates leukemia in many respects, study of the smears is of particular importance. The characteristic feature of the blood is the maturity of the lymphocytes. Many of the atypical forms vary in size, form of nucleus, and staining reaction. Leukocytoid forms are frequently seen. One outstanding feature of the nuclei of these cells is the gradual transition between the chromatin and parachromatin which is so characteristic of the mature lymphocyte. As mentioned before, study of the smears over a period of some time is necessary to establish the diagnosis.

Purpura hemorrhagica may be confused with aplastic anemia and acute leukemia. Examination of the blood smear from a patient with purpura hemorrhagica distinguishes this condition from acute leukemia by the absence of immature leukocytes. The presence of reticulated erythrocytes and other regenerative signs characteristic of activity of bone marrow distinguish it from aplastic anemia. A normal differential count is the rule, rather than leukopenia and the high proportion of lymphocytes seen in aplastic anemia.

Agranulocytic angina is another condition in which a morphologic study of the blood smear, although not diagnostic, is of value. By daily examination of the smears there is found progressive decrease in the proportion of neutrophilic leukocytes. In those cases which end fatally, there is generally decrease in the number of lymphocytes toward the termination of the illness.

SUMMARY

The most important morphologic features of the blood in secondary anemia, and the more common forms of blood dyscrasia have been briefly considered. Morphologic examination of the blood should not be used as an absolute diagnostic criterion, but should be regarded as a valuable diagnostic and clinical aid.

COAGULATION CONDITIONS AND BACTERIAL EFFICIENCY OF PRELIMINARY WATER TREATMENT

The United States Public Health Service has recently announced the results of certain experimental studies relating to coagulation conditions and bacterial efficiency of preliminary water treatment. The studies recorded in this report are concerned with the effects of (a) the period of sedimentation, (b) the method of applying coagulant to the raw water, (c) the hydrogen ion concentration of the coagluation reaction, and (d) the density of coagulant added to the raw water, on the bacterial efficiency of coagulation-sedimentation as a preparatory treatment of water for rapid sand filtration and, incidentally, on the efficiency of the entire process of rapid sand filtration.

The experiments were carried out during portions of the three years, 1926, 1927, and 1928, at a fully equipped experimental rapid sand water filtration plant of 160,000 gallons daily capacity, designed to typify, as nearly as possible, current large-scale practice in this process of water purification, but with certain additional features incorporated in the plant for experimental purposes.

The results of the study yielded the following main conclusions:

(1) Substantial gains in the bacterial efficiency of coagulation-sedimentation resulted from prolongation of the nominal sedimentation period up to 8 or 9 hours, and measurable gains with periods up to 12 hours.

(2) Variations in the hydrogen ion concentration in the coagulation reaction from 5.6 to 6.9 produced little effect on the efficiency of coagulation-sedimentation. The efficiency became sharply diminished, however, with hydrogen ion concentration values exceeding 7.0 and slightly improved with hydrogen ion concentration values approaching 5.5.

(3) The bacterial efficiency of double-stage coagulation, with two separate stages of sedimentation, was consistently greater than that of single-stage coagulation with one stage of sedimentation. The observations indicated, however, that with the same total amount of coagulant and the same total period of sedimentation, little if any difference was observable between the results shown by double-stage and single-stage coagulation when carried out in conjunction with two separate states of sedimentation.

(4) A fairly consistent relation was shown between the amounts of coagulant added to the raw water and the resulting bacterial efficiency, both of coagulation-sedimentation and of this state in conjunction with filtration. This relationship was found to hold irrespective of raw-water turbidity or bacterial content, though it was more apparent when the turbidity and bacterial numbers were higher. Measurable gains in efficiency were shown with increases in coagulant density ranging up to 5 grains per gallon.

The general conclusion reached from the foregoing series of experiments was that the bacterial efficiency of rapid sand filtration processes can be increased very materially by means of longer periods of sedimentation and larger amounts of coagulant than ordinarily are used in current water purification practice. The economical limit of sedimentation appears to be reached somewhere between 8 and 12 hours, with little gain in efficiency beyond the upper limit of time stated.

FURTHER OBSERVATIONS ON THE TREATMENT OF PERNICIOUS ANEMIA WITH GASTRIC TISSUE OF SWINE*

H. Milton Conner, M.D.
Rochester, Minnesota

In November, 1929, I presented at the meeting of the Minnesota Society of Internal Medicine the results of feeding gastric tissue of swine to patients who had pernicious anemia.[1] In all cases there was increase in the numbers of reticulocytes, followed by increase in the number of mature erythrocytes and in the values for hemoglobin. The number of leukocytes also was increased in most instances.

Feeding of gastric tissue was suggested by the work of Castle and Loche, who gave muscle meat to a normal subject and, after they had caused the subject to vomit, they gave the vomitus to patients who had pernicious anemia. They thus brought about improvement in blood and symptoms, such as occurs after treatment with liver. My demonstration that approximately 26 per cent of a large series of blood relatives of patients who had pernicious anemia lacked free hydrochloric acid in the gastric content served further to fix attention on the stomach as a possible etiologic factor in the disease. Also, the well known fact that practically all patients who have pernicious anemia lack free hydrochloric acid in the gastric content suggested that the stomach was in some way connected with the etiology of the disease, and that the feeding of gastric tissue might supply some unknown element lacking in the stomachs of patients who have the disease. While my method of administration and preparation of the material was being perfected and any possible harmful effects of feeding the raw material were being investigated, Sturgis and Isaacs, and Sharp reported the results of independent work with desiccated stomach. Since then Wilkinson has reported work also done independently with raw and dried gastric tissue.

My results with raw and dried stomach were in all respects similar to those reported by Sturgis and Isaacs, and by Sharp, so that I was able to corroborate their work at an early date. Wilkinson's work with raw and dried gastric tissue gave results of a similar nature. In six cases which I reported[2] in November, 1929, the results were similar to those obtained by feeding liver or its extract. Because of the unfavorable age of the patients treated and because when most of the patients started treatment the number of erythrocytes was relatively high, the average increase was not quite so high as is found in the average patient treated with liver or its extract. The average increase in number of erythrocytes in the group of six patients was approximately 1,000,000 in an average of twenty-seven days. The number of reticulocytes, generally accepted as a criterion of regeneration of erythrocytes, increased in one instance to 35.6 per cent of the total number of erythrocytes, and the highest percentage of reticulocytes obtained in the individual cases reached an average of 11.7 per cent.

My conclusion, at that time, was that the material had an effect on the blood and the symptoms of patients who had pernicious anemia similar to that of liver or its extract. Since that time I have carefully observed thirty-five other patients in the hospital and have fed various preparations of raw and dried gastric tissue. My results with these additional cases amply corroborate the view expressed in the earlier paper, that the effect is similar to that obtained with liver or its extract, and this was also the view of Sturgis and Isaacs, of Sharp, and of Wilkinson.

Among patients whose erythrocytes numbered less than 2,000,000 in each cubic millimeter of blood (Table 1) when treatment was instituted, the number increased from an average of 1,450,000 to an average of 2,920,000 in twenty-three and fifty-eight hundredths days, or 432,000 each week. Among those who started treatment when the number of erythrocytes was more than 2,000,000 in each cubic millimeter of blood (Table 2) the number increased from an average of 2,710,000 to 3,570,000 in twenty-two and ninety-four hundredths days, or 292,000 each week.

*From the Division of Medicine, The Mayo Clinic, Rochester, Minnesota. Read before the Minnesota State Medical Association, Duluth, July 14 to 16, 1930.

40	5	75	3.34	80	3.73
41	11	73	3.00	75	3.22
Average	22.94	59.3	2.71	72.7	3.57

The number of reticulocytes increased in all cases, reaching a maximum of 65.8 per cent in one case.

There has been the same improvement in general symptoms that was reported in the earlier paper. The neurologic symptoms responded well in some instances but not in all. The minor neurologic symptoms usually have improved or disappeared, but in the more advanced cases the patients have been less responsive to treatment.

In most instances the stools were examined for parasites before and after treatment to avoid overlooking possible transmission to the patient of a parasitic disease by the use of the raw material. Disease has not been transmitted in any known instance.

As a result of the treatment of these additional cases I feel safe in asserting that the results with feeding of gastric tissue are similar to and apparently equal to those obtained with liver or its extract. Presentation of detailed study of these cases would be voluminous and must be reserved for another contribution.

TREND OF MENINGOCOCCUS MENINGITIS IN THE UNITED STATES

At a recent conference of State and Territorial Health Officers with the Public Health Service, it was pointed out by representatives of the Service that reports received from State Health Officers for the past five years indicate that there has been a progressive increase in the number of cases of meningococcus meningitis that have been recorded. It is true that the actual number of cases are not large when compared with the total population. It is significant, however, that each year there has been an increase over the preceding year, and that this rise has been continuing for five years.

When the prevalence of meningococcus meningitis increased during the period of 1915 to 1917, the number of cases rose in Europe before the movement occurred in the United States, but after the World War the number of cases did not rise noticeably in Europe until 1929, and then the increase was not general and the rates were not high.

Incomplete reports for the first three months of 1930 show rates higher than the normal for England and Wales, Scotland, The Netherlands, and Poland, but no figures from Europe have been found indicating a general increase in the prevalence of this disease comparable with that in the United States.

There was an outbreak of meningococcus meningitis early this year in the Anglo-Egyptian Sudan, and reports from the French Protectorate of Morocco show some increase in cases in March. Recent reports from Asia do not show anything unusual in the prevalence of the disease. Canada has reported comparatively few cases, but there has been a slight increase in incidence in Mexico.

The nomenclature relative to meningococcus meningitis has been changed several times, the disease having been variously designated cerebrospinal meningitis, epidemic meningitis, and other similar terms. For this reason earlier figures are not exactly comparable with the later ones.

The total number of cases of meningococcus meningitis reported throughout the United States for the past five years is as follows:

Year	Cases
1925	1,859
1926	2,226
1927	3,204
1928	5,781
1929	9,660

In considering these figures the difficulties of obtaining accurate reports should be borne in mind.

Since March, 1930, the reported prevalence of meningococcus meningitis in the United States has been lower than it was in the corresponding months of 1929.

THE INTRAVENOUS ADMINISTRATION OF SODIUM ISO-AMYL-ETHYL BARBITURATE (SODIUM AMYTAL) FOR THE ALLEVIATION OF PAIN DURING LABOR

A REPORT OF FORTY-SIX CASES

James J. Swendson, M.D.*
Saint Paul

MANY drugs have been used for the alleviation of pain during labor. All of them have failed in a greater or lesser degree to fulfil the requirements of an ideal anelgesic and anesthetic, namely, that pain shall be abolished or greatly alleviated; that the course of labor shall not be interfered with or prolonged; that the mother shall not be harmed; that the baby shall not be harmed.

The pharmacologic actions of the barbituric acid derivatives in animals and in man have given promise that one or more of them might be of value in obstetrics, and several reports have been made of their use. Cleisz[1] reported favorably on the intravenous administration of somnifene (diethyl-allyl-iso-propyl barbiturate of diethylamine) during labor. Delmas and Roume[2] reported unfavorably on their experience with the same drug. More recently Robbins et al.[3] reported on the administration of sodium amytal (sodium iso-amyl-ethyl barbiturate) in one hundred cases of labor, mostly by the intravenous route. Drabkin et al.[4] reported the use of the same drug administered rectally in thirty-three obstetrical patients.

The intravenous route of administration of sodium amytal was chosen in this series of cases. It is less painful than intramuscular administration. The patient obtains immediate relief from labor pains. The variable factor of intestinal absorption is eliminated. Furthermore, the effect of the drug is noted instantly and, Weiss[5] having pointed out that there are marked individual variations in the response of patients to identical doses, a suitable dose can be more accurately determined during administration.

The use of drugs other than sodium amytal was avoided in this series. Exceptions to the rule are noted in the tables. Toward the end of the second stage, however, small doses of pituitrin were occasionally given and 1 c.c. of pituitrin was given intramuscularly at the beginning of the third stage followed by 1 c.c. of ergot intramuscularly as soon as the placenta had been delivered.

The drug was supplied† in pyrex ampules containing either 0.5 or 1.0 gm. (7½ or 15 gr.). Immediately before administration, it was mixed with sterile distilled water from an accompanying ampule to make a ten per cent solution, which was clear in one to three minutes. It was advised that solutions not clearing in five minutes and having an opalescent appearance indicating the presence of colloidal material be discarded. All solutions used in this series, however, cleared promptly.

When a patient was in active labor and rectal examination revealed 3 cm. dilatation of the cervix, she was told that she would be given relief from pain at any time that she desired. The solution was then injected intravenously at the rate of 1 c.c. (0.1 gm. or 1½ gr.) per minute in doses of .250 gm. (3¾ gr.) to .666 gm. (10 gr.), the patient usually being asleep by the time 3 or 4 c.c. had been administered. A first dose of 0.5 gm. (7½ gr.) was found to be most effective for a woman weighing about 68 Kg. (150 lbs.).

When signs of returning consciousness, such as complaint of increasing pain or rational responses to questions, were noted, a second and even a third dose of the drug varying from .333 gm. (5 gr.) to .500 gm. (7½ gr.) was administered. The drug was also repeated for increasing restlessness, without, however, any lasting quieting effect being observed. The average interval between doses, when the drug was repeated once or twice during the labor, was two and one-third hours. The longest interval was seven hours, and the shortest, one-half hour. The average interval from the time of the first administration of the drug to delivery was four

*From the Earl Clinic, St. Paul, Minn.

†I am indebted to Eli Lilly and Company for supplying the drug used in this study.

hours in thirty-two primiparæ and two hours in fourteen multiparæ. The longest interval was ten hours, and the shortest, fifteen minutes.

A total dosage as high as 1.233 gm. (18½ gr.) was given during one labor. A subsequent determination of dosage in relation to body weight in twenty-four cases showed that .003 gm. (1/20 gr.) to .007 gm. (1/9 gr.) per Kg. in one dose produced varying degrees of analgesia and amnesia; and that .007 gm. (1/9 gr.) to .009 gm. (1/7 gr.) per Kg. in one dose produced complete amnesia for two to three hours.

Amnesia in twenty-six (70.3 per cent) of the thirty-seven cases which received 7½ gr. or more was classified as complete from the time of administration until immediately after delivery. Most of the patients then regained consciousness, although several of them had amnesia lasting one or two hours after delivery. Eight patients (21.6 per cent) were classified as having partial amnesia. Two of these patients (case 16, table 1 and case 33, table 2) had complete amnesia lasting for three hours after administration, when they regained consciousness and the drug was not repeated. Three others (cases 39, 40 and 45, table 2) had complete amnesia for one and three-fourths to two and one-half hours before delivery. One patient (case 38, table 2), a nervous primpara who received 7 and 6 gr. six and one-fourth and four hours before delivery, and in whom good amnesia was noted, afterwards stated that the labor had been very painful. Three patients (8.1 per cent) had slight amnesia. Patients who appeared to be conscious were questioned as to pain and were asked to remember numbers. The day following delivery they were asked to recall the numbers and were questioned concerning events of the labor, usually with little or no remembrance of what occurred after administration of the drug. Some of them remembered such incidents as being moved from bed to a wheel cart or to the delivery table. All patients, including those who had partial amnesia, were disoriented as to time. Most of the patients, including all of the multiparæ, were enthusiastic about the relief obtained.

The character of contractions during the first stage was not noticeably affected by the drug except in one case in which the administration of 5 gr. to a patient who had been in labor ten hours, immediately stopped contractions, which were resumed two hours later, the patient then delivering in one hour (case 3, table 1). In several patients, voluntary efforts during second stage contractions were not noted, but these cases terminated spontaneously without apparent delay. In five patients (cases 16, 18, 24, 25 and 29) to whom the drug was administered late in the second stage, termination of labor seemed to be hastened. The average duration of labor in thirty-two primiparæ was fifteen hours, in fourteen multiparæ, nine and one-fourth hours.

Eleven patients (24 per cent) of the entire series were extremely restless soon after administration of the drug and it was necessary to restrain them during contractions. One patient became maniacal and walked about the room in spite of forcible attempts to restrain her. Six patients (13 per cent) were moderately restless, and six (13 per cent) were slightly restless. Restlessness was usually present only during contractions or when the patient was disturbed. It was the most objectionable result of the procedure, for the patients who were restless required constant watching by nurses and were difficult to control during examinations and preparation for delivery, although they were quickly quieted by small amounts of an inhalation anesthetic after being taken to the delivery room. No relationship could be determined between the degree of restlessness and the depth of amnesia, the most restless patients having no memory of the labor or of their actions.

In all but six cases of the entire series, an inhalation anesthetic was administered at the time of delivery or toward the end of the second stage (see tables). It was noted that smaller amounts of the anesthetic were required than usual, and that the restlessness was readily controlled. The six patients who received no supplementary anesthetic were quiet during delivery, and some of them had episiotomies performed or lacerations sutured without remembering either the delivery or the perineal operation.

In seventeen cases in which the mothers' blood pressure was recorded before and after administration, nine cases (52.9 per cent) showed an average increase of 12 mm. of Hg., the greatest increase being 26 mm. and the least 2 mm.; five cases (29.4 per cent) showed an average decrease of 11 mm., the greatest decrease being 26 mm. and the least 2 mm.; and three cases (17.7 per cent) showed no change. In eighteen cases in which the pulse was recorded immediately be-

* Morphine sulphate gr. 1/6 1¼ hours before delivery.

** Amnesia complete for the first 3 hours.

† Baby was 3 weeks premature, weighing 5 lbs. 10 oz., and delivered ODP persistent. Morphine sulphate gr. ¼ 3½ hours before delivery.

†† Amnesia complete after the second dose in cases No. 39 and 40, and after third dose in case No. 45.

‡ A third dose of 5 gr. was given 1½ hours before delivery in case No. 43, and a third dose of 6 gr., 3 hours before delivery, in case No. 45.

‡‡ Mother had a severe pre-eclamptic toxemia.

fore, and at intervals after administration and until delivery, ten cases (55.5 per cent) showed an average increase of 12 beats per minute, the greatest increase being 28 and the least 5; three cases (16.7 per cent) showed an average decrease of 8, the greatest decrease being 10 and the least 4; and five cases (27.8 per cent) showed no change. In ten cases in which the respirations were recorded before and after administration, three cases showed an average increase of 7 per minute, varying from 4 to 12; two cases showed a decrease of 4 and 6; and five cases showed no change. The changes in blood pressure, pulse and respiration were, obviously, those common to normal labor. There was no suggestion of the decreased blood pressure, the moderately increased pulse, and the reduced rate of respiration constantly observed by Weiss[5] in patients with acute poisoning due to barbituric acid derivatives.

Postpartum observation disclosed no increase in bleeding, no restlessness after delivery, no increase in the incidence of nausea and vomiting. The patients were drowsy for several hours after delivery. Upon regaining consciousness, they did not complain of fatigue, although the striking well-being of patients following the administration of scopolamine-morphine analgesia was not observed.

The effects of the drug on the mothers in the thirty-seven patients who received 0.5 gm. (7½ gr.) or more of sodium amytal were summarized and evaluated, taking in consideration the following factors: (1) completeness of amnesia; (2) degree of restlessness; (3) interference with the progress of labor. In twenty-one cases (56.8 per cent), the results in the mother were classified as excellent; in nine cases (24.3 per cent), the results were good; in three cases (8.1 per cent), fair; in four cases (10.8 per cent), poor.

In nineteen cases in which the fetal heart tones were observed before and after administration of sodium amytal, eleven cases (57.9 per cent) showed an average increase of 12 beats per minute at some time before delivery, the greatest increase being 22, and the least 4; three cases (15.8 per cent) showed an average decrease of 17 beats per minute, the greatest decrease being 22, the least 10; and five cases (26.3 per cent) showed no change. These changes were considered to be well within normal limits.

Resuscitation of the babies was necessary in fifteen out of the forty-six cases (32.6 per cent). Of these, eight babies (17.4 per cent) were only slightly apneic and breathed after clearing the air-passages and rubbing the back; five (10.9 per cent) were moderately apneic and were given alpha-lobeline intramuscularly, after which breathing quickly became established. The apnea seemed to be due to an increased sluggishness of the respiratory center, for when breathing had once been established following stimulation, most of the babies cried lustily. Two babies (4.3 per cent) were asphyxiated and, in addition to drug stimulation, required tubbing before they breathed. One of the asphyxiated babies (case 38, table 2) was a premature infant who delivered O D P persistent; the other was delivered by a moderately difficult mid-forceps operation (case 41, table 2).

The average loss of weight after birth in the twenty-four cases recorded in table 2 was 6.8 ounces. Three babies who delivered spontaneously and weighed from 8 pounds 9 ounces to 9 pounds 7 ounces at birth, each lost 13 ounces. The average time during which weight loss occurred in the twenty-four cases was 3.4 days. All babies were given complementary feedings until and unless the mother's milk supply was adequate. Fifty per cent of them had regained their birth weight when discharged from the hospital on the ninth to the twelfth days. No relationship could be established between difficulty in resuscitation and weight change. No babies were sleepy and unable to nurse for several days after delivery as noted by Delmas and Roume[2] with their use of somnifene.

SUMMARY

The slow intravenous administration of freshly prepared, clear, ten per cent solutions of sodium amytal in doses of .500 gm. (7½ gr.) to .666 gm. (10 gr.) to thirty-seven women of a series of forty-six, after labor had become well established, produced analgesia and amnesia for periods of two to three hours. When the drug was repeated in doses of .333 gm. (5 gr.) to .500 gm. (7½ gr.) at average intervals of two and one-third hours until delivery, satisfactory amnesia was produced in all but 8.1 per cent. One-fourth of the patients were somewhat restless as a result of the medication, and one-fourth of them were extremely restless until quieted by small amounts of an inhalation anesthetic given before and during delivery. In the whole series,

there was no apparent slowing of labor except in one case, and in several cases labor seemed to be hastened. Changes in maternal blood pressure, pulse and respiration were those of normal labor. Third stage and postpartum complications were not increased. Fetal heart rates were not abnormally altered, but one-third of the babies were more or less apneic and required stimulation to establish respiration. Postnatal infant behavior and weight curves were not altered from the normal.

CONCLUSIONS

1. When the dosage and intervals are individualized, the intravenous administration of sodium amytal during the latter half of the first stage and during the second stage of normal labor induces satisfactory amnesia in nine out of ten cases.
2. Labor is rarely, if ever, prolonged by its use and may sometimes be hastened.
3. There is no evidence of harm to the mothers.
4. Slight to extreme restlessness results from its administration in one-half of the patients and is an objectionable feature of the procedure.
5. Restlessness can be controlled toward the end of the second stage and delivery facilitated by the use of an inhalation anesthetic, of which lesser amounts than usual need be administered.
6. One-third of the babies are somewhat apneic at birth, apparently due to a torpidity of the respiratory center induced by the drug, and require stimulation to establish respiration.
7. No other deleterious effects of the drug are observed in the postnatal behavior or weight changes of the babies.

MORE MISBRANDED NOSTRUMS

The following products have been the subject of prosccution by the Food, Drug and Insecticide Administration of the United States Department of Agriculture which enforces the Federal Food and Drugs Act: Palatol (Parke, Davis and Company of New York City), consisting essentially of cod liver oil, malt, wild cherry, phosphates, cholesterol, alcohol, sugar and water. Halanum (The Radium Research Foundation), containing no radium and being in fact essentially a weak solution of common salt in water. Eleven Bros. Tonic (Eleven Bros. Laboratories, Inc.), consisting essentially of epsom salt, iron chloride, alcohol and water, flavored with peppermint. Phenyo-Caffein (The Phenyo-Caffein Company), consisting essentially of acetanilide, caffeine and camphor. Fenholloway Sulphur Springs Water (A. E. Jackson), containing a filthy animal and vegetable substance. Bel-Caps (W. E. Shuit), containing ammonium, iron and calcium compounds, sulphates, carbonates, chlorides, bromides, camphor, aloin, small amounts of alkaloids and plant extractives, including a laxative drug. EfeDron Hart Nasal Jelly (The Hart Drug Corporation), consisting essentially of a mucilaginous mass containing ephedrine hydrochloride, chloretone, carbolic acid, salt and water flavored with oil of cinnamon. Crane's Laxative Quinine Cold Tablets (The Crane Medicine Company), each tablet containing 8/10 grain of acetanilide with quinine and cinchonine salts and a laxative plant drug. Bromoline (The Senoret Chemical Company) consisting of coated tablets containing acetanilide, cinchonine sulphate and resinous plant material. Grip-Sules (Kingsbury and Frick), capsules containing about 1½ grains of acetanilide, about ⅓ grain of caffeine, a quinine compound and a pungent drug, such as red pepper. Numoss (The C. R. Products Company), consisting of ammonium chloride, creosote and Irish moss, flavored with oil of anise. Hogan's Old Reliable Cough Syrup (Hogan's Old Reliable Cough Drops, Inc.), consisting essentially of ammonium chloride, red pepper, chloroform, extracts of plant drugs, including licorice, squill, wild cherry and senega, with alcohol, sugar and water, and flavored with oil of anise. (Jour. A. M. A., September 27, 1930, p. 951.)

THE USE OF SODIUM AMYLETHYL BARBITURATE IN NERVOUS DISORDERS*

L. R. Gowan, M.D.
Duluth, Minnesota

IN the treatment of the various types of psychoneuroses, and also in the more profound psychotic conditions, aside from the need of a thorough understanding of the individual personality make-up, a careful analysis of the existing conflicting emotional elements, and a study of his social conditions, there is, in many instances, a real need for medicinal therapy. The relief of daytime tensional states, such as extreme degrees of depression, excitability or anxiety, the alleviation of various painful stimuli, and the production of a sufficient amount of restful relaxation and sleep at night, without too great a depressive action the next morning, all contribute a real share toward relieving the psychoneurotic or psychotic case by preventing the exhaustion which accompanies emotional tension, inhibiting the reception of painful psychic stimuli, and improving the general physical tone of the body through obtaining a proper amount of rest.

In prescribing drugs for the relief of nervousness, the alleviation of pain or the production of sleep, there is great need for the careful study of the effect of the drug, its adaptability to the purpose for which it is intended, and a most careful individualization of dosage. That a given drug may affect different individuals in various manners and degrees is probably more true with psychiatric patients as a whole than with any other type of patients with whom we may come in contact. The literature sent out by various pharmaceutical and chemical houses which are producing an almost innumerable number of products, unfortunately labelled a trade name rather than the proper pharmacological term, must not be taken for granted. If we are to use these products, we must study them carefully, and determine for ourselves by actual clinical experience when they may be of benefit to a patient, the proper dosage in each instance, and the recognition of cases where their use is contraindicated. To illustrate the variability of action and the possible misuse of these drugs, let us consider three of the most commonly used products, namely, luminal, veronal and the various bromide salts. I have frequently encountered patients who have been prescribed luminal a grain and a half three times a day, whose condition required certainly not more than a half grain three times a day. On the smaller dose they made much more rapid improvement and were able to cooperate much better with the other phases of treatment. I have seen patients who have been prescribed veronal as a sedative during the day and luminal to produce sleep. Other cases have been prescribed allonal as a daytime sedative and bromides as an hypnotic. To me, these are examples of poorly adapted medication. In my experience, I have found luminal to be a much better sedative than a soporific, though if given in large enough doses, it will produce sleep, but will also be more depressing the next morning than many other drugs that might have been given in a smaller dose. I have found veronal too depressing to be used as a daytime sedative, yet a fairly efficient soporific, but requiring careful adjustment of dosage in order to avoid severe depressing reaction the following morning. I have found allonal a good analgesic, a poor sedative and a rather undependable hypnotic unless given in a dosage that almost certainly produces a depressed feeling upon awakening. I consider bromide salts useful as sedatives, of no value as analgesics and unsatisfactory as hypnotics unless given in large doses. I do not use bromides except over very short periods, on account of the tendency to produce gastric irritation and skin eruption.

Practically all these drugs, unless properly prescribed, have the possibility of harmful results. The literature contains numerous references to the production of a toxic rash from the use of luminal. Some cases will develop a rash from a very small dose, others only on

*Presented at the annual meeting of the Minnesota State Medical Association, Duluth, July 16, 1930.

large doses or prolonged usage. I have personally known a case that presented a rather typical picture of lethargic encephalitis, and was so diagnosed by three different physicians, that proved to be chronic luminal poisoning and cleared up on withdrawal of the drug. Veronal, if taken in large doses over a sufficient length of time, is extremely depressing, is altogether too readily obtained at drug stores, and frequently used by nervous psychotic individuals to permanently escape from their worldly cares and troubles. Toxic psychoses produced by overly large doses of bromides are not at all uncommon, and often deprive the individual of usefulness and adaptability to everyday life for a period of many months. I have in mind a patient who entered the hospital for an operation for a chronic ailment, who was very nervous in anticipation of the operation. By way of preparation, to settle her nerves, she was given sixty grains of bromides for four doses at quite frequent intervals over a two-day period. At the end of this time she was greatly excited, hallucinated and delusional. It was almost four months before she returned to her normal state.

From the foregoing, it would seem apparent that there is an opportunity for improvement on our present medicinal therapy of nervous states. There is a need for further judicious experimentation and careful clinical observation. The realization of this led me to investigate the possible adaptation of sodium amylethyl barbiturate. The successful use of this drug in the field of surgery in producing narcosis sufficiently deep to allow major surgical operations to be performed without any serious after-effects, indicated that it might well be a most useful agent in the field of psychiatry. A search of the literature has failed to reveal the experience of others who may have been using the drug with the same objective, although there are several articles dealing with its use in surgery.

This drug is the sodium salt of iso-amylethyl barbituric acid. It has been used rather extensively for several years as a general anesthetic in experimental pharmacological and physiological work. More recently, it has been prepared so that when protected against moisture and carbon dioxide, a stable compound, suitable for intravenous use, is obtained. It may be used intravenously, intramuscularly, orally or rectally. When prepared for intravenous use, it should be a five or ten per cent weight volume solution. The solution is affected by exposure to air, therefore it should be used within a short time after preparation, especially if given intravenously. If the solution is not perfectly clear after a four or five minute standing, it should not be used. The dose when used intravenously for controlling convulsive states such as are found in epilepsy, alcohol poisoning, meningitis and other convulsive states of a like nature, is from four to twelve grains. If repeated at frequent intervals, subsequent doses should be smaller, as it has been found to have a certain cumulative action, especially if given intravenously. However, this has not been my experience when the drug is given orally. When it is administered intravenously, close observation to determine the first signs of loss of consciousness affords valuable information regarding the additional amount which will be required to obtain the desired effect. Most patients who lose consciousness after the administration of three or four grains do not require as much additional amount of the drug as those who require five to seven grains before losing consciousness. Shortly after starting the injection of the drug, the patient gets drowsy and soon falls into a very deep sleep. Respirations are decreased in amplitude and there is a slight degree of cyanosis sometimes present. Respiration may become very difficult, cyanosis extreme, blood pressure fall dangerously low and the pulse become thready if the injection is given too rapidly or in too large a dose. The injection should not be more rapid than one cubic centimeter per minute. I have not personally experienced this reaction in any of my patients, due to giving the drug too rapidly. However, in one of my cases, a hospital interne administered the drug and the patient's respiration, blood pressure and pulse rate became alarming, though he rapidly regained a normal state following a short period of artificial respiration and cardiac stimulation.

This drug should not be given intravenously nor in large doses, otherwise, in cases suffering from generalized arteriosclerosis, hypertension or any pulmonary disease. It should also be given cautiously following large doses

of morphine or to patients who are sensitive to morphine and drugs of a similar nature. Patients who are known to be hypersensitive to other barbituric acid derivatives should not be given this drug. It has been my observation that its intravenous administration in the group of cases with which we are dealing, is indicated only in convulsive states and in cases where the patient's coöperation is not sufficient to allow the administration of the drug orally.

In the oral administration of the drug, it is best given in capsule form, as it has a bitter taste and is not well taken in powder form. In most cases where oral administration is possible, from six to twelve grains of the drug are usually sufficient to obtain sleep over a period of from five to ten hours. This is a smaller dose range than has been recommended for oral administration in surgical use. However, in the non-surgical case, the desired narcosis need not be so deep, therefore the dosage may be smaller. There is another point of difference between the non-surgical patient and the surgical patient. It has been observed that where this drug is given, followed by other anesthesia and operation, there is a considerable period of excitement upon the patient's awakening, followed by a further period of lethargy. This has not been my experience in giving it to non-surgical patients. This would indicate that the period of excitement and prolonged lethargic condition was not due to the drug itself, but due to a combination of factors such as the addition of other anesthetic agencies, surgical shock or other physiological reaction. Where oral or intravenous administration is not possible, the drug may be administered intramuscularly or rectally. I have had no experience with rectal administration of this drug. However, I have obtained very satisfactory results with intramuscular injections. When given intramuscularly, only a small amount, three or four cubic centimeters, should be injected at any one point, otherwise the point of injection will be quite painful and unnecessary tissue reaction result. When injected intramuscularly in small amounts, after a period of two or three days, there is no evidence of any tissue reaction nor is the area painful.

I have used this drug in the various types of cases that one encounters in the usual psychiatric practice. I have used it, to a large extent, for its sleep producing action. However, I have attempted to determine whether or not, in smaller doses, it might be valuable as a sedative. It is a most excellent drug in controlling convulsions when given intravenously. I have also used it in four cases of idiopathic epilepsy. These cases have been observed over a period of from three to four months. The average dose has been one and one-half to three grains two or three times a day. These cases were all previously on luminal therapy. In two cases there was no perceptible change in the frequency or severity of the convulsions. In one case the convulsions were more severe and more frequent than when on luminal therapy, and in one case the patient reported longer intervals between convulsions and some improvement in his general feeling of well-being. However, these cases have not been observed over a sufficient length of time to draw definite conclusions as to its value in epilepsy. As a daytime sedative in psychoneurotic cases, it has been my observation that the drug, unless given in very small doses, has too great a soporific action, and if given in small doses its action is very transient.

As a soporific in psychoneurotic cases, and also in psychotic cases attended by marked excitement and depression with severe insomnia, when given in carefully adjusted doses, it is a real aid in obtaining sufficient restful sleep with a minimum degree of depressant action.

THE PROBLEM OF DISEASE OF THE PARANASAL SINUSES*

HAROLD I. LILLIE, M.D.
Rochester, Minnesota

DISEASE of the sinuses is as old as man and has been dealt with continuously throughout the ages, as examination of skulls of ancient civilizations reveals. The generally prevalent pessimistic idea at this time that disease of the sinuses is not amenable to well directed treatment is not based on facts but usually has been spread by word of mouth. It is, I believe, true that we are now emerging from an era in which an overenthusiastic profession chose to assign disease of the sinuses to many symptoms referable to the head in particular, and to the body in general. For this reason, perhaps, many destructive intranasal and extranasal operations were performed without affording relief of symptoms, but more often resulting in adding new symptoms to the old. If operation was not performed, the patient would be occupied by home-treatment measures, and thus had many reasons to be introspective and pessimistic. Fortunately, the physiologic and pathologic causes of symptoms are better understood now and a much more rational, scientific and conservative era is in sight.

For better orientation, it might be useful to recall that the paranasal sinuses are a part of the upper respiratory tract, and, although their function is not well defined, they still are present and occasionally become diseased. The tract has a definite function in respiration performed by virtue of the highly specialized nearly automatically controlled mucous membrane. The function involves warming, moistening, and cleaning the air breathed. It is obvious that under certain environmental or climatic conditions the response would be variable. The environmental reaction will not be considered here. The maxillary, frontal, and sphenoid sinuses develop after birth and in certain instances, for unexplained reasons, do not develop symmetrically in pairs. The ethmoid sinuses are usually present at birth.

All sinuses communicate with the nose by small openings in the lateral wall underneath the middle turbinate except the posterior ethmoid and sphenoid sinuses, which empty into the postnasal space. The lining membrane is continuous with and similar to that of the interior of the nose except that it is thinner, and it has fewer glands and fewer blood spaces. It is easy to explain, then, why the sinuses may be involved in infections of the upper respiratory tract. Perhaps, if the nose and appendages were more often spoken of as the upper respiratory tract, their function, and the physiologic and pathologic phenomena relating to them would be better understood. Infections of the upper respiratory tract are so frequently encountered and usually so self-limiting that they are not often given serious consideration, although from an economic standpoint such infections are significant. Infections of the lower respiratory tract have always received serious consideration.

The direct etiologic factor in disease of the sinuses, as has been intimated, is the severe infection of the upper respiratory tract. The sinuses become involved by contiguity and continuity, and because of the inadequate size of the opening into the nose, resolution is protracted or does not occur until well directed interference is instituted. The maxillary sinus may become involved by contiguity to an infected tooth. The occurrence of such involvement has been variously estimated as between 12 and 25 per cent.

The use of various aqueous solutions in nasal irrigations and sprays has a time-honored precedent, but as early as 1844 it was pointed out that for physiologic and pathologic reasons, they were not without great danger. Such solutions denude the surface of the membrane of its greatest protective mechanism, and produce pathologic changes. The only excuse for their use is that irrigations have offered a convenient method of clearing the nasal passages.

The habit of blowing the nose may have much to do with causing infections of the sinuses by forcing infected material into the sinuses. Animals have infection of the sinuses as the result of infections of the upper respiratory tract but not as a result of blowing the nose.

Underlying the immediate etiologic factor, however, is the large general problem of hygiene, allergy, dietetics and preventive medicine. Each

*From the Section on Otolaryngology and Rhinology, The Mayo Clinic, Rochester, Minnesota. Read before the Minnesota State Medical Association, Duluth, July 14 to 16, 1930.

might well be the subject of discussion. I would suggest, however, that the frequency of "head colds" is not nearly so dependent on the particular anatomic arrangement or condition of the structures encountered in the upper respiratory tract, as is hygiene, including environment, mode of living, occupation, manner of dress and diet. It has been shown experimentally that animals may be made less resistant to infections of the upper respiratory tract by certain diets, and that by change of diet all symptoms can be made to disappear. It is seen, then, that the problem of disease of the sinuses is not entirely that of the rhinologist but begins with the guidance of the general profession.

The severity of the symptoms in acute sinusitis, so far as pain and discomfort are concerned, is due to the intense congestion of the membranes. Not until this congestion is relieved by the natural process of secretion will relief be afforded. To hasten the onset of secretion is the aim of treatment at this stage. The most effective means has been found to be general measures, such as rest in bed in semi-upright position, steam inhalations, hot moist packs over the face, saline catharsis, and coal-tar products by mouth. The severe symptoms usually last over a period of forty-eight hours, or the time usually necessary for the secretory mechanism to function properly. After this period shrinkage of the nasal membranes induced by topical applications of astringents followed by gentle suction will markedly relieve the symptoms, and will hasten resolution. Surgical measures at this stage are dangerous, for an avenue for extension of infection toward the meninges is opened. Most patients with acute sinus trouble will go on to an uneventful convalescence under this regimen.

If certain symptoms, such as localized pain, occurring usually in the morning hours and subsiding at midday, and copious purulent secretion continues to be troublesome after a period of a week or ten days, depending on the severity of these symptoms, one may decide to continue local treatment or to use certain conservative surgical measures. In case such treatment does not favorably affect the disease, it becomes chronic, and cases may be grouped as follows: (1) serous or, as commonly called, catarrhal, (2) purulent, (3) hyperplastic, or polypoid, and (4) a combination of these. The problem, then, rightly belongs to the rhinologist.

It may be said that the signs and symptoms of disease of the sinuses are usually quite definite and that there is little difficulty in making a diagnosis. Roentgen examination has become increasingly important as an adjunct diagnostic aid in disease of the sinuses. Whoever interprets the picture must be conversant with the anatomy, the anatomic variations and pathologic changes of the paranasal sinuses. The roentgenogram can be very misleading. Roentgenograms are usually more accurate in the diagnosis of conditions other than suppuration, such as tumors, foreign bodies, osteomas, and changes in bone. When roentgenograms are used in conjunction with other diagnostic aids, however, their aid is invaluable.

Again the diagnosis of disease of the sinuses may be quite difficult and the accurate site of the sinus or sinuses involved may require repeated eliminative examinations in the course of several days of observation. For instance, it might seem easy to say, in conjunction with definite physical changes in the middle meatus, that the ethmoid sinus is involved. When one remembers that the maxillary and frontal sinuses empty into the middle meatus and the presence of this pathologic secretion may cause visible physical changes of the membranes without involvement of the ethmoid sinus itself, it becomes necessary to decide definitely whether or not the ethmoid sinuses are involved. Many times, in my experience, counter-draining the maxillary sinus into the inferior meatus has caused the appearance of the middle meatus to change completely, and operation on the ethmoid sinus was thus avoided. It is difficult to understand how isolated ethmoid cells could become involved without signs, except in cases in which they are infected from an infected lacrimal sac. Patients frequently present themselves with the complaint that they have disease of the sinuses, either self-diagnosed or because of some symptom an acquaintance may have suggested was due to disease of the sinuses.

In general, it may be said that well directed intranasal operations will clear up disease of the sinuses in most cases, if serious pathologic changes have not occurred in the mucous membrane and bone. The principle of treatment involved is drainage and ventilation.

When profound pathologic changes have taken place in the mucous membrane and bone,

the radical external operations must be employed. In this instance, the principle of treatment involved is the removal of the disease.

In the past, the radical operations of the frontal sinus resulted in seriously deforming scars but at present this often can be avoided. From my own standpoint, the hyperplastic disease of the ethmoid is the most difficult to deal with satisfactorily.

The results in general are satisfactory. It must be admitted, however, that it is not always possible to effect a restitutio ad integrum status of the parts. This fact, perhaps, explains why certain patients have post-operative symptoms not due to disease but to altered physiologic reactions.

It should be pointed out that pain and headache caused by other intranasal disorders than disease of the sinuses, or eye strain, migraine, neuritis of the nasal ganglion, brain tumors, constipation, toxemia, and so forth, are not benefited by operations of the sinuses no matter how well performed. Vasomotor rhinitis, usually the manifestation of some general disturbance, or allergy, endocrine, or other causes, has been frequently treated as sinusitis, with obviously unsatisfactory results. Symptoms referable to the reaction of the mucous membrane to its environment, such as stuffiness under certain climatic conditions, dropping of mucus into the pharynx, or coughing, are not explained on a basis of disease of the sinuses.

The relation of disease of the sinuses to the focal infection theory of causation of disease is important. I believe that the sinuses too often have been considered important foci, even when there were no manifest signs of sinusitis. There has been a radical change of opinion within the last five years in regard to posterior ethmoid and sphenoid sinuses as the causative factor in retrobulbar neuritis. However, the sinuses may be the definite cause of focal infection. We all have had such cases. A recent review of 400 consecutive cases of frank chronic suppurative sinusitis gave a surprisingly low incidence of syndromes of focal infection. It seems obvious that frank sinusitis when present should be taken care of although it may not be the focus causing the trouble. If treatment for such conditions is to be rational and well directed, all foci of infection must be investigated.

SUMMARY

There is nothing mysterious or mystical about disease of the paranasal sinuses. The results of well directed treatment are satisfactory. There is no reason why the general prevalent idea that "once a sinus disease, always a sinus disease" should obtain. A better understanding of the function, physiology and treatment of the paranasal sinuses will overcome this attitude.

SYNTHETIC THYROXINE

The A. M. A. Chemical Laboratory recalls that Kendall isolated thyroxine from the thyroid gland and that he considered it to have a constitution which later was found to require revision and that in the U. S. Pharmacopeia thyroxine is defined as an active principle obtained from the thyroid gland. Attention is called to the fact that while spelled in the Pharmacopeia without a final "e" the substance is basic in character and must be spelled thyroxine. Three years ago, Harington and his co-workers arrived at the conclusion that the Kendall formula was not correct. Later this conclusion was confirmed by the preparation of thyroxine synthetically. Synthetic thyroxine has been prepared by pharmaceutic laboratories abroad and one brand, Synthetic Thyroxine-Roche, has been submitted to the Council on Pharmacy and Chemistry. The Laboratory found this brand to comply with the standards which it had elaborated and the Council admitted this product to New and Non-official Remedies for the reason that the pharmacopeial definition does not apply to the synthetic substance. (Jour. A. M. A., August 16, 1930, p. 484.)

PALSY OF THE CRANIAL NERVES*

Lloyd H. Ziegler, M.D.
Rochester, Minnesota

In an endeavor to evaluate the significance of palsy of the cranial nerves, a study was made of the record of 213 cases that were selected at random. In these cases, partial or complete palsy of the cranial nerves was referable to 474 cranial nerves. These are classified in tables 1 and 2. The problem naturally divided itself into the recognition of various degrees and types of such palsy, and as accurate an interpretation of them as possible. The clinical diagnoses were proved by necropsy in four cases only. Strong corroborative evidence was furnished by biopsy in twenty-five cases and by operation in thirteen cases. Clinical tests (chiefly serologic and roentgenographic) were supportive in eighteen cases. In all others, the pathologic and etiologic agents were suspected from evidence varying from an epithelioma plainly in view to the association of palsy with trauma or infection. That such evidence can be misinterpreted is exemplified by observations at necropsy in one case in which there had been palsy of a series of cranial nerves. This was thought to be due to extension of a tumor. It was found that the neoplasm had eroded a small hole through the skull, permitting infection to enter and cause the localized meningitis which was responsible for the palsy of the cranial nerves.

With the foregoing plan, each cranial nerve will be considered in a way suggestive of the natural clinical approach to problems of the nerve. Only the most fundamental facts concerning lesions of cranial nerves can be presented.

FIRST OR OLFACTORY NERVE

The first nerve consists of many fine nerve fibers entering the upper pole of the nasal cavity through the cribriform plate subserving the function of smell. From a partial lesion of the nerve the patient might not notice anything. From a complete lesion of this nerve the patient might or might not be aware of the absence of smell (anosmia). To elicit a complete lesion of this nerve the examiner uses volatile substances such as camphor, benzine and oil of wintergreen, and tests one nostril while the other is closed. The complete inability to smell these substances is far more significant than the failure properly to recognize them. If the sense of smell seems to be absent, the following possibilities must be eliminated before cranial nerve palsy can be considered: (1) nasal obstruction; (2) scars in the nose from disease or operation; (3) the presence of ozena, and (4) congenital absence of smell.

Conditions that may cause palsy of the cranial nerves are (1) brain tumor involving the basifrontal region; (2) endothelioma of the olfactory groove; (3) fracture of the base of the skull, and (4) meningitis.

SECOND OR OPTIC NERVE

The second nerve, the largest cranial nerve, enters the orbital cavity through the optic foramen and by means of the eye subserves the functions of vision for color and form. From a partial lesion of this nerve the patient might or might not be especially aware of defective vision although a very slight lesion of the maculopapillary bundle would express itself as defective visual acuity (amblyopia). A complete lesion of the nerve produces blindness (amaurosis). To elicit a partial lesion the ability to see very small colored objects at a given distance, to read various standardized print, to count fingers, to see moving objects, or to perceive light are tests which are employed. Various grades and types of defect of vision were presented by Lillie. In the case of amblyopia, or defect of vision, the following possibilities, among others, must be eliminated before a lesion of the optic nerve can be established: (1) refractive errors; (2) opacity of media of eye; (3) disease or destruction of macula, retina, or choroid; (4) glaucoma; (5) defect of intelligence; (6) disease of optic pathways back of optic chiasm; (7) congenital defect, such as color blindness; (8) defect of muscles necessary for binocular vision, and (9) hysteria.

Conditions that may cause palsy of the optic nerves are: (1) multiple sclerosis, in which the

*From the Section on Neurology, The Mayo Clinic, Rochester, Minnesota. Read before the Minnesota State Medical Association, Duluth, July 14 to 16, 1930.

optic nerves are often affected; (2) retrobulbar neuritis, which sometimes proves later to be multiple sclerosis; (3) tumor of the basifrontal region, causing injury to the optic nerves; (4) pituitary tumor; (5) basilar meningitis (syphilitic, tuberculous or meningococcic); (6) secondary optic atrophy from choked disks from intracranial pressure, and (7) primary optic atrophy.

* Evidence supporting the diagnosis afforded by necropsy in four cases, biopsy in twenty-five, operation in thirteen and clinical tests (chiefly serologic and roentgenographic) in eighteen.
** These may or may not be due to lesion of the nerve.

THIRD OR OCULOMOTOR NERVE

The third nerve enters the orbital cavity through the superior orbital fissure and supplies the muscles to elevate the lids and to move the eyes upward, downward and toward the nose. The inferior oblique muscle moving the eye upward and outward is also supplied by it. In addition the pupillary constrictor and ciliary muscle for accommodation are supplied by fibers associated with it. Partial lesion would be likely to cause diplopia with the patient looking in various directions, and might cause ptosis of the eyelid and fixation of the pupil. With complete lesion the patient would notice complete ptosis, diplopia in looking up, down or to the nasal side, fixation of the pupils to light, and difficulty in reading without corrective glasses, due to failure to accommodate. The types of diplopia due to complete paralysis of the third nerve were presented by Fuchs.[1] The examiners would notice in the case of a complete lesion on elevating the ptosed lid the inability to rotate the eye upward, downward or nasalward, and fixation of the pupil to light and accommodation (Fig. 1). In cases of apparent partial or complete paralysis of

the third nerve the following conditions must be eliminated: (1) congenital ptosis (usually bilateral); (2) the apparent ptosis due to Horner's syndrome, the result of paralysis of the cervical sympathetic nerves; (3) disorders of the muscle of the eye (muscular dystrophy and atrophy) which simulate palsy of the cranial nerves; (4) asymmetric positions of the eyes; (5) disease of the nucleus of the nerve and (6) disease of the midbrain producing weakness of conjugate movements of the eye.

Palsy referable to the third cranial nerve seems to be most commonly caused by inflammation or injury at the base of the brain, such as that due to syphilis or to tuberculosis.

THE FOURTH OR TROCHLEAR NERVE

The fourth nerve enters the cranial cavity through the superior orbital fissure and supplies the superior oblique muscle which rotates the eye downward and inward. Partial paralysis of this nerve may produce diplopia. Complete paralysis would do little more. Patients with this lesion sometimes tilt their heads to compensate for the oblique diplopia. Paralysis of this nerve is not detectable by the examiner without special meth-

Table 3

CONDITIONS THAT MAY BE CONFUSED WITH PALSY OF THE CRANIAL NERVES

First Nerve	Fourth Nerve	Eighth Nerve
Nasal obstruction	Lesions of the other ocular motor nerves	Obstructive deafness
Operative scars in nose		Mental deficiency
Ozena	**Fifth Nerve**	Schilder's disease
Congenital absence of smell	Paresthesia as seen in psychosis	Disease of the midbrain
Second Nerve	Syringobulbia	Pineal tumor
Refractive errors	Lesions of the brain stem	**Ninth and Tenth Nerves**
Opacity of media of eye	Lesions of the upper cervical portion of the cord	Hoarseness from laryngitis
Disease of macula, retina or choroid	**Sixth Nerve**	Difficulty in swallowing from nasal or esophageal obstruction
Glaucoma	Defects of muscle	Medullar lesions
Mental deficiency	Ocular asymmetry	**Eleventh Nerve**
Disease of optic pathways	Disease of the brain stem	Arthritis of neck and shoulder
Congenital defects, color blindness and so forth	**Seventh Nerve**	Monoplegia
Defect of muscles necessary for binocular vision	Nuclear lesion	**Twelfth Nerve**
Hysteria	Lesion of cortical motor area	Nuclear lesion, as in bulbar palsy
Third Nerve	Asymmetry of the face	Pseudobulbar palsy
Congenital ptosis	Hemiatrophy of the face	Sore tongue
Horner's syndrome	Hemihypertrophy of the face	
Muscular dystrophy and atrophy	Edema of one side of the face	
Ocular asymmetry	Contracture of one side of the face	
Disease of the nucleus of the nerve	Muscular disorders of the face	
Disease of the midbrain		

Table 4

CONDITIONS THAT MAY CAUSE PALSY OF THE CRANIAL NERVES

First Nerve	Fourth Nerve	Eighth Nerve
Basifrontal tumor	Inflammation or injury of the base of the brain	Tumor of the cerebellopontine angle
Endothelioma of olfactory groove	**Fifth Nerve**	Basilar meningitis
Fracture of the base of skull	Tumor of the cerebellopontine angle	Disease of the inner ear
Residual of meningitis	Tumor of the gasserian ganglion	Familial degeneration
Second Nerve	Tumor of the nasopharynx	Fracture of base of skull
Multiple sclerosis	**Sixth Nerve**	Toxic neuritis (mumps, tobacco, alcohol)
Retrobulbar neuritis	Intracranial pressure	**Ninth and Tenth Nerves**
Basifrontal tumor	Otitis media	Retroparotid tumor
Basilar meningitis	Lesions at the base of skull	Injury, as in thyroidectomy
Secondary optic atrophy	**Seventh Nerve**	**Eleventh Nerve**
Primary optic atrophy	Inflammation (Bell's palsy)	Injury
Third Nerve	Tumors or inflammation at the base of the brain	Retroparotid tumor
Inflammation or injury of the base of the brain	Fracture of the base of the skull	Inflammation
	Peripheral neuritis	**Twelfth Nerve**
		Retroparotid tumor

ods such as the colored glasses for differentiating images, and even then with some difficulty.

Lesions of this nerve, especially isolated ones, are not common and their detection is rare. The nerve is subject to the same disease processes as

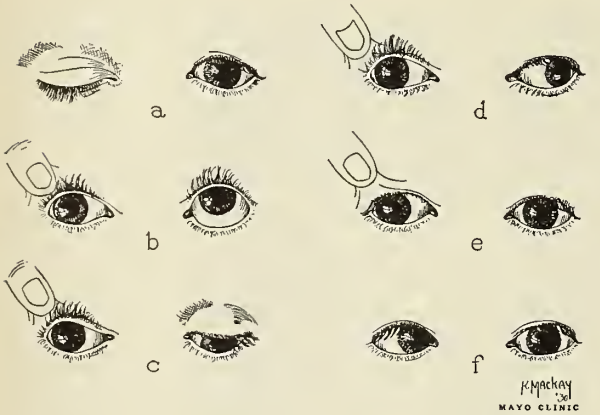

Fig. 1. *a* to *e*, Manifestations of complete palsy of the right third cranial nerve: *a*, ptosis; *b*, position of the eyes on looking upward; *c*, position of the eyes on looking downward; *d*, position of eyes on looking to the left; *e*, position of eyes on looking straight forward; *f*, appearance of the eyes in complete palsy of the right sixth cranial nerve on looking straight forward.

the third nerve, with which it is closely associated.

FIFTH OR TRIGEMINAL NERVE

The fifth nerve, the largest except the optic and composed of three divisions, sends the branches of the first division, or ophthalmic nerve, into the orbital cavity through the superior orbital fissure; the second division, or maxillary nerve, leaves the skull through the foramen rotundum, and the third division, or mandibular nerve, leaves the skull through the foramen ovale. The nerve supplies fibers carrying pain, temperature and tactile sensibility to the face and fore part of the scalp as well as to the mucous membrane of much of the oral and nasal cavities and tongue. It also has a motor root supplying the muscles of mastication. From a partial lesion of the nerve a patient might notice numbness of the face on the side of the lesion. A complete lesion would cause the patient to notice complete anesthesia of the face and there might be some trouble in chewing food on the side of the lesion. If the lesion has existed for a considerable time, there may be trophic disturbances of the eye, wrinkling of the cornea or corneal ulcers on the side of the lesion. In case of complete lesion, the examiner would notice a defect of the masseter, and possibly of the temporal muscle and the lower jaw would deviate to the paralyzed side because of paralysis of the pterygoid muscle (Fig. 2). The patient would not feel pin pricks, cotton wool, or heat and cold

Fig. 2. Manifestations of palsy of the motor branch of the fifth nerve; *a*, right pterygoid palsy, jaw deviating to the side of the lesion; *b*, atrophy of the left masseter.

stimulation over the side of the face. The cornea would be so insensitive that it could be touched with cotton or a pin head without the patient's awareness. In cases of apparent lesions of the fifth nerve the following possibilities must be eliminated: (1) paresthesia of the face such as is seen in certain cases of psychosis; (2) syringobulbia (cavity in the brain stem); (3) other lesions of the brain stem, and (4) lesions of the upper cervical portion of the spinal cord.

Lesions (usually partial) of the fifth nerve that may cause palsy are: (1) tumor of the cerebellopontine angle, which is one of the most common causes, (2) complete lesion of the fifth nerve in cases of tumor of the gasserian ganglion, and (3) tumor of the nasopharynx.

SIXTH OR ABDUCENS NERVE

The sixth nerve enters the orbital cavity through the superior orbital fissure. It is a motor nerve to the external rectus muscle of the eye. From a partial lesion of the nerve the patient might notice diplopia in looking in some directions. From a complete lesion the patient would have diplopia. In case of complete lesion the examiner would notice internal strabismus on the side of the lesion, and to demonstrate the defect the patient should be asked to look to the extreme side of the lesion, in which case the eye would not move toward the external canthus. If the sixth nerve seems to be paralyzed, the following conditions must be eliminated: (1) de-

fects of muscle, (2) asymmetry of the eyes, and (3) disease of the brain stem.

Palsy referable to the sixth nerve may be caused by (1) intracranial pressure, (2) sometimes by otitis media (Gradenigo's syndrome), and (3) sometimes by lesions at the base of the skull.

Fig. 3. *a*, Complete palsy of the left facial nerve; *b*, inability to wrinkle left side of forehead; *c*, inability to close left eye; *d*, inability to show teeth on left side; *e*, inability to whistle out of left side of mouth; *f*, inability to contract left platysma.

SEVENTH OR FACIAL NERVE

The seventh nerve leaves the skull through the stylomastoid foramen. It has a long circuitous course. It supplies the muscles of the face and ear and the taste fibers to the anterior two-thirds of the tongue. If it were partially paralyzed, the patient would notice inability to use the facial muscles naturally. In complete paralysis the patient would not be able to move the muscles of the paralyzed side, such as in wrinkling the forehead, closing the eye, whistling, showing the teeth, or drawing the corners of the mouth down (Fig. 3). If the lesion is complete, sometimes patients notice loss of taste on the side of the lesion. The effects of the lesion are most obvious to the examiner in asking the patient to perform these movements. Taste can be tested by placing sour, bitter, salty, or sweet objects on the anterior two-thirds of the tongue, and on the side of the lesion, and having the patient point to a chart with the names of the tastes on it. When there appears to be a lesion of the seventh nerve, the following conditions should be eliminated: (1) lesion of the nucleus of the nerve; (2) lesion of the facial region of the motor area of the brain (involves only lower part of face); (3) asymmetry of the face; (4) hematrophy of the face; (5) hemihypertrophy of the face; (6) edema of one side of the face; (7) contracture of one side of the face; (8) disorders of the muscles per se, such as muscular dystrophy and myasthenia gravis.

If palsy referable to the seventh nerve is present, the commonest causes are: (1) inflammation (Bell's palsy); (2) tumor or inflammation involving the base of the brain; (3) fracture of the base of the skull, and (4) sometimes in severe peripheral neuritis bilateral palsy of the seventh nerve which is sometimes difficult to recognize but is usually associated with other types of palsy of the cranial nerves.

EIGHTH OR VESTIBULO-ACOUSTIC NERVE

The eighth nerve subserves the functions of hearing and of equilibrium. From a partial lesion of the caustic portion of the nerve the patient may notice defect in hearing. Complete lesion produces absolute deafness. The examiner may, by rough tests, such as watch tick, elicit defects. Newer methods have recently been developed for more accurately measuring the defects of hearing. Partial or complete lesion of the vestibular portion may not be noticed by the patient, but while a lesion of this nerve is being produced, vertigo may be prominent. In cases of apparent palsy referable to the eighth nerve, the following conditions must be eliminated: (1) obstructive deafness; (2) defective intelligence; (3) Schilder's disease; (4) disease of the midbrain, and (5) pineal tumor.

Conditions that may cause palsy of the cranial nerves are: (1) tumor (unilateral) of the cerebellopontine angle; (2) basilar meningitis; (3) inflammatory disease of the inner ear; (4) familial degeneration of the eighth nerve; (5) fracture of the base of the skull, and (6) toxic neuritis of the eighth nerve, such as occurs during mumps and after excessive use of alcohol and tobacco.

NINTH OR GLOSSOPHARYNGEAL NERVE AND TENTH OR VAGUS NERVE

The ninth and tenth nerves leave the skull through the jugular foramen. It seems impossible at present completely to distinguish the function of one of these nerves from the other. The ninth nerve supplies the taste fibers to the posterior third of the tongue, motor fibers to the stylopharyngeal muscle, and probably sensory fibers to the pharynx. The tenth nerve probably supplies motor fibers to the constrictor muscles of the pharynx and soft palate. It supplies the motor fibers to the vocal cords, and afferent and efferent fibers to many of the thoracic and abdominal visceral structures. It is doubtful whether a patient would notice symptoms from a partial or complete isolated lesion of the ninth nerve. A lesion of the tenth nerve would result in hoarseness and inability to swallow properly.

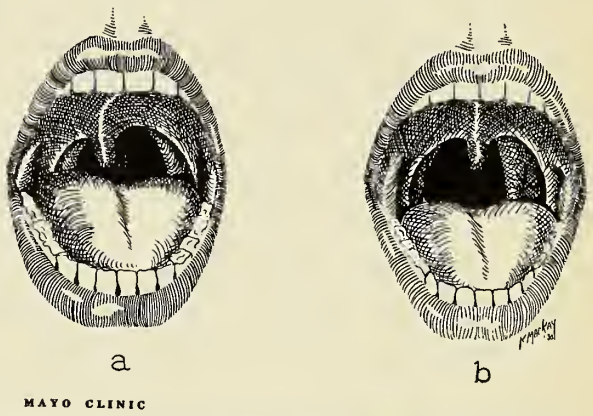

Fig. 4. Manifestations in palsy of the ninth and tenth cranial nerves: *a*, palsy of the left soft palate; *b*, palsy of the right constrictor of the pharynx.

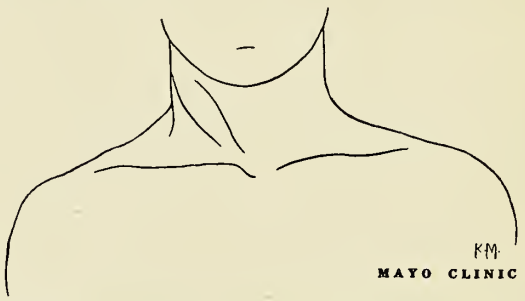

Fig. 5. Appearance of palsy of the left sternomastoid muscle. Manifestations of palsy of the eleventh cranial nerve.

The examiner could elicit weakness on one side of the soft palate by having the patient say "Ah," and of the pharyngeal muscles by putting a tongue depressor against the posterior pharyngeal wall to initiate a gag reflex (Fig. 4). In the presence of a complete lesion the laryngoscope reveals the vocal cord in the cadaveric position. If the lesions of the ninth or tenth nerve are suspected, the following conditions must be eliminated: (1) hoarseness due to laryngitis; (2) difficulty in swallowing due to an obstructive lesion of the esophagus or nasal obstruction, and (3) lesion of the medulla, such as that manifested by symptoms referable to occlusion of the posterior inferior cerebellar artery.

Conditions that may cause palsy of these cranial nerves are: (1) retroparotid tumor, or tu-

mor invading that region, and (2) injury, as in thyroidectomy.

ELEVENTH OR SPINAL ACCESSORY NERVE

The eleventh nerve makes its exit from the skull through the jugular foramen. It supplies

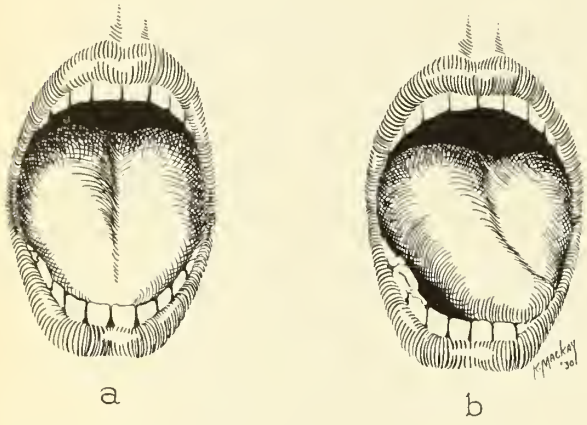

Fig. 6. Manifestation of palsy of the twelfth cranial nerve: *a*, normal tongue; *b*, palsy of the left twelfth cranial nerve, showing the tendency of the tongue to deviate to the side of the lesion.

the motor fibers to the upper portion of the trapezius and to the sternomastoid muscles. Partial or complete lesions would be known to the patient by inability to elevate the shoulders, as in shrugging (Stewart). The examiner would notice weakness and lack of prominence to the sternomastoid muscle by turning the patient's head away from the side of the lesion (Fig. 5). In cases of apparent lesion of the eleventh nerve, the following conditions should be eliminated: (1) arthritis of the shoulder or neck, and (2) monoplegia.

Palsy of this cranial nerve may be caused by (1) injury, not infrequently; (2) retroparotid tumors, and (3) inflammation.

TWELFTH OR HYPOGLOSSAL NERVE

The twelfth nerve makes its exit from the skull through the canalis hypoglossi. It is a motor nerve and supplies fibers to muscles of the tongue. If the nerve is partially paralyzed, the tongue is not so facile in its movement as normal, especially to the side opposite the lesion. If complete lesion is present, the tongue protrudes to the paralyzed side (Fig. 6). The patient notices difficulty in talking. The examiner may elicit weakness of the tongue by having the patient push the tongue into each cheek as far, and with as much force, as possible. Conditions that must be eliminated before palsy of the cranial nerves can be considered are: (1) nuclear lesions, as in bulbar palsy; (2) pseudobulbar palsy, and (3) sore tongue.

If a lesion of the twelfth nerve is present, retroparotid tumor is the most probable cause.

COMMENT

Complete paralysis of an isolated nerve (except the fourth) supplying the muscles of the eye produces a relatively simple and easily detected clinical picture. Partial or complete paralysis of more than one nerve may make the resulting clinical syndrome difficult to interpret.

There may be much pain in the distribution of a nerve such as the fifth or ninth, without demonstrable defect in the sensory or motor functions of these nerves.

During and following the epidemic of influenza in 1918, more patients were seen with partial palsy of the cranial nerves (especially of the third, fourth and sixth nerves) than had been seen previously. Many of these patients recovered but in some instances typical sequelæ of epidemic encephalitis developed.

Often the first symptom of nasopharyngeal tumor is pain in the region of the distribution of the fifth nerve and this nerve usually is involved early. Such tumors are probably responsible for more cases of palsy of the cranial nerves than any other cause; the palsy usually is confined to the side of the tumor. Retroparotid (mixed) tumors usually involve the ninth, tenth and eleventh nerves and sometimes the twelfth nerve, and produce the Jackson, or jugular foramen syndrome. Tumors of the acoustic portion of the eighth nerve almost invariably involve the fifth nerve on the side of the lesion.

Syphilis and tuberculosis involve especially the nerves to the optic muscles. Fractures through the base of the skull frequently involve the seventh and eighth nerves, although others may be affected as well.

Although it may not be easy to determine in the case of a motor nerve whether the muscle, nucleus of the nerve, or upper motor neurone is involved, the site of the lesion can often be determined. If the muscle is involved, the texture of the muscle as determined by palpation or biopsy may be of value. Also muscles in widely

separated regions may exhibit signs of disease. If the nucleus of the nerve is involved, muscular atrophy and fibrillary twitchings are usually seen in the muscles supplied by the nerve. In case a lesion of the upper motor neurone is suspected, the presence of signs elsewhere caused by the upper motor neurone, such as Hoffman's or Babinski's signs, may help to cast evidence in favor of such a conclusion. In the case of lesions of the sensory nerves, one must always rely on the subjective sensations and reactions of the patient. These are full of pitfalls, the avoidance of which, nevertheless, becomes an art of the experienced neurologist.

Thus if palsy of the cranial nerves seems to be present, its presence should be proved, if possible. After its presence is fairly well established the etiologic agent may be strongly suspected or even fairly well proved by the aid of information derived from careful history taking, by a careful examination of the whole body, and by the aid of well selected clinical tests. There is no place where careful day-by-day observation is so essential.

STUDY OF INFLUENZA MORTALITY IN SIX EPIDEMICS 1920-1929

The Public Health Service has recently completed a study of influenza mortality in six epidemics. This study is based on weekly death rates from respiratory diseases recorded as influenza and pneumonia in about 95 cities of the United States during the period 1920-1929.

From January 1, 1920, to the middle of 1929 six epidemics of more or less national extent have occurred in the United States—1920, 1922, 1923, 1926, spring of 1928, and the winter of 1928-29. Judging by the rates in the 95 cities, which seem to be only slightly higher than rates for the country as a whole, these six epidemics caused in excess of the normal or expected seasonal mortality from respiratory diseases recorded as influenza and pneumonia, approximately 250,000 deaths in the country as a whole—a total of nearly one-half as many deaths as occurred in the United States during the great pandemic of 1918-19. About one-fifth of these deaths, or 50,000, occurred during the recent epidemic of the winter of 1928-29, and two-fifths, or 100,000, occurred during the sharp epidemic of the early months of 1920.

Although these six epidemics were more or less nation-wide in extent, the various sections of the United States were by no means equally affected. In the instance of several of the smaller epidemics there appeared to be whole sections of the country that were not affected. On the other hand, certain sections of the country experienced fairly sharp epidemics in years when the rates for the country as a whole did not indicate any influenza-pneumonia deaths in excess of the median weekly rates. An example of this is an epidemic in the West South Central cities which occurred in the early months of 1925, a year when the remainder of the country appeared to be relatively free from influenza.

The point of origin and direction of progress of these six epidemics varies a great deal. Nearly every one of them arose in a different section of the country. The 1920 epidemic arose in the East North Central section and progressed very rapidly to all other sections of the country. The 1922 epidemic arose in the East, probably in the Middle Atlantic section, and the 1923 epidemic arose in the East South Central section. The 1926 and the 1928-29 epidemics arose on the West Coast, and the little epidemic of the spring of 1928 probably arose in the Mountain or West South Central section.

The rate of progress across the country varies a great deal in the different epidemics. Considering the 95 cities as a whole, however, there is more uniformity in the length of the epidemic. In 1920 the central half of the deaths occurred in a period of about 16 days. In the epidemics of 1928-29, 1922, and 1926 the central half of the deaths occurred in periods of 21, 22, and 23 days, respectively. In the small epidemic of the spring of 1928 the period was 27 days, and in the epidemic of 1923 the period was 30 days. The 1923 epidemic seems to show the least time-concentration of any of these recent outbreaks. In the case of all the other epidemics the excess rate rose and fell at about the same rate, but in 1923 the rise to the peak was considerably slower than the fall of the curve to the normal level again.

ENCEPHALITIS*

William H. Hengstler, M.D., and George N. Ruhberg, M.D.
Saint Paul

SINCE the onset of the first great epidemic in 1917, the most characteristic feature of epidemic encephalitis has been its protean manifestation and the widespread dissemination of its involvement of the nervous system. No mere enumeration of signs and symptoms, or the orderly grouping into clinical types, can give an adequate picture of the symptomatology of this disease. The lesions giving rise to the symptoms may be scattered from the frontal pole to the conus medullaris. For that reason the grouping into clinical types of this disease has been misleading. For a brief presentation the symptoms may be grouped into general and focal during the acute stage, and the general aspects of the chronic stage considered.

Fever is present as a rule during the acute stage, but is usually of only moderate intensity —99 to 101 degrees—and of short duration. In a large majority of cases headache, either moderate or severe, is usually present. Disturbance of the sleep mechanism is common. Lethargy was a very prominent feature of the early epidemic, but its prominence has markedly decreased in recent years. Insomnia in a severe and persistent form was quite common in later epidemics. Insomnia by night and drowsiness by day is often encountered. Delirium, excitement, clouding of consciousness and disorientation are the mental signs most often met in the acute stage.

In considering the focal symptoms it must be borne in mind that the portion of the central nervous system least spared is the mid-brain, brain stem and the basal ganglia. The symptoms, therefore, are in the main directly related to these regions. The cerebral cortex, pyramidal system, spinal cord, and spinal roots are occasionally affected, but infrequently in relation to the upper mid-brain and basal ganglia. Ocular disturbances are the most constant and important of the focal symptoms, and are present in the great majority of cases. The subjective complaints of these symptoms are blurring of vision and diplopia. Inequality and irregularity of the pupils are common; in addition the reaction of the pupils to light and in accommodation may be absent. Papilledema and, rarely, choked disc may be present. Ptosis, usually slight, and either unilateral or bilateral, is quite frequently found. External ophthalmoplegia caused by impairment usually of the third or sixth cranial nerves is another important focal symptom. Conjugate ocular convergence is frequently impaired. Facial weakness, either of the upper or lower motor neuron type, and usually slight and transitory, is often found. Vertigo is sometimes encountered. Choreiform movements, myoclonus, hiccough and tremor have often been met with in the acute stages of the past, but are not so common at present. The reflexes are variable. Occasional signs of meningeal irritation, of stiff neck and positive Kernig are found. The spinal fluid may be negative. Moderate increase of lymphocytes, increased pressure, a luetic gold curve, and normal or increased sugar content, on the other hand, are common spinal fluid findings.

There is no doubt but that the virulence of the disease has diminished until now the cases we encounter are not so severe in their manifestations. For this reason it is often difficult to make a correct diagnosis. In the recent cases we have found the most prominent symptoms to be headache, blurred vision, insomnia or drowsiness, moderate fever usually of short duration, and occasional rise in cell count in the spinal fluid. The onset is often insidious. The usual seasonal incidence occurring during the winter months has disappeared, until now cases are more or less sporadic.

It is now recognized that epidemic encephalitis is usually a chronic disease. The so-called sequelæ consisting of the Parkinsonian syndrome, hypertonia, tics, blephorospasms, respiratory disturbances, etc., following the acute stage, are merely manifestations of the infection which has become chronic. These appear at variable times after the acute stage. In fact, we have frequently found patients having unmistakable signs of chronic encephalitis who did not remember having been sick, and did not know they had encephalitis. In some instances, the masked

*Presented before the annual meeting of the Minnesota State Medical Association, Duluth, July 16, 1930.

facies and beginning stiffness, with the peculiar flexed attitude, have been noted immediately after the acute stage. On the other hand these symptoms may not have made their appearance until four years, or longer, after the acute stage.

In considering the treatment of epidemic encephalitis, we are obliged to consider the treatment of two distinct classes of cases: (1) the acute cases; (2) the advanced cases, which exhibit the Parkinson syndrome or mental symptoms.

The treatment must necessarily vary in the consideration of these two groups, for in the first we are dealing with an acute infection accompanied by inflammation and exudation, while in the second group we are dealing with symptoms which exist, due to organic and degenerative lesions in the brain, as a result of acute infection and inflammation.

The acute cases.—The treatment of the acute cases is best managed by hospitalization, with exclusion of all visitors and members of the family, and allowing as complete mental rest as is possible. There should, of course, be skilled nursing care. Febrile symptoms and restlessness are controlled in the usual manner, with baths and the use of ordinary sedatives such as would be used in any acutely sick case. Spinal drainage is useful, particularly in cases where markedly increased spinal fluid pressure is observed. Drainage of the spine may be made daily or less often, as the individual case seems to warrant. Lumbar puncture is performed in the usual manner and the spinal fluid allowed to drain until the pressure is reduced to normal. The amount of fluid removed at each drainage is of no particular consequence, and varies in the individual case, as well as in different cases. The usual amount removed at a single drainage is from one-half to one and one-half ounces, depending upon the degree of increased pressure. One observation we have made is that in cases where the spinal fluid pressure is markedly increased, the prognosis is much brighter than in those cases where there is a normal or decreased pressure.

In the hemorrhagic type of case, spinal drainage may be made as often as twice in twenty-four hours to relieve intracranial pressure. The examination of the spinal fluid is always of value in determining the progress of the case, particular attention being paid to the rise or fall of the cell count in the fluid.

Specific medication, unfortunately, is lacking in the treatment of epidemic encephalitis. Assuming this disease to be caused by a bacterial virus, the logical route of attack is by means of intravenous therapy with virocidal remedies. To this end, various intravenous medications have been used, such as: sodium salicylate, mercurochrome, sodium iodide, neutral acriflavine.

The sodium salicylate treatment has been advocated chiefly by French clinicians, and as administered by them consists in daily intravenous injection of sodium salicylate in large doses. A solution of ten or fifteen per cent is used and the patient receives a daily injection, varying from two to five grams of sodium salicylate. We have never seen any particular benefit from this treatment. Venous thrombosis is particularly apt to occur following this administration of sodium salicylate, and no startlingly good effects have been observed. It is quite probable that just as much good would be accomplished with large doses of sodium salicylate given by mouth.

Intravenous use of mercurochrome we have tried very thoroughly, using a one per cent solution, and have found it to be of no value whatsoever.

Likewise, sodium iodide has proven inefficient in these acute cases. Of all the various forms of therapy, we subscribe solely to the use of neutral acriflavine, with which we have treated a large number of cases, with surprisingly beneficial results in a large percentage of those treated. Briefly, the technic for the use of acriflavine is as follows: The recrystallized and repurified salt is used, the commercial product being unfit for intravenous injection. The solution to be injected must be prepared freshly, each day, and must not be allowed to stand for any length of time in the light, because it is very unstable and breaks down readily. The solution prepared is one-half of one per cent in strength. Of this, 10 c.c. are injected intravenously every day for ten consecutive days. The injection must be made very slowly, taking about five minutes to inject the solution. If given too rapidly, there will be a marked respiratory reaction, which, while not at all dangerous, is a matter of great discomfort to the patient. During the injection there will be noted a flushing or mottling of the skin, lacrimation, and possibly sneezing or

vomiting. These symptoms are of no consequence whatsoever, and do not warrant interruption of the treatment. Great care must be used to have the needle in the vein, for extravenous infiltration of the tissues with the solution of acriflavine will always cause an acute local reaction and a sloughing of the tissues so infiltrated. After the first series of ten daily injections is completed, a period of rest for eight to ten days is given, and then a second series of injections is used in the same manner. A third series may be used after a second rest period, if it is deemed necessary.

In a large series of cases treated by the above described method, during the last four years, not a single adverse effect has been observed. Marked recession of clinical symptoms, both subjective and objective, has been observed in a large percentage of cases. In several cases this treatment has acted with almost the same specific effect as diphtheria antitoxin, causing a very rapid and complete recession of symptoms, with recovery of the patient. Marked reduction in spinal fluid cell counts has been observed. In one instance the spinal fluid cell count of approximately 500 lymphocytes was reduced to less than 200 lymphocytes after three injections. Improvement, if it occurs, usually begins after the third or fourth injection of this drug.

The advanced cases. — Unfortunately, the treatment of advanced cases of epidemic encephalitis, particularly those which exhibit the Parkinson syndrome, is still in the experimental stage. Nothing curative can be done for these patients. Various forms of treatment have been used, with varying degrees of success. The fact that these patients show symptoms which are indicative of organic and degenerative lesions in the brain makes a cure out of the question. Relief of symptoms is the most that can be hoped for. The management of this type of case includes, briefly, the following:

Removal of foci of infection, particularly in the teeth, sinuses and throat.

Careful regulation of elimination.

Proper regulation of diet, with attention to the general nutrition of the patient.

Physiotherapy, such as general massage, warm baths, and the use of diathermy.

Control of the life of the individual, to promote as far as possible emotional balance.

In addition to the above, various forms of medication have been used, with varying degrees of success. Stramonium is highly recommended in the form of powdered dry leaves. It is administered in capsule form, beginning with a dose of one grain three times a day, increasing the amount one grain a day until a maximum of fifteen grains a day is given. The dose is then decreased, gradually, until a dose of eight grains a day is reached, which is maintained for a week or ten days. A period of rest of a few days is then given and the procedure repeated.

In our experience, the greatest benefit has been given these patients by the use of tincture of belladonna, administered by mouth, for purposes of controlling sialorrhea. An initial dose of three drops three times a day is increased by one drop a day until the point of tolerance is reached, as shown by symptoms of belladonna poisoning. Patients often reach a maximum of thirty drops, three times a day, before having to discontinue this drug. In addition to this, intravenous acriflavine, as outlined above, and intravenous sodium iodide, 31 grains, three times a week until a point of saturation is reached, have proven useful. Hyoscin in small doses, administered daily, is of use in cases where there is a marked tremor. Unfortunately, little can be accomplished for the average case of this type, and while some temporary benefit may be obtained, lasting results are very disappointing.

The problem of post-encephalitic syndrome is one of the most formidable which confronts the profession today, and it is undoubtedly no nearer solution now than it was five years ago. Institutional care for these pitiful cases seems to be one solution of the problem, and some agitation has already been made for State Institutions to care for these sufferers.

THE SIGNIFICANCE OF TEMPORARY BLINDNESS*

William L. Benedict, M.D.
Rochester, Minnesota

THE loss of any part of one's vision is an occasion for apprehension, and the cause of this loss becomes the object of intensive search. Partial loss of vision, or temporary total loss of vision, is not uncommon as a symptom of disease or disorder affecting the visual pathways, or of a constitutional disease or disorder. Temporary blindness, particularly, intrigues the physician. The absence of pathologic changes on examination of the eyes may be of as much importance as if definite changes were to be found in some portion of the eye, and it is well known that in some cases of temporary blindness the examination gives negative information.

If blindness occurs in the course of an illness, or following a surgical procedure, considerable apprehension may be aroused as to whether the loss of vision will be permanent. Indeed, permanent blindness may occur as a complication in rheumatic fever, Bright's disease, multiple sclerosis, tabes, meningitis, influenza, and in a number of less common acute, chronic, or recurrent diseases. From the effects of emboli following surgical operations in the pelvis, or on the extremities, temporary loss of vision occasionally is encountered, and even permanent blindness has been reported. Procedures apparently as harmless as aspiration of fluid from the pleura may bring on sudden loss of vision, to the consternation of the surgeon and to the dread and alarm of the patient and his friends.

Whether temporary blindness or permanent blindness is to be the lot of one in whom loss of vision occurs is often a matter of the extent to which the process directly responsible has gone. Many conditions which lead to temporary blindness lead also to permanent blindness. If changes in the media of the eye or atrophy of the nerve have been extensive, it can be definitely determined that vision never can be restored. Because of the difficulty in determining whether or not blindness will be only temporary, and because of the necessity for determining the cause early in the course of the affliction, thorough examination in cases of blindness becomes of great importance. For the proper examination of a patient who complains of temporary blindness, there is required a knowledge of the pathology of the eye and the visual pathways; but often it is necessary for the physician to match his wit against that of a malingerer or one who is actually deceived about his own vision. A carefully obtained anamnesis is the first step in the examination. Not only is it necessary to listen to the story of the patient but it is well to get this history independently from relatives or others who have observed him. Loss of vision, without adequate pathologic changes to account for it, is found in persons of nervous instability. The history may be of importance in arriving at a diagnosis.

FUNCTIONAL BLINDNESS

Hysterical amblyopia.—Case 1. A boy, aged eight years, in apparently good health, was the only child of a family that lived in a small Canadian village. He had an abnormally large head, but he had grown up among his playmates, and no mention was ever made of this condition in his hearing. He entered kindergarten and was making satisfactory progress when the parents moved to another part of town and the boy was placed in another school. A few weeks after he had been transferred to this school, he was sent home with a note from the teacher, saying that the boy complained of headaches, and considerable drowsiness, and that he was unable to see writing on the blackboard that was plainly visible to other children in the room.

A general examination failed to show cause for the boy's poor vision. An attempt was made to keep him in school, but the defect in vision increased until he was unable to get about alone. Physicians near his home, unable to understand any reason for his complaint, referred him to specialists in another city. The father was told that the boy had a tumor of the brain, and that in all probability he would never see again. It was because of this diagnosis that physicians at The Mayo Clinic were consulted.

Early in the course of the examination, and after a thorough search had failed to reveal any disorder or disease of the eyes, the father chanced to remark that in the neighborhood in which he first lived the children were very careful never to mention this boy's deformity, so that the boy himself apparently was unaware of any difference between himself and his playmates. After he had entered the new school, he was taunted by his schoolmates with the epithet "big-head," an insult which

*From the Section on Ophthalmology, The Mayo Clinic, Rochester, Minn. Read before the North Dakota State Medical Association, Bismarck, N. D., May 27, 1930.

evidently hurt him and gave him a feeling of inferiority. The defense reaction of this child was to remove himself from the children who would hurt him and his chief defense took the form of hysterical blindness.

The boy was under observation for one week while he was at the clinic with his father and enjoyed the privilege of frequent visits to the zoölogical park and other places of interest. Complete vision was restored merely by a change of environment.

Comment.—Hysterical amblyopia, sometimes spoken of as retinal anesthesia, is functional blindness without pathologic change of the eyes or visual pathways. It is more common among women than men, and more common among young persons and children than older persons. It is not infrequent among girls in their teens who find some difficulty in adjusting themselves to disagreeable social circumstances or exaggerated parental solicitude. It is always bilateral, usually gradual in onset, and unassociated with headache, pain, or constitutional disease. The diagnosis is often suggested by the history, and is established by elimination of pathologic processes. It is confirmed by the restoration of good vision, by whatever effective means may be adopted. In some cases, I believe hysterical blindness becomes permanent.

It is essential, in the treatment of hysterical amblyopia, that one of two things be brought about: that the conditions under which the amblyopia developed should be changed, or that a situation be substituted which is more intolerable than the first. Most patients with hysterical amblyopia will recover their vision if kept in isolation, with their eyes bandaged and on a milk diet. In treatment of young persons, it is necessary that only such attention as is necessary be provided and that the company of parents or other visitors be not allowed. Two weeks of such isolation is usually sufficient to bring about restoration of vision. Recurrences among young persons are rare. Substitution neurosis may appear, but if steps are taken to correct the original cause of the disturbance, useful vision as a rule is maintained.

Amblyopia associated with migraine.—This type of functional neurosis is much more difficult to understand and far more difficult to treat. The blindness may take the form of scotoma, of hemianopsia, or even of complete blindness. The blindness usually precedes a severe migrainous headache, and may persist for hours or days after the headache has disappeared. Frequently, warning of the onset of blindness is given in the form of aura or floating spots before the eyes. Mild cases proceed no farther than scintillating scotoma or subjective sensations of flashes of light. In such cases not all attacks of migraine are associated with amblyopia, but severe attacks of headache, with some degree of blindness, may be frequent and often periodic. Although they are more common in persons about the age of fifteen to twenty-five, they may persist well beyond the age of fifty.

There must be other criteria, however, sufficient to establish the diagnosis of migraine, before one can assume that blindness associated with headache is not significant of organic disease. I have seen total permanent blindness of one eye that seemed to be due to repeated attacks of migraine.

BLINDNESS DUE TO PRIMARY DISEASES OF THE EYE

Glaucoma.—Temporary blindness is an early and frequent sign in simple glaucoma. Transient, high intraocular tension brings about definite reduction in vision through cloudiness of the cornea. The cloudiness clears away, with restoration of vision when the tension is reduced. As the glaucoma is usually limited to one eye, the blindness is also limited to one eye. I have had under observation a patient whose intraocular tension could be changed at the will of the physician from less than normal to more than five times normal, by the alternate instillation of homatropine and eserine. With each rise of tension, the vision would be reduced so that only perception of light remained. When the tension was reduced, vision came back to 6/5. The condition was limited to one eye. The glaucoma, however, could not be controlled indefinitely by miotics; so it became necessary to resort to operation to bring about permanently low tension. The more frequent attacks of hypertension from which the patient had suffered caused partial atrophy of the optic nerve, and partial permanent loss of vision in the eye resulted. It is possible for a person to have a marked increase of tension in both eyes at the same time, with marked reduction of vision. Careful examination of the eyes during the time when vision is poor will clearly reveal the diagnosis. Treatment instituted early in the course of the disease often

may save considerable vision which otherwise would be permanently lost.

Interstitial keratitis.—One of the most alarming inflammations of the eye, as well as one of those which gives a good prognosis, is interstitial keratitis, an inflammation of the cornea of children and young adults afflicted with hereditary syphilis. Although it is usually found in children between the ages of eight and sixteen years, it sometimes appears earlier in childhood. One eye is affected a few days to a few weeks in advance of the other, but both eyes are always affected, usually to the same extent. The second eye will become involved in spite of the most vigorous efforts to ward off its involvement. Hereditary syphilis often is not recognized until the onset of keratitis and frequently it becomes the duty of the oculist to investigate the family for other evidences of the disease, and to inform the parents of the seriousness of the malady. Delayed keratitis, occurring after the age of twenty-five years, may run the same general course as keratitis in younger persons, but appears to be more protracted. The end-result is the same. The acute stage lasts for six to ten weeks. During this time the patient is temporarily blind, with photophobia and lacrimation. During convalescence there is little, if any, pain, but light is poorly tolerated, necessitating the use of dark glasses until the cornea is clear. The prognosis as regards vision is good.

Keratitis associated with conjunctivitis is sometimes a complication of the exanthematous diseases, particularly measles, scarlet fever, and smallpox. Here the disease frequently takes the form of corneal ulcers which leave white scars in the cornea, a permanent obstruction to vision.

DISEASES OF THE OPTIC NERVE

Inflammation of the optic nerve is a common cause of temporary blindness, seen most often as a unilateral affection, and appearing as a complication in a large number of general conditions and a few local diseases. Optic neuritis is always accompanied by reduction in vision when it eye. Indeed, the cloudiness of vision may be the occurs in a previously healthy and functioning first symptom noticed by the patient. Although usually bilateral, it may be unilateral or alternating. It may be secondary to disease in the proximity of the optic nerve, although it is often metastatic from some chronic local or constitutional inflammation.

Syphilis.—Probably the most common cause of optic neuritis given in the literature and texts of twenty-five years ago was syphilis. Whatever the relationship was considered to be at that time, I am sure that it will not hold today. There are several reasons why we have to revise our ideas regarding the rôle of syphilis as one of the common causes of blindness, both as regards the optic nerve and the anterior segments of the eye. Let us not forget that in the last twenty-five years the Wassermann reaction has aided tremendously in determining the presence or the activity of syphilis, and that the diagnosis of syphilis in the face of repeatedly negative Wassermann reactions must be supported by a preponderance of positive evidence. Then, too, syphilis is recognized earlier and treated much more effectively than it was a few years ago. It is not uncommon, now, for the disease to be arrested before it reaches the secondary stage, and tertiary syphilis, except in forms of disturbances of the central nervous system, is rarely seen. Seldom is optic neuritis seen as a complication where large numbers of cases of primary and secondary syphilis are seen. It is asserted that the race is becoming immune to the disease and that it is noticeable in European as well as in American clinics that the severe secondary and tertiary lesions of syphilis, once so common, are conspicuously absent. Optic atrophy, or ocular tabes, still takes its toll in blindness, but there the loss of sight is permanent and not unexpected, for it occurs in about 10 per cent of the cases of syphilis of the central nervous system.

Retrobulbar neuritis.—The greatest controversy among oculists over optic neuritis rages about the causes of retrobulbar neuritis. This term should be applied only to those cases in which there has been a marked loss of vision, central scotoma, and retardation of pupillary reflex, without change in the optic disk or other obvious disorder of the globe or the media. The only symptom is loss of vision, of rapid onset unaccompanied by pain. Examination of the visual field will reveal a large central scotoma, loss of perception of color, and rise in the threshold of perception of light. In other words, there is a block along the conduction path of the retinal fibers, particularly in the macular bundle. It has been agreed that this block may be brought about (1) by pressure from an extraneural source, such as bulging sinuses, abscesses, tumors, or hemor-

rhages; (2) by local inflammation within the nerve or the nerve sheath through direct extension or possibly through metastasis, and (3) by toxins. If pressure from an extraneural mass can be demonstrated there is, in all probability, an answer to the question of the cause of the retrobulbar neuritis. The chief difficulty, however, has been to show conclusively that such pressure does exist in the absence of clearly demonstrable tumor and abscesses. Disease of the nasal accessory sinuses is held by a large group of outstanding oculists to be of such importance in retrobulbar neuritis that, regardless of rhinoscopic data and interpretation of roentgenograms, they will direct the opening of the paranasal sinuses by the rhinologist, and will assume all responsibility for the procedure, in the mistaken notion that ventilation and drainage of an apparently normal sinus is adequate to restore vision. A list of such cases can be supplied at will which on first consideration seem to support the argument that early surgical invasion of the sinuses is followed by restoration of vision in a few hours to a few days, and hence lends support to the theory that the retrobulbar neuritis in that case was due to disease of the sinuses. However, febrile treatment must be considered: foreign protein, without surgical invasion of the sinuses, has been used with equally good result. If it is necessary to ventilate and to drain the sinuses, how can the effect of protein therapy be explained? If equally good results are obtained, is it not better practice to use nonsurgical treatment and to avoid postoperative changes in the nose, that in themselves may give rise to discomfort and even disease?

It often has been demonstrated that a common cause of retrobulbar neuritis is multiple sclerosis, a disease of the nervous system that probably has no relation to any disease of the sinuses, although the rôle of focal infection in the production of multiple sclerosis is not clearly understood. Multiple sclerosis is a disease of young adults who often are apparently in good health. The symptoms, in mild cases, often are difficult to elicit and the disease may run for years before a satisfactory diagnosis can be made. In every case of retrobulbar neuritis in a young adult, multiple sclerosis should be thought of first, and in the absence of perfectly obvious causes of another nature, the treatment should be carried out along medical lines. Retrobulbar neuritis may be the only outstanding symptom of multiple sclerosis for years. I have recently seen, in a woman aged twenty-six years and in a man aged thirty-three years, the second attack of retrobulbar neuritis after ten years, with no ocular disturbance in the interim, and with gradually developing signs of multiple sclerosis during the last few years. In each case, vision was reduced barely to perception of light in one eye at the beginning of treatment and was restored to 6/6.

Almost complete blindness in one eye may be accompanied by partial blindness or hemianopsia in the other eye, a circumstance that may escape notice unless the visual fields of both eyes are carefully tested. Temporary blindness of one or both eyes, without change in the globe or disk, is most likely to be due to retrobulbar neuritis, but this diagnosis, once made, rarely should be used as an excuse or a reason for surgical invasion of the paranasal sinuses in the absence of visible pathologic change in the nose.

EMBOLISM, TOXEMIA, AND TOXICOSIS

It may seem rather incredible that sudden blindness should follow a simple procedure like thoracic puncture for pleural effusion; yet there are a number of authentic recorded cases. If an open cannula is employed in the puncture, air may be introduced into the veins, which, during a part of respiration, are under negative pressure. The general symptoms of air embolism, such as apprehension, fear of impending death, faintness, suffocation, and blindness, all come on suddenly, much to the consternation of the surgeon. The blindness is due to air in the arterioles of the retina, and the consequent ischemia. If only a small amount of air enters the vessels, the blindness may not be complete, and may clear away in a short while. I know of no case of total, permanent blindness from that cause.

Embolism of the retinal arteries is seen in cases of endocarditis and general vascular disease, including arteriosclerosis, more often, I think, in persons aged more than fifty years. Thrombosis of the retinal veins is probably seen as commonly as a result of arteriovenous compression or of disease of the wall of the vessel. There results infarction of the retina, with edema, hemorrhages, and exudates. A scotoma subtends the affected part of the fundus. If the central vessels of the optic nerve are occluded, permanent, total loss of vision results. In the toxe-

mia of pregnancy there sometimes occurs such edema of the retina that vision is reduced to the bare perception of light. The pathologic change is probably not limited to the retina, but involves the optic nerve in more or less severe optic neuritis, which may leave the patient totally blind if it persists for several weeks. In the active stages of retinitis, the choroid coat may be temporarily detached by serous exudate. I have seen two such cases with recovery of vision after elimination of the cause of the toxemia. Neuroretinitis, following miscarriage and subsequent uterine infection, may be followed by almost complete blindness, and constitutes one of the hazards of induced termination of pregnancy. Yet it sometimes becomes the duty of the oculist to decide, in a case of marked involvement of the eye in toxemia of pregnancy, whether vision can be restored without emptying the uterus. If pregnancy complicates multiple sclerosis, the issue is generally fatal. With the splendid prenatal care that most mothers now receive, the combination of toxic nephritis, high blood pressure, and albuminuric retinitis is less seldom seen. If the retinitis occurs late in the seventh month of pregnancy, expectant treatment may be adopted with a moderate degree of safety from permanent blindness, although every possible means should be adopted to combat the toxemia. In case of intractable hypertension, with albuminuria and retinitis, it is doubtful if many patients regain much of their vision if the condition has existed for more than six or eight weeks. Consideration of the termination of pregnancy is the only alternative to almost certain blindness in such cases, and must be undertaken, if at all, before irreparable injury has been done. In one patient under my observation the systolic blood pressure was lowered more than 100 points in twelve hours after the uterus had been emptied, and the retinitis began to clear away within a few days. Normal vision was restored after four months. It is the province of the general physician to determine the probable hazard of future pregnancies in women who have suffered retinitis with toxemia, but it is well known that women who have partial permanent blindness as a result of toxemia of pregnancy have gone through subsequent pregnancies without suffering the same complications.

If I were to mention all of the conditions which may be complicated with temporary blindness it would be merely to catalogue a number of them that are rarely encountered, or that are so well known that any further comment is uncalled for. Except in industrial centers, where factory workers are exposed to poisonous products, impure alcohol and tobacco probably head the list of poisons that produce blindness in varying degree. Quinine taken in large doses, as an ecbolic, will produce optic neuritis, with subsequent partial or total atrophy of the optic nerve. In ordinary doses, such as are given in the treatment of malaria for instance, it is a safe drug. The arsenicals, used in the treatment of syphilis of the central nervous system, particularly general paresis, have been suspected of producing optic atrophy. Further study of the effects of these drugs, however, would seem to indicate that only those patients who would have lost their vision through the disease had no treatment been given, have gone on to blindness. The drugs, administered in the same doses to persons free from disease of the central nervous system, have no effect on the eyes. It seems probable, therefore, that not the drugs, but the disease for which the drug is administered, must be held to account for blindness in cerebrospinal syphilis. The ocular conditions following injuries, diseases of childhood, septicemia, focal infections, constitutional diseases such as syphilis, tuberculosis, diabetes, anemia, toxemia from chemicals and drugs, hypertension, nephritis, tumor of the brain, and a host of otherwise insignificant disorders which may terminate in partial or complete temporary blindness, constitute an interesting chapter in the history of medical investigation and practice. Everyone who is engaged in the practice of medicine is concerned with the diagnostic signs revealed by the ophthalmoscope and the perimeter, and the well trained oculist is a most valuable consultant.

CIRCULATORY TESTS PREVIOUS TO AMPUTATION*

William T. Peyton, M.D.
Minneapolis

THERE have been a number of tests recently developed to test the efficiency of the circulation in the extremities, but according to McKittrich and Root (1928), "At present no simple, practical, and accurate laboratory or clinical test is available by which the degree of circulatory disturbance in a given foot can be measured or by which the point at which amputation should be done is indicated. . . . Fortunately the patient usually gives sufficient clinical data to warrant an estimate of the circulatory condition of the foot sufficiently accurate for intelligent treatment."

Still some of these tests are of value in early diagnosis, in the differential diagnosis of these conditions, and also in giving corroborative evidence of the degree of circulatory disturbance. An attempt has been made in this paper to collect the various tests which have been proposed.

HISTORY

Frabricius Hildames (1560-1624) advised amputation at an early stage in gangrene and he advised that the incision should be made in the sound, and not in the decayed flesh.

Pott (1785) gives a good description of arteriosclerotic gangrene to which little could be added today. He states, "It frequently happens to persons advanced in life, but is by no means peculiar to old age. . . . It has by some been supposed to arise from an ossification of vessels, but for this opinion I never could find any foundation but mere conjecture." He advised allowing gangrenous toes to drop off of themselves.

Charcot (1856) called the fatigue and pain on exercise "claudication intermittente." Maurice Raynaud (1862) was the first to maintain that gangrene could occur without vascular occlusion. Billroth (1869) in speaking of arteriosclerotic gangrene said that we must amputate in the thigh as soon as the popliteal artery pulsation cannot be felt. Winiwarter (1879) used the terms "endarteritis" and "endophlebitis" in describing the condition of a man aged 57 with obliterative arterial disease of the extremities. From his description of the vessel pathology it is now evident that this was thromboangiitis obliterans. König (1887) first demonstrated that good results were obtained under careful aseptic operation in diabetic patients. Results were bad previous to the advent of aseptic surgery because the resistance of the tissues in the extremities was so low as a result of poor circulation. Marshall di Calvi was the first to call attention to the frequent relationship between diabetes and gangrene. Landlow (1892) described a large number of favorable results in senile and diabetic cases where a more distal amputation than through the thigh was done. Heidenhain (1891) so long as the gangrene involved the digits only, awaited a line of demarcation, but if it involved the foot he amputated every case above the condyles of the femur. In doing this he was influenced by the bad results he saw in lower amputations performed by Küster, but Küster also adopted a more proximal site for operation later. Buerger in 1908 established as a pathological entity the condition now often called Buerger's disease and called it obliterating thrombo-angiitis.

CLINICAL HISTORY

Some special features should be stressed in taking the history of these patients. What were the precipitating factors? Was it exposure to cold? Was it injury? Did it occur without any known precipitating cause? Is there abnormal fatigue in any part of the extremity? How much exertion is necessary to bring on this fatigue? Is there claudication? Is there rest pain? Have there been color changes, vasomotor disturbances, or phlebitis?

PHYSICAL EXAMINATION

Final opinion will be based largely upon physical findings. The following conditions should be looked for:

1. General appearance of the limb.
   a. Dry scaling atrophic skin.
   b. Irregularity of the nails.

*From the Department of Surgery of the University of Minnesota. Presented before the annual meeting of the Minnesota State Medical Association, Duluth, July 15, 1930.

2. Rubor or cyanosis when the limb is in the pendant position.

3. Ischemia on elevation of the limb.

4. The absence of some or all of the usual arterial pulsations. Single pulses eluded detection in less than 1 per cent of 700 ward cases examined by Erb's assistants. One case (0.5 per cent) in 200 supposedly normal individuals was found by Buerger where the dorsalis pedis artery could not be elicited. An apparently normal foot without pulse in the popliteal space or below the groin means a highly developed collateral circulation. It is uncommon and means that gangrene is impending.

5. The angle of circulatory efficiency should be determined. The extremity is raised to a vertical position and if it does not become ischemic the angle of circulatory efficiency is zero. This is the result one should obtain if the circulation is normal. If the foot becomes ischemic the limb is gradually lowered until it assumes the normal pink color. The angle of circulatory efficiency is that through which it has been lowered. The magnitude of the angle increases in direct proportion to the impairment of the circulation.

6. Search should be made for phlebitis. Recurrent phlebitis of the superficial veins is frequent in thrombo-angiitis obliterans.

7. The temperature of the skin should be roughly determined by feeling with the hand. In severe circulatory disturbance the skin of the distal portion of the extremity will be appreciably colder. Abrupt change is felt in sudden occlusion with poor collateral circulation.

8. Changes in the extremity following heat and cold should be noted. In Raynaud's disease the appearance and circulation is entirely normal between attacks but cold will precipitate the attack.

After this examination has been completed one should perform any of the special tests which are indicated. The tests regularly used in this clinic are the determination of the oscillometric index, the salt solution test of McClure and Aldrich, and the Moszkowicz test for spread of hyperemia after temporary interruption of the circulation. The surface temperature is determined with a thermocouple only in special cases, for example, in thrombo-angiitis obliterans where lumbar sympathectomy is contemplated. Other tests have not been used, or rarely used, but are described in an attempt to collect all the various tests which have been proposed to determine the efficiency of the circulation in senile or diabetic arteriosclerosis, or in thrombo-angiitis obliterans. These tests are listed not according to their importance but in chronological order of their development.

Palpation for pulsation to determine the site of amputation was mentioned by Billroth in 1869. Palpation of the pulse and the sphygmograph was employed by Gussenbauer, but he concluded that it was not reliable.

Moszkowicz described in 1907 the test now known by his name. It is based upon the fact that a hyperemia occurs after temporary interruption of the circulation. An Esmarch rubber bandage is applied beginning at the distal end of the extremity and wrapping in a proximal direction until the entire extremity is bandaged and compressed by this bandage to express practically all blood, both venous and arterial, from the limb. The bandage is then allowed to remain in place for five minutes or more, when it is removed in the distal to proximal direction. The area is ischemic immediately after removal of the bandage, but this is followed by a hyperemia appearing uniformly over the bandaged area in about a minute or less in the normal individual. In the patient with circulatory disturbance this hyperemia creeps down the extremity and appears in normal time in the proximal portion, where the circulation is adequate, but below this level it spreads more slowly and irregularly. The greater the impairment of the circulation, the more slow the spread of hyperemia. Adequate collateral circulation, if present, gives a normal reaction, regardless of the condition of the main artery.

The explanation of hyperemia is not clear. Paralysis of vaso-constriction has been suggested. Moszkowicz thinks it is excessive flow following damming back. From injection experiments, Moszkowicz concluded that the arterial occlusion should be at the site of the hyperemia or a few centimeters higher. These injection experiments consisted of intra-arterial injections of colored dyes above a ligation of the artery and he noted the area of skin colored by the dyes.

To amputate 5-10 cm. above the line of hyperemia is prudent. The skin flaps are best taken from the side where the hyperemia reaches lowest. By this test Moszkowicz says it is possible to determine, in some cases, where only the toes are gangrenous, that it is safe to await the dropping off of the toe or to amputate the toes or to amputate at the root of the foot. The test is influenced by severe infections.

Wieting (1908) left both limbs bare for fifteen minutes, then covered them with bed clothes

for fifteen minutes and amputated at the level of warm skin in the diseased limb.

Delbet (1909) emphasized the fact that absence of the peripheral pulse from any cause without affecting the nutrition or vitality of the extremity means the collateral circulation is fully

Normal readings as given by Samuels (1927) follow:

Upper arm	4-20
Elbow	2-12
Wrist	1-10
Palm	0- 2

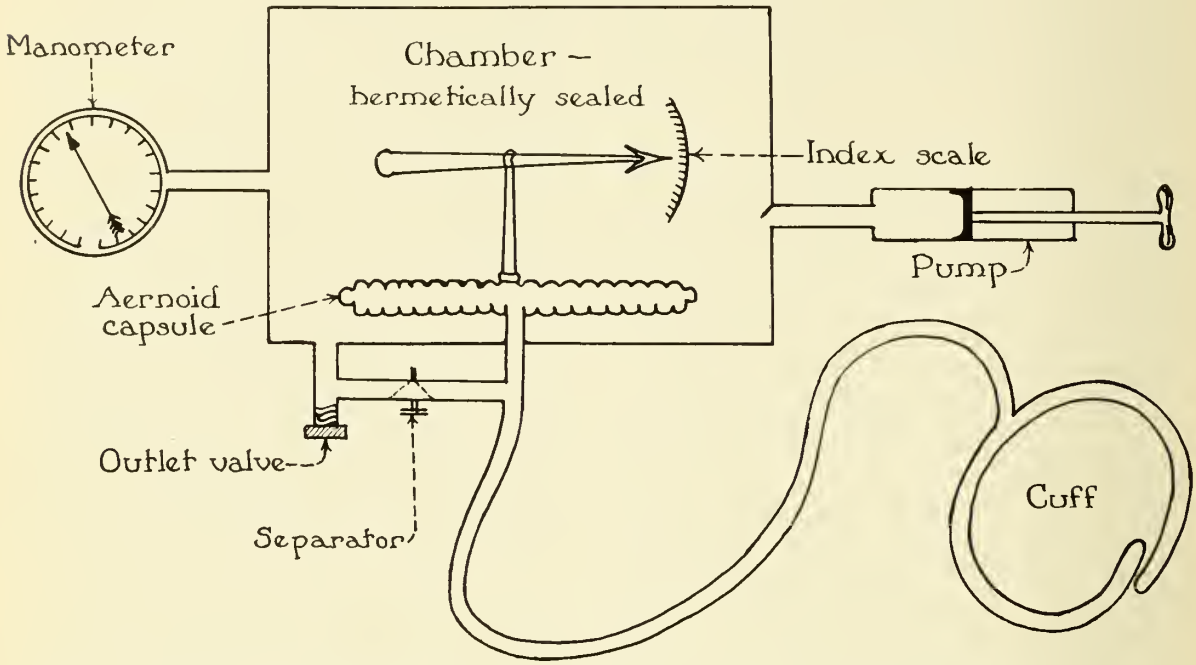

Fig. 1. Diagram of Pachon oscillometer from *Comp. rend. des sc. et mem, de la soc. de biol.*, 1909, Vol. 66.

established. This is particularly applicable to aneurism, tumors, etc.

Pachon oscillometer test (1909): In order that a capsule be constant and of maximum sensibility it is necessary that the capsule shall be without tension. The Pachon oscillometer is so constructed that there is an aëronoid capsule within an outer chamber, the capsule so arranged that the chamber and capsule are in communication and therefore under equal pressure but can be disconnected by a separator while a reading is taken. The reading is called the oscillometric index and is the number of points on the scale over which the needle passes in its excursion. To eliminate false movements due to muscular contraction the patient must be reclining and relaxed. All readings should be made at a uniform pressure for each case. They are best taken at the diastolic blood pressure. Maximum oscillations of the needle are obtained at this pressure. Toward the periphery of the extremities there is a normal decrease of the index.

Thigh	4-16
Upper third of leg	3-12
Ankle	1-10
Pedal circulation	0.5- 2

Observations by McKittrich and Root on the circulation of the legs of eighteen diabetics are given in Table No. 1.

The amplitude of oscillation theoretically reflects the amplitude of the pulse. Its change should indicate the level of occlusion in the artery.

A marked increase in the oscillometric index in cases of vasomotor spasm was observed by Babinski and Heitz (1916) after immersion of the limb in a warm bath for a period of ten minutes, but this change was not evident in true occlusive lesions. A marked increase in the oscillometric index in cases of vasomotor spasm was also observed by Oelentz and Cornil (1919) after the application of an Esmarch bandage for five

minutes, but it did not occur in organic vascular occlusion.

Physical limitations in the instrument, according to Samuels, are (1) inability to select any one vessel for study and (2) insensibility to that state of the circulation represented as lying between zero and total cessation of flow.

$$Q = \frac{H}{T - T_1} \cdot \frac{1}{S}$$

Q = Blood in grams
H = Heat given off
T = Temperature of arterial blood
T_1 = Temperature of venous blood
S = Specific heat of blood

The heat loss from the surface of the extrem-

Table No. 1.

Normal 4	6.5	4.0	5.0	4.0	4	0	0	0	0	4

No information regarding the extent of the collateral circulation is given by the oscillometer, therefore, one may have a living foot with a zero reading. The force and character of the cardiac contractions affect the oscillations. After following with the oscillometer for the purpose of determining the prognosis the course of 124 cases of thrombo-angiitis obliterans for periods varying from three months to four and one-half years, Silbert and Samuels (1928) concluded that when the oscillometer shows pulsation at the ankle the prognosis is good, even if ulceration or gangrene is present.

Particularly useful to determine safety of ligation of a vessel is the Tuffier and Hallion test (1912). For this test, to obstruct venous return of blood causing turgescence an elastic circular band is applied. Collateral circulation is established if this turgescence recurs after compression of the artery or arteries of the extremity. This test is not applicable where there is swelling.

Stewart (1913) described the heat elimination test. Heat produced in an extremity is negligible in comparison with that conveyed to it by the circulation. The temperature of the incoming blood is known and that of the outgoing blood is taken to be the temperature of the skin. The amount of heat given off in a known time is measured. The "volume per minute flow" can then be computed with the following formula:

ity for a given period of time was measured by Brown, Allen and Mahorner (1928) with the Stewart calorimeter as modified by Kegerreis. The loss of small calories per minute per square inch was calculated. To interpret this in terms of volume flow of blood is not possible because there are too many unknown factors to attempt a quantitative estimation of this relationship, but it is not essential. The relationship between blood flow and heat loss, however, is very close. At room temperature of 22 to 28° C. normal persons lost per minute 0.46 to 1.15 calories per square inch of body surface. In patients with thrombo-angiitis obliterans the rate of heat loss varied from 0.27 to 1.13 calories per minute for each square inch of body surface.

With a thermocouple applied to the skin Brown, Allen and Mahorner (1928) measured surface temperature at a room temperature which varied from 22 to 26° C. From the trunk to the distal areas of the hands and feet the temperature decreases. The normal temperature of the foot was found to vary between 24 and 35° C. In patients with thrombo-angiitis obliterans the temperatures were approximately the same. That skin or surface temperature per se is not, therefore, a good indication of arterial insufficiency is apparent, since the findings in both the normal and pathologic subject may be the same.

But in the skin temperature increase of the affected limbs, after administration of a foreign protein to produce vaso-dilatation, lies the essential difference. The surface temperature variations following increases in body temperature as a result of foreign protein injection give information regarding the extent of vaso-dilatation and can be employed in place of the more time consuming method of the study of the rate of heat elimination. To perform this test the body temperature and the surface temperature are determined. Foreign protein in the form of typhoid inoculation sufficient to give chills and fever (80,000,000 to 100,000,000 bacteria) is injected intravenously and changes in body temperature and surface temperature are followed. The amount of vaso-dilatation that can be produced in the collateral circulation is determined by this method.

The increase in surface temperature is 3–10° C. in normal individuals. The vasomotor index is $V_1 = \frac{ST—BT}{BT}$, where ST is the increase in surface temperature, expressed in degrees Centigrade, BT is the increase in systemic temperature, expressed in degrees Centigrade. $V_1 = 1—10$ in subjects without arterial occlusion, according to these investigators; in subjects with thrombo-angiitis obliterans it was $V_1 = 0—6.5$. Lumbar sympathectomy is not advised according to Adson and Rowntree unless V_1 is greater than 2.

A subcutaneous thermocouple was inserted (usually into the great toe) 6 mm. under the skin surface by Brooks and Jostes (1924). The temperature is determined, then a tourniquet is applied for 10 minutes. The original temperature varies widely in normal subjects but there is a uniform fall in temperature with the application of the tourniquet followed by an immediate and rapid rise after its removal. In subjects with known arterial obstruction the temperature fell during the period the tourniquet was on and following its removal the rise was delayed, the temperature continuing to fall for from two to seven minutes after removal of the tourniquet and in most cases the rise was less rapid.

The salt solution test of McClure and Aldrich (1923): From the base of the great toe up the leg at four inch intervals 0.2 c.c. of 0.8 per cent aqueous solution of sodium chloride is injected intracutaneously. Isotonic salt solution is used because it is less painful than water. This test was first used by McClure and Aldrich in normal children and those with edema of nephritis. In those with edema the time of absorption was shortened and the onset of edema could be predicted by earlier absorption. Disappearance of edema for a few days before its actual disappearance could be predicted by slower absorption. After having read the publications of McClure and Aldrich, Cohen used the test in 1925 to determine the adequacy of the arterial circulation in the extremities in cases of arterial disease associated with pain, vasomotor disturbances and even gangrene. He stresses the value of the test in giving evidence of oxygenation and nutrition of the tissues, *i.e.*, he thinks it estimates these conditions more accurately than does volume of blood flow. He demonstrated that the wheals disappear earlier immediately after ligating the single vessels of the thigh but very much more rapidly if the entire thigh had been constricted for one hour. Experience with this test in 97 cases was reported by Stern and Cohen (1926). The normal time for disappearance of the wheals was found to be approximately 60 minutes. But readings as low as 30 minutes at the base of the toe have been considered as normal. In cases with edema the test is not to be relied upon because edema regardless of the condition of the circulation causes a reduction in the absorption time. These investigators check their findings with the oscillometer.

Intra-arterial injection of sodium iodide solution was reported by Brooks (1924). He dissolved 100 grams of sodium iodide crystals in 100 c.c. of distilled water. It was sterilized and injected into the femoral artery, which had been exposed by arteriotomy. The venous flow was obstructed by a tourniquet at the thigh. Distal to a clamp on the artery a needle was inserted into the artery and 10 c.c. of sodium iodide solution injected. An *x*-ray film was made of the extremity. Because the patients had severe pain while the arteries were filled with the solution a general anesthetic was given. The pain was relieved as soon as the obstruction to the circulation was removed.

The compression test described by Allen (1929) consists of manual compression of either the ulnar or radial artery to demonstrate

occlusion of the other. With the artery compressed the patient closes his fist firmly. Pallor results after the grip is relaxed. With the artery still compressed this pallor remains if there is occlusion of the other vessel; hyperemia quickly displaces the pallor if the other artery is normal. This hyperemia gradually fades to the normal color.

DISCUSSION

Good clinical judgment must be relied upon in the final analysis. The Moszkowicz test, the skin edema test of McClure and Aldrich, and the oscillometric index may be easily determined with a minimum risk to the patient and should therefore be employed. There is some slight danger of thrombosis in the Moszkowicz test and of infection in the salt absorption test. McKittrich and Root have not found the oscillometer of great practical value except as an aid in the early diagnosis of arterial occusion. Palpation of the arteries and careful consideration of the symptoms alone is sufficient in 90 to 95 per cent of the cases according to Brown, Allen and Mahorner.

SUMMARY

1. The tests which have been proposed to test the efficiency of the circulation in arteriosclerosis, senile or diabetic, and in thrombo-angiitis obliterans are collected and briefly described.

2. The oscillometric index can be taken and the skin edema and Moszkowicz tests can be most easily performed with a minimum risk to the patient. The information obtained is of value when used to supplement the history and physical findings.

RECURRENT LYMPHANGITIS*

William H. Goeckerman, M.D.
Rochester, Minnesota

THE term, "recurrent lymphangitis," as used in this paper covers all the pathologic conditions that are known under the names, "recurrent erysipelas," "erysipeloid," "lymphedema," "elephantoid fever," and "solid edema." These terms often are used loosely. In the stricter sense, the term erysipeloid probably should be applied to and restricted to the type of erysipelas which is seen in persons who are brought into contact with hogs and other domestic animals, and which is due to the *Bacillus murisepticus*. The term, lymphedema, should be restricted to stasis of lymph as the result of mechanical obstruction; for instance, the obstruction following radical amputation of the breast without infection. The term, solid edema, is better restricted to the end process of recurrent lymphangitis in certain situations. The preceding lymphangitis may have been a process of very low grade in such cases. But in this country, the various terms are often used interchangeably, and I shall, therefore, include them in the term, recurrent lymphangitis.

Recurrent lymphangitis varies markedly in severity; it may be very mild or very severe, with all gradations between. In a typical acute attack, circumscribed areas of skin become hot, red, and swollen. The inflammation is superficial and always recurs in about the same area. The individual attack resembles closely the early stage of erysipelas, and pathologically it is erysipelas, but it differs biologically in that the areas involved are limited and that the attack lasts only a few days. Possibly the background is the development of an allergic state. The local involvement of the superficial lymphatic channels is associated with chills, often a high fever, and malaise. The satellite lymph nodes are practically always enlarged and tender. All these symptoms and signs may be minimal, and some of them may be overlooked if they are not searched for. Gradually the recurrent attacks, even those of the mildest type, lead to fibrosis with considerable thickening of the tissues, and moderate or even pronounced elephantiasis results. It should be borne in mind that very mild attacks of recurrent lymphangitis may lead to a considerable degree of elephantiasis. As time goes on the inflammatory reactions often become less pronounced, but the fibrotic changes, the stasis of lymph, and, therefore, the permanent enlargement and thickening of the involved areas increase. The end stage is permanent and occasionally leads to a grotesque appearance, or even to marked disability. The lids may become so thickened that the patient is practically unable to use his eyes; the upper lip may assume a truncated appearance; the penis may become buried in the folds of an elephentiasic enlargement of the scrotum, and the arms and legs may become so heavy that they are practically useless.

Recurrent lymphangitis is most commonly seen in the lower parts of the legs, the forearms, the eyelids, the nose, the upper lip, the prepuce and the scrotum. It is as yet a matter of surmise why it should have preference for certain anatomic regions, but clinical observation would indicate that these regions represent channels of drainage for atria that are likely to harbor infection. The nose and upper lip probably are infected by way of the nasal and paranasal sinuses and the teeth; the eyelids, through the lachrimal sac; the forearms, secondarily to trauma of the hands, and the lower parts of the legs, because of fissures between the toes, as the result of intertrigo, and particularly as the result of the universal infection with the epidermophyton. It is likely that the scrotal involvement is commonly due to scratching. On other parts of the body, I have seen the condition following vaccination on the upper part of the arm, and following old osteomyelitis of the thumb. Clinically, recurrent lymphangitis, with its subsequent changes in tissue, is sometimes distinguished with difficulty from certain forms of sarcoid, lupus erythematosus, phlebitis, and even a sclerosing syphilide. This difficulty, however, is usually obviated by a histologic examination and by

*From the Section on Dermatology and Syphilology, The Mayo Clinic, Rochester, Minnesota. Read before the Minnesota State Medical Association, Duluth, July 14 to 16, 1930.

observing the clinical behavior for a period of time. The histopathologic changes are essentially those of erysipelas, as would be expected because the process is the result of invasion of the superficial lymphatic channels by the streptococcus, and possibly occasionally by the staphylococcus. There is dilatation of the lymphatic channels associated with stasis of lymph, and pronounced infiltration with polymorphonuclear leukocytes. Later, plasma cells assemble, and definite fibrosis sets in. The seat of the plasmoma is primarily in the lymphatic channels, enclosed in the collagenous substance; the latter gradually becomes hypertrophic. This process eventually leads to the advanced changes of confirmed elephantiasis nostras.

The treatment of recurrent lymphangitis in its earlier stages is a different matter from that in the later stages, when much fibrosis has taken place. The permanent fibrotic changes probably can be removed effectually only by surgical measures, but the recurrent attacks of lymphangitis may pass through many years before any pronounced deformity has occurred. It is during the early years of inflammatory activity that the patient should have treatment to avoid permanent deformity, but it would seem that this stage is very puzzling and that the patient usually has not received any benefit from the measures employed. Fortunately, nature occasionally limits the process by the ensuing fibrosis but usually not until considerable injury to tissue has resulted. It is in the earlier stages that I have seen such gratifying results in a limited number of cases (seventeen) from the use of foreign protein given intravenously, and filtered roentgen-rays applied locally, that I am stimulated to dwell somewhat on the details of the use of these measures.

I have always given the foreign protein in the form of mixed typhoid and paratyphoid vaccine. The dosage has varied from 5,000,000 to 3,000,000,000 typhoid bacilli given at intervals of from one day to a week, and the number of doses from ten to twenty to a course. In several cases, two or three courses were given, each after an interval of several months. The variations in dosage, and so forth, were dependent on the reactivity of the patient, the severity of the process and the patient's response to treatment. Here, as in all forms of treatment, clinical judgment is necessary. The dosage of roentgen rays, of course, had to vary with the area involved and with the type of involvement. It may be recalled that the process affects chiefly the superficial lymphatic structures. This fact ought to enable any expert radiologist to give the proper dosage. Roentgenologic treatment, in this disease, as in others, should be given only by the expert. Therefore, I shall not need to dwell on the factors employed. It has been, and is, my impression that of the two methods of treatment, injection of foreign protein is the more valuable, but that is difficult to decide, for I usually combined the two. I have observed three patients who, I think, did well on foreign protein alone. I do not recall nor do the records reveal any case in which good results followed treatment by roentgen rays alone.

It is not always possible to find the atrium of infection at the time the patient presents himself for treatment of the lymphangitis. However, if it can be found, I am assuming that, in the treatment of recurrent lymphangitis, an effort should always be made to bring about healing of any atrium through which infection might gain entrance to the lymphatic structures. Lesions of epidermophyton of the feet, infected antrums and so forth, should be treated simultaneously with the lymphangitis.

CASE REPORTS

LEG LENGTHENING FOR SHORTENING DUE TO INFANTILE PARALYSIS*

WALLACE H. COLE, M.D.
Saint Paul

Leg lengthening for the shortening due to infantile paralysis was first attempted by Dr. Leroy Abbott, and his reports discuss fully the indications for such a procedure, in addition to showing the feasibility of the operation. Several workers since that time have devised apparatus for accomplishing the lengthening and Abbott himself has several times modified his machine. It is not the purpose of this brief communication to review what is already in the literature or to report a series of cases but merely to again call to your attention the fact that legs can be lengthened and to show the slides of some of the cases treated at the Shriners' Hospital, where satisfactory results have been obtained in paralytic shortenings by an apparatus devised and made at that institution in 1927 and used since that time. The usefulness of the operation is, of course, not confined to paralytic cases only, and shortenings due to congenital defects, injury, tuberculous hips, etc., also can be lessened or completely overcome.

The procedure is a severe one and should not be lightly undertaken, but with proper care there seems to be no reason why children with a marked difference in the length of the legs should not be given the benefit of the operation. The cases shown here all belong to the group where only the leg below the knee has been lengthened, although the thigh can also be elongated by a similar undertaking and with a modification of the apparatus. A lengthening up to 6 or 7 cm. can usually be obtained in the leg proper and this suffices in most cases. The age of the patient, within reason, does not seem to make much difference, as a given increase in length probably means just as much late in life as earlier and 5 cm. gained when 9 years of age is still 5 cm. when adult life is reached. The effect of the operation upon the growth of the bone is not yet known, of course.

The operation, which is performed under a tourniquet, consists briefly of the following steps: (1) tenotomy of the tendo achillis even if this structure is not tight; (2) transverse osteotomy of the fibula in its lower third and sometimes also in its upper third, being sure the periosteum is completely severed; (3) insertion of one modified Steinman pin in the lower end of the tibia and of two pins in the upper end, the three being in the same plane; (4) osteotomy of the tibia into proximal and distal fragments by long longitudinal cuts and two transverse cuts so that the fragments can slide on each other; (5) cutting of all tight fascial and periosteal bands possible; (6) application of the apparatus after closure and dressing of wounds.

The leg is kept at rest for eight to ten days to allow the skin wound to heal and then traction is applied to the distal pin, the two proximal pins being fixed by the apparatus. As a rule the required length can be obtained in about four weeks and when this is accomplished no further traction is attempted. Usually the

*Read as a case report at the meeting of the Minnesota Academy of Medicine, September 17, 1930.

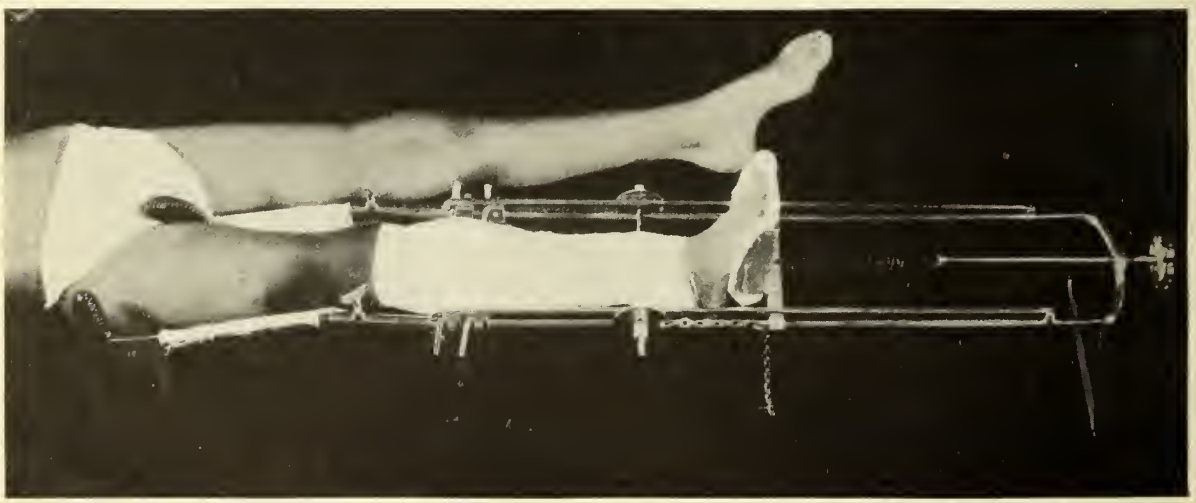

Fig. 1. Leg lengthening apparatus in use. Note the two pins in the upper fragment and one pin in the lower. The footpiece keeps the foot at a right angle, with the pull transmitted through the chains on either side to the distal pin. The centimeter scale is seen as a serrated bar. This shows in the radiographs and gives an exact reading of the lengthening obtained.

INTESTINAL FOREIGN BODIES

REPORT OF FOUR CASES OF REMOVAL BY APPENDECTOMY OR BODY POSTURE CHANGE

FRED H. STANGL, M.D.
St. Cloud, Minnesota

Reports of removal of swallowed foreign bodies have appeared at intervals in the literature. Four cases are herewith added to a list of ten cases reported by various authors. These foreign bodies include glass, nails, wood splinters, paper clips, hair bristle, and tablespoons. They have been swallowed accidentally in some instances, or by insane persons or professional nail and glass eaters. The majority of swallowed bodies are eliminated by the natural passages. When retained, these bodies are usually found in the stomach, the duodenum, the ileum, the cecum, or a diverticulum. Examples of various locations of foreign-body retention are given in the accompanying table. Various surgical procedures were required for the removal of the bodies from the patients listed in the tabulation.

The present report concerns the personal observation of four patients who accidentally swallowed foreign bodies and retained them in the cecum. One was removed by appendectomy and the others by changes in body posture. *Case 1.*—A. L., a male, aged 19, reported that for two or three days he had suffered pain in his right side and that two weeks before, while at work, he had accidentally swallowed a nail and wondered if that could be cause of his pain. The temperature, pulse, urine, and leukocyte count were normal and radioscopy revealed a shadow resembling a flat-headed nail in the region of the cecum. Continued observation revealed, forty-eight hours later, some rigidity of the right rectus abdominis muscle and a leukocytosis of 11,200 with tenderness over the cecum. Laparotomy was then performed. A low right rectus muscle incision was made under nitrous oxide-oxygen anesthesia at 8 a. m. April 6, 1930. The cecum was pulled up at a point where radioscopy indicated the nail shadow. An area of hemorrhagic discoloration was present on the outer side of the cecum and about four or five inches above the ileocecal valve. The nail could be palpated at this site and its point was demonstrated, by manipulation, to be fixed in the wall of the cecum. The sharp end of the nail was backed out and moved with the aid of Lockwood forceps, head first, down the bowel lumen to the appendix vermiformis, into which it was "milked" point forward. Appendectomy was then performed and the nail with the appendix was removed. The accompanying illustration shows the nail as found in a fold of mucosa of the cecum at "A" and also as moved into the appendix vermiformis at "B" ready for re-

moval by appendectomy. Recovery was uneventful and the patient left the hospital April 17, eleven days after operation. The pathologist's report follows: "Specimen of appendix vermiformis, 0.9 by 7 cm. Serosa has tags of fibrous tissues attached, otherwise is without evidence of inflammatory change. A steel nail is present

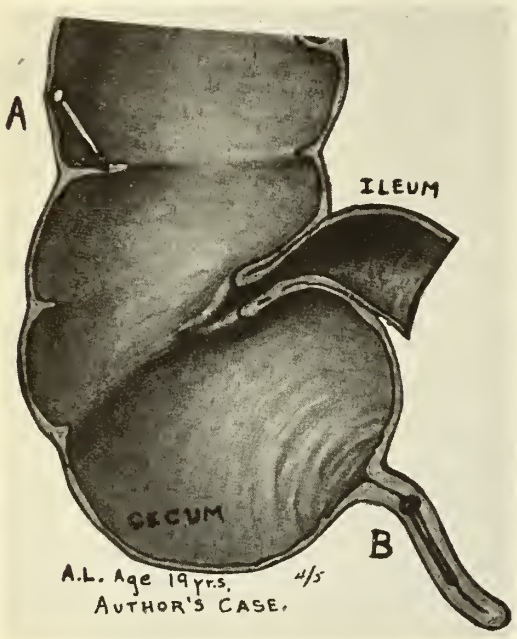

Fig. 1. Drawing shows the nail partially perforating the bowel wall at *A* and also in the lumen of the appendix vermiformis at *B* into which it was "milked" for removal by appendectomy.

in the lumen. Its surface is black but smooth. The nail is 3.5 cm. long, about 2 mm. in diameter and the head is 5 mm. in diameter.

Cases 2, 3, and 4.—These three boys (J. B., aged 12; A. S., aged 6, and T. F., aged 7) though seen months apart, had accidentally swallowed a steel ball from an automobile bearing, which had been used in playing marbles. All steel balls were about one-half inch in diameter. In each patient the steel ball remained in the caput coli and removal was accomplished without surgery. After thoroughly emptying the large bowel, the patient was placed upon the radioscopic table in the Trendelenburg position and, by shaking his body, the steel ball was made to roll to the hepatic flexure in the colon and from there through the transverse colon. All during this process, the progress of the foreign body was observed under the fluoroscope. When the patient stood up, gravity carried the metal ball to the anus, through which it was expelled.

TABULATION OF PREVIOUS CASE REPORTS

1. Several nails and pieces of glass removed from the stomach and ileum of a professional nail swallower. Stewart, J. C.: Jour. Am. Med. Assn. 48:2028, 1907.
2. A wooden splinter accidentally swallowed by a four year old boy removed from the ileum. Spence, T. B.: Long Island Med. Jour. 2:65, 1908.
3. A stiff hair bristle accidentally swallowed by a seventeen year old girl removed from the appendix. Spence, T. B.: Long Island Med. Jour., 2:65, 1908.
4. A wire paper clip taken with suicidal intent by a thirty-five year old insane woman removed from the ileum. Ross, G. G.: Ann. Surg., 63:247, 1916.
5. A piece of glass accidentally swallowed, perforated Meckel's diverticulum, producing an umbilical abscess in a five year old boy. Kilgore, F. H.: Med. Rec. and Ann., 17:125, 1923.
6. A wooden toothpick, accidentally swallowed, removed from the cecum of an adult. Ross, G. G.: New York Med. Jour., 86:880, 1907.
7. A steel nail, accidentally swallowed, removed from the duodenum of a twenty-three year old man. Mairane, M.: Adch. Ital. di Chir., 7:502, 1923.
8. A hairpin, swallowed with suicidal attempt, removed from the duodenum and gallbladder of a thirty-one year old prisoner. Arch. f. Klin. Chir., 128:437, 1924.
9. A pin, accidentally swallowed removed from the duodenum. McCartney, F. M.: Denver Med. Times, 27:359, 1907-08.
10. Several teaspoons removed from the stomach of a twenty-nine year old insane woman. Balfour, D. C.: Jour. Am. Med. Assn., 66:421, 1916.

URETERAL STONE WITH PERIURETERAL EXTRAVASATION

ARTHUR N. COLLINS, M.D., and GAGE CLEMENT, M.D.
Duluth, Minnesota

We have not been able to discover in the literature any recorded cases of non-traumatic ulceration or perforation of the ureter. Young and Waters* have shown two radiographs of extravasation of the pyelographic medium into the retroperitoneal space, but both of these cases are the result of puncture of the ureter by the ureteral catheter. The case which we report herein shows extravasation of the medium into the retroperitoneal space through an opening in the wall of the ureter caused by a sharp calculus.

The essential points in the history are as follows:

H. M., a male, aged 58, was seen by Dr. S. H. Boyer, and admitted to St. Luke's Hospital September 12, 1930, complaining of knife-like pain in the left side of the abdomen. His first attack came on three weeks preceding admission and lasted one and one-half hours. Since that time he had had difficulty in starting urination. He complained also of frequency and burning. These symptoms occurred only at night, although he was unable to tell at any time whether or not the bladder was completely empty. Eight days preceding admission he had a recurrence of the pain and it had continued intermittently ever since. There was no evidence of hematuria or cloudy urine.

Physical examination was essentially negative except

*Young and Waters: Urological Roentgenology, pages 357 and 363.

that the teeth were poor, showed pyorrhea and had many fillings. The left lower abdomen was rigid and tender, especially in the left iliac region. The left flank was tender and spastic. The lumbar muscles on the left side were prominent, spastic and very tender to deep percussion.

Fig. 1

Fig. 2

Fig. 3

On admission the temperature was 98.6, pulse 86, respiration 18. Urine showed a trace of albumin, an occasional leukocyte and many erythrocytes. The red blood cell count was 4,300,000 and the white count was 12,100. Blood urea was 18.9 mgs. and creatinin 1.8 mgs. Stereo-roentgenographs of the abdomen showed a small opaque area about 8 x 4 mm. situated in the path of the left ureter just opposite the upper border of the fourth lumbar body. It was diagnosed as probably a ureteral stone (Fig. 1).

On ureteral catheterization the pyelogram showed the same opacity lying just beside the catheter in the same relative position. Urine from the right kidney was clear and showed microscopically an occasional epithelial cell with one or two erythrocytes per high power field. Urine from the left kidney was clear and showed a few leukocytes with twenty-five to forty erythrocytes per high power field. The pyelogram (Fig. 2) showed no change in the position of the stone, negative calices, and negative kidney pelvis. There was some extravasation of the filling medium into the retroperitoneal space extending in a diffuse cloud from the kidney pelvis to the crest of the ilium. It seemed improbable that the kidney could be so large and still not show some deformity of the calices, especially in the lower pole. The arrangement of the shadows caused by the medium was such as is often seen in infiltration into soft tissue and not into one well defined cavity. The filling medium was withdrawn from the kidney pelvis immediately after the pyelogram was made. The film (Fig. 3) was taken fifteen minutes after Fig. 2, and showed the kidney pelvis practically empty.

At operation the stone (Fig. 4) was removed from the ureter. There was evidence of light, crisp adhesions from inflammation in the neighborhood of the left kidney and ureter. These adhesions were easily separated. The kidney was apparently normal. The ureter was slightly thickened and there was induration of the tissues around it. The stone was located in the ureter

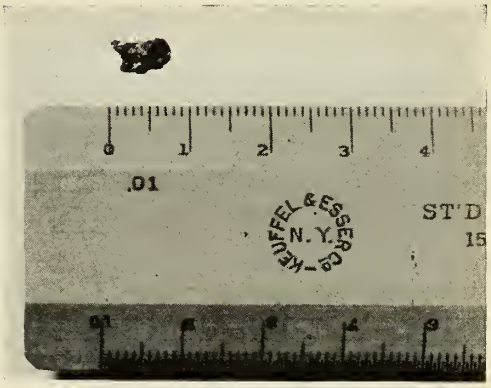

Fig. 4

about 7 cm. below the junction of the kidney pelvis and ureter. It was removed through a small incision in the ureter. The incision in the flank was closed with drainage.

SUMMARY

The pyelograms show the ureteral catheter in the kidney pelvis. The kidney pelvis was well filled with opaque medium, the catheter entered the ureter easily, the extravasation occurred around the ureter at the point where the stone was located. Suction through the catheter removed the filling medium from the kidney pelvis but not from around the ureter. The stone was not displaced by manipulation. It had a sharp point which could have penetrated the ureteral wall. The surrounding tissues at operation showed evidence of inflammation indicating an extravasation from the ureter.

President's Letter

IT IS frequently stated, especially by social writers and the press, that the medical code of ethics is outworn, obsolete and absurd. Leaving the reasons for so thinking out of consideration one is none the less moved to wonder just what is meant by the term medical ethics.

The terms ethics and morals are of very similar, if not precisely the same meaning. The former term derives from the Greek and means right conduct; the word morals is from the Latin and likewise means right conduct. Thus we may conclude that ethics concerns itself with the rightness and wrongness of things, decency as against indecency, the moralities and the immoralities. We must not confuse the social amenities, the conventions and mere etiquette, with ethics. These latter are but a polish, very pleasing to encounter and well calculated to grace social intercourse, but superficial withal. They may connote the cultured gentleman or but cloak the true character of a most unethical, immoral or unmoral scamp. Ethics is the product of character. Character determines conduct. Conduct may bespeak character but it does not make it.

No one of character needs to be told what constitutes honor and decency and fair dealing between individuals. Such a person knows these things instinctively. It is rather the broader aspects and applications of ethics that challenge our understanding. From time immemorial the ethical relation between physician and patient has been that of placing the patient's feelings, interests and physical welfare above everything else; an accepted rule of conduct that at times calls for no small degree of self abnegation, and when faithfully followed by physicians is found to eliminate personal differences between them and establish bonds of confidence and friendship. Such practice can never be obsolete nor absurd.

Our ethical relations to the public and our duty to ourselves are indeed puzzling at the present time, and this applies not alone to the medical profession but to practically all other callings. Social conditions are forever changing and that means adaptive ethical changes also. The latter sometimes lag but they will always come, just so long as fineness of character exists. Our critics might do well to note the difficulties existing in their own fields of endeavor before telling the medical profession how to correct theirs.

Advance in knowledge and industry has resulted in tremendous social changes accompanied by a general consciousness of the desirability of what is called social service. This is the point at which our ethical uncertainties begin. The whole-time clinical teaching in our medical schools, public health nursing, social service nursing, health centers, public health education, preventive medicine both lay and official, the free and the pay clinic, compulsory industrial insurance, actual curative and corrective medicine practiced by the state and a host of similar changes and allied movements have wholly changed the face of the practice of medicine. The changes compel adaptive changes in medical ethics.

How we shall meet these changes with moral integrity is our problem. No one man, no group of men, can at this time effect a solution out of hand. All through the variations of the present and the future the great thing that concerns us as doctors, and also the public, is the preservation of a united well organized profession, high ideals, a never failing opportunity for professional advancement, and of financial reward commensurate with the value of professional attainments and of services rendered.

The holiday season is at hand and your retiring president takes pleasure in offering your succeeding one every felicitation and such aid as he may desire; in hoping that we may gradually find our way out of the maze in which we find ourselves today; in extending to all the seasons greetings, a Merry Christmas and a Glad New Year.

S. H. Boyer

President,
Minnesota State Medical Association.

Vol. XIII December, 1930 No. 12

THE ANTI-VIVISECTION BILL

Again the subject of vivisection. For many years the anti-vivisectionists have been striving to prohibit vivisection by legislation. Some forty bills have been presented to Congress during this period but never until now have they been able to get a committee recommendation of a bill, the previous bills having died in committee. So vigorous and persistent have their efforts been that finally they have succeeded in obtaining recommendation by the committee of the house, of a bill to prohibit experimentation on dogs in the District of Columbia. The cleverness of limiting the proposed law to the use of the dog is an appeal to the emotional nature of man, for the dog has always been man's particular pet. It is obvious that the enactment of this proposed bill would serve as a powerful entering wedge for the extension of similar legislation throughout the states of the union.

The question of the advisability of such a law should be approached from a common sense viewpoint and emotionalism should not be given too much consideration.

Have experiments on dogs added anything to the alleviation of human suffering and to the prolongation of human life? If so, there should be considerable hesitation before prohibitive legislation is enacted. Experiments on dogs were responsible for two outstanding triumphs in the field of therapeutics in recent years. The development of insulin in the treatment of diabetes and the discovery of the value of liver and liver extracts in pernicious anemia were the result of work done chiefly on dogs. Both remedies have relieved the symptoms and have prolonged the lives of thousands of human beings afflicted with these diseases. The results in these two instances alone have added much to the justification of vivisection. Mention might be made of the work that is being done in the prevention of distemper in dogs which promises to be effective. How will any method be evolved to prevent this disease which has proven to be such a scourge to the canine species in particular, if all experimentation on dogs is prohibited?

That needless animal experimentation is performed is admitted. That needless cruelty to animals has at times accompanied animal experiments is also admitted only to be severely condemned. We have, however, the word of Dr. Carlson, the eminent physiologist of Chicago, who is posted on the facts in the case, that such instances amount to only a fraction of one per cent of all experiments conducted. Doctors are similar in certain respects to any other group of mortals and among them are numbered a few who are lacking in human compassion.

A grave responsibility rests in the hands of those who supervise animal experimentation in the medical schools and research laboratories.

Experiments should be limited to problems which offer some chance of adding to the sum total of scientific knowledge and then anesthesia should be used.

Needless legislation of the sort mentioned will only put more useless and senseless laws on the statute books. Such procedure is as illogical as amputating an arm to cure a sore finger and will greatly curtail research which is so urgently needed to discover new remedies for the many human ailments in the treatment of which our hands are at present tied.

The logical solution of the problem—and there is a certain problem involved—is regulation of vivisection. Individuals and scientific institutions might well be given permits before they are allowed to carry on animal experiments of any sort, not merely on dogs, and a certain supervision conducted by a branch of the national government.

If the anti-vivisectionists were logical—which they are not—they would direct some of their energy against hunters and trappers. Some of the methods of the latter are notoriously cruel. Certainly anti-vivisectionists should not wear furs and logically should be strict vegetarians. This group includes some well-meaning sentimentalists and not a few men and women of means. They have resorted to emotionalism and, we regret to state, even misrepresentation in fighting fanatically for their ends, which, if attained, will result in grievously curtailing medical progress.

The present bill known as the Zohlman Bill (House No. 7884; Senate No. 4497) will be submitted to Congress, which convenes the first of this month, and will probably not come to vote until about February 1. Physicians realize the importance of defeating such a proposal. Every effort should be made to inform our congressmen of the true facts in the case.

WOMEN'S STATE AUXILIARY

The Women's Auxiliary of the Minnesota State Medical Association was one of the first auxiliaries to be founded. The question of the advisability of starting an auxiliary in Minnesota was fully discussed previous to its organization and the step was taken with the approval of the State Medical Association.

While the members of an auxiliary have few common interests compared to those of a medical society, an active auxiliary can undertake certain well worth-while activities.

Perhaps one of the most important functions of a medical auxiliary is the entertainment of visiting women at the time of medical conventions. This applies, of course, to the units in the larger cities, and the entertainment of the visiting women at the recent International Assembly in Minneapolis is a case in point.

Fully as important a function is the opportunity an auxiliary has for disseminating facts about medicine through its contact with various women's organizations. We are inclined to shut our eyes to the importance of using every channel possible to counteract the vigorous and often malicious propaganda being foisted upon the public by anti-vivisectionists, anti-vaccinationists and similarly minded individuals. The false reasoning and illogical conclusions reached by certain well-meaning, but perhaps often fanatical individuals is certainly in opposition to sane medical progress and detrimental to the public welfare. Continuous, not spasmodic effort to inform the public through every possible agency must be made to counteract the various anti's who seem to be tireless in their energy.

Legislative activities are mentioned as one of the functions of an auxiliary. Lobbying is out of the sphere of women, but members of an auxiliary can be informed as to choice of legislators and can disseminate such information.

We approve the aims of the Women's Auxiliary of the State Medical Association which are enumerated in this issue of the journal, and we offer our assistance in every way possible to further their objectives and make the auxiliary column of interest to members of their organization.

HISTORY COMMITTEE

We have long since returned from our vacation and find our editor has used up the material we furnished him a year ago.

On February last we read in the papers that the Italian Consul in New York wanted a New York barber arrested because he looked and dressed like Mussolini, and the Duce didn't like it. That reminded us that a St. Paul physician was arrested in Switzerland in 1854 as it was supposed that he was Joseph Mazinni, the Italian patriot. He told the Swiss police he was an American physician, so to test him his inquisitors

asked him about yellow fever. When he told them he had never seen a case, they were doubly sure he was an impostor, "as is not yellow fever an American disease?" Of course, in those days to most Europeans America was all alike from Argentina to Quebec. At any rate, he got out of jail after ten days in a small cell on a bread and water diet.

We find these "old Docs" interesting men in many ways. Let Dr. H. M. Workman at Tracy know what medical men lived in your town in the early days and what you know about them.

J. M. A.

NEW AND NON-OFFICIAL REMEDIES

The following products have been accepted by the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in New and Non-official Remedies:

LEDERLE LABORATORIES, INC.

Diphtheria Toxoid

MALTINE COMPANY

Maltine with Cod Liver Oil and Iron Iodide

Amytal.—Isoamylethylbarbituric acid.—Amytal differs from barbital (diethylbarbituric acid) in that one of the ethyl groups of barbital is replaced by an isoamyl group. The actions and uses of Amytal resemble those of barbital. It is proposed as a sedative and hypnotic in the control of insomnia and as a preliminary to surgical anesthesia. Amytal is also supplied in tablets containing 1½ grains. Amytal can be used before local or general anesthesia safely only by those who have had much experience and are familiar with the literature concerning such use. Eli Lilly & Co., Indianapolis.

Pulvules Sodium Amytal, 3 Grains.—Gelatin capsules ("pulvules") each containing 0.2 Gm. (3 grains) of sodium amytal, the monosodium salt of isoamylethylbarbituric acid. The actions and uses of Pulvules Sodium Amytal, 3 grains, resemble those of barbital. The product is proposed as a sedative and hypnotic in the control of insomnia and as a preliminary to surgical anesthesia. Pulvules Sodium Amytal, 3 grains, can be used before local or general anesthesia safely only by those who have had much experience and are familiar with the literature concerning such use. The pulvules may be administered by mouth or rectally. Eli Lilly & Co., Indianapolis. (Jour. A. M. A., October 18, 1930, p. 1178.)

Ampules Emulsion Mesurol, 20 per cent, 1 c.c.—A suspension of mesurol (New and Non-official Remedies, 1930, p. 100) in sesame oil, each cubic centimeter of which contains mesurol equivalent to from 0.103 to 0.117 Gm. of bismuth. Winthrop Chemical Co., Inc., New York.

Tablets Theocin 1 1/2 grains.—Each tablet contains theocin (New and Non-official Remedies, 1930, p. 415), 1½ grains. Winthrop Chemical Co., Inc., New York.

Ampules Mercurochrome-H. W. & D., 1%, 10 c.c.—An aqueous 1 per cent solution of mercurochrome-220 soluble (New and Non-official Remedies, 1930, p. 271) stabilized with ammonium hydroxide; in 10 c.c. ampules. G. D. Searle & Co., Inc., Chicago.

Ampules Mercurochrome-H. W. & D., 1%, 20 c.c.—An aqueous 1 per cent solution of mercurochrome-220 soluble (New and Non-official Remedies, 1930, p. 271), stabilized with ammonium hydroxide; in 20 c.c. ampules. G. D. Searle & Co., Inc., Chicago. (Jour. A. M. A., August 2, 1930, p. 343.)

Diphtheria Toxoid-Cutter.—Diphtheria Toxoid-Cutter (New and Non-official Remedies, 1930, p. 485) is also marketed in packages of one 45 c.c. vial. Cutter Laboratory, Berkeley, Calif.

Synthetic Thyroxine.—It contains not less than 65 per cent of iodine. It has the actions and uses of thyroxin, U. S. P. (New and Non-official Remedies, 1930, p. 403). Synthetic thyroxine is supplied in the form of ampules containing 1.1 c.c. of solution containing 1 mg., and in the form of a solution, each c.c. containing 2 mg., and in tablets containing 1 mg. Hoffmann-La Roche, Inc., Nutley, N. J. (Jour. A. M. A., August 16, 1930, p. 485.)

Antimeningococcic Serum.—Antimeningococcic serum (New and Non-official Remedies, 1930, p. 350) marketed in packages of two 15 c.c. syringes with apparatus for intraspinal injection; in packages of one 50 c.c. double-ended vial with apparatus for intraspinal injection. National Drug Co., Philadelphia.

Mercurochrome Suppository-Aces. — Suppositories representing a 2 per cent solution of mercurochrome-220 soluble (New and Non-official Remedies, 1930, p. 271) in a slightly aromatized, hydroglycero-gelatin base; each suppository weighs approximately 6.5 Gm. (100 grains). Aces Laboratory, Inc., Brooklyn, N. Y. (Jour. A. M. A., August 23, 1930, p. 594.)

White's Cod Liver Oil Concentrate.—A cod liver oil concentrate in the form of tablets (wafers), each containing not less than 250 Vitamin A units and not less than 100 Vitamin D units. White's cod liver oil concentrate possesses properties similar to those of cod liver oil so far as these depend on the fat-soluble vitamin content of the latter. White Laboratories, Inc., Gloucester, Mass. (Jour. A. M. A., August 30, 1930, p. 663.)

FOODS

The following products have been accepted by the Committee on Foods of the Council on Pharmacy and Chemistry of the American Medical Association for inclusion in Accepted Foods:

Argo Corn Starch (Corn Products Refining Co., New York). A refined corn starch of high purity. It contains 86.95 per cent of starch. It yields 3.50 calories per Gm. (99.4 per ounce). Argo Corn Starch is proposed for use in puddings, custards, ice cream, a wide variety of desserts, in bakery products, and for thickening gravies, sauces, pie filling, stewed fruits, etc.

A PAGE FORUM OF THE COMMITTEE ON PUBLIC HEALTH EDUCATION

One of the cornerstones of lay security and trust in the medical profession lies in the fact that the doctor never refuses to come when and where he is needed.

Is it premature labor or the croup or a night of terror? The telephone will bring expert medical help yet—in Minnesota. Such reliance is one of the glories of medical practise earned by untold labor and hardship and not to be surrendered easily so long as the doctor wishes to remain what he has been, the trusted friend, and not the irresponsible hired employee.

But who knows what is to happen to this phase of the traditional practise of medicine if the dangerous state of affairs that exists these days in some of the large centers should spread? The profession in Minnesota has much to be thankful for that it is in Minnesota and not in Chicago or Detroit judging by an editorial appearing recently in the Wayne County (Detroit) bulletin on the subject of "Fake Calls and Badger Games."

The editorial follows:

The profession views with alarm the increase in fake calls made either for the purpose of the robbery or kidnapping of physicians, or the malicious application of the "badger game" to them.

Time was when the physician could go about his duties at any time of the day or night without giving a thought to the possibility of interference of any sort. The respect for his profession, and the personal sacrifices that are entailed in its practice seemed to render him immune as prey for the kidnaper, blackmailer or hold-up man. That time, unfortunately, is no more and it is now necessary to warn physicians repeatedly of the dangers attendant upon calling on those about whom they know nothing.

A few recent happenings will serve to illustrate some of these dangers. The first is the kidnaping of Dr. Frank L. McPhail of this city when he responded to the call of a supposed patient. Next is the "enraged husband" act reported from New York City, which is put over on doctors who have responded to the call of a "sick" woman alone in a hotel room where the irate husband rushes in as the doctor is about to make an examination; and finally there is the accusation of assault made by a female narcotic addict against the physician who refuses to administer morphine. All of these incidents and many more like them are serving to make physicians exceedingly wary and while no restraint has been or ever will be placed on the exercise of the doctor's judgment in deciding on whom to call or not to call, the time is rapidly approaching when the taking of chances will be reduced to a minimum by the men themselves.

It is regrettable that such a state of affairs exists for it works a hardship on those who have legitimate need for the services of a physician, yet nothing can be done about it since the risks involved make the refusal to call anywhere at any time thoroughly justifiable.

OF GENERAL INTEREST

Dr. L. T. Sussex of Rochester, Minnesota, is now located in Havre, Montana.

Dr. Edward Waldemar Anderson, formerly of the Mayo Clinic, Rochester, is now living in Hanover, New Hampshire.

Dr. E. E. Kidder has moved from Hibbing, where he was a member of the staff of Rood Hospital, to Stevens Point, Wisconsin.

Dr. Ralph Garfield Mills, formerly of Rochester, Minnesota, is now associated with the Wiley-Smith Clinic, Fond du Lac, Wisconsin.

Dr. Emil Geist, Minneapolis, returned on Friday, October 24, 1930, with Mrs. Geist, from Paris, where he has been attending the meeting of the International Orthopedic Society.

The publication of the November issue of MINNESOTA MEDICINE was considerably delayed on account of the moving of the printing plant from 2429 University Avenue to 2642 University Avenue, Saint Paul.

Dr. F. C. Rodda, Minneapolis, addressed the Scott-Carver County Medical Society at Montgomery, November 11, on Pediatrics. Dr. W. A. Fansler, also of Minneapolis, talked on Hemorrhoids. Dr. Thomas P. Martin of Arlington was elected to membership in the society.

J. A. Myers of Minneapolis addressed the following societies during the month of November: McLean County Medical Society in Bloomington, Illinois, on November 6, and Illinois Tuberculosis Association in Jacksonville, Illinois, on November 7; the Iowa Tuberculosis Association, the Iowa Pediatric Association, the Des Moines Academy of Medicine and the Polk County Medical Society, all of Des Moines, on November 14.

Following his return from Philadelphia, Pennsylvania, where he did two years' post-graduate work in surgery at the University of Pennsylvania Post Graduate Medical School, Dr. Brand O. Leopard has formed an association with Dr. W. B. Richards, whose practice is limited to pediatrics and obstetrics, and has opened offices with him at 306 Granite Exchange Building, Saint Cloud, Minnesota, for the practice of surgery and general medicine.

On October 6, 1930, at a dinner meeting of the Medical Assembly, a recently organized group of younger physicians in Saint Paul representing the specialties, the following officers for the year were installed: Gordon R. Kamman, president; Richard B. Hullsiek, vice president; James J. Swendson, secretary-treasurer. Drs. Joseph E. Borg and Richard B. Hullsiek addressed the society on "The Use of Potassium Sulphocyanate in Hypertension" and "Hematuria as a Symptom."

A banquet was tendered Dr. L. L. Sogge on November 14, 1930, in honor or his election to the presidency of the Minnesota State Medical Association. The banquet, graced by Dr. A. G. Chadbourn as toastmaster, was held at Memorial Hall, Fulda, Minnesota, and was attended by some seventy doctors and their wives. The dinner was served by members of the local auxiliary, and vocal and cello solos were given by Mrs. Engh and Mrs. Stratte. Dr. S. H. Boyer, retiring president of the association, spoke on "The Significance of State Medicine." Dr. H. M. Workman spoke on the work and personnel of the State Association and Dr. H. M. Johnson of Dawson explained some of this work being done by the association. Mr. F. M. Brist, attorney for the State Board of Medical Examiners, spoke on the Basic Science law and the recent suit which established its constitutionality. Dr. F. H. Aldrich of Belview rehearsed some of the activities of the Legislative Committee and greetings were brought from Iowa by Dr. Hoff of Sibley.

The 1930 Christmas Seal sale serves to call attention to certain important late developments in our knowledge of tuberculosis. The most interesting of these is probably our newer knowledge of the significance and character of childhood tuberculosis, upon which the campaign for the sale of Seals is laying particular stress this year.

Emphasis in the tuberculosis campaign now has turned to the detection of the childhood type of the disease. Such detection depends, in its turn, upon widespread, well directed public education as well as upon the doctor in his private practice.

It has always been the principal work of the Christmas Seal organization to carry on the education of the public in the latest methods of control of tuberculosis. It has carried on the campaigns of education by means of literature, lectures, newspapers, magazines, and demonstrations of needed activities, and in all these activities it has the hearty interest and cooperation of the medical profession in this state.

There is a unique coalition in Minnesota between the organized medical profession and the Christmas Seal organization. As a result, the health information broadcast under public health association auspices is medically supervised, authentic, proper, and designed to serve the best interests of both public and physician. This fruitful coöperation has provided important and valuable short courses in tuberculosis for the physician, the latest held recently at the state sanatorium at Ah-Gwah-Ching. These, too, were financed by Christmas Seal funds.

The Christmas Seal campaign deserves the wholehearted support of the medical profession and throughout the state physicians are taking an active part in both the fund raising and educational phases of the campaign.

Tuberculosis, despite the fact that the death rate for all age groups has been cut in half, still ranks first as a cause of death in that important age group from fifteen to forty-five years.

CONSULTATION BUREAU

WM. A. O'BRIEN, M.D., *Director*
Minnesota State Medical Association
11 West Summit Avenue
Saint Paul, Minnesota

1. *Question.*—I want to get your advice as to treatment in the following case: A married woman, age 30, whose past history is essentially negative, developed an acute bilateral iritis; about a week after this attack pain developed in the dorsum of her left foot. The pain was very severe but there was very little swelling. During the next three days the right knee joint became involved. This was soon followed by the left knee joint, and indefinite involvement of both wrist joints. It is now a little over three weeks since the foot became involved. The swelling of the joints has practically subsided but she is still having unbearable pains in her right knee and left foot. I have tried to immobilize the knee by putting the leg in a splint but was unsuccessful in relieving her pains except for a very short time. Salicylates were pushed with no apparent relief. Her iritis has shown some improvement with constant recurrences. Now the question arises whether I would be justified in using typhoid vaccine (foreign protein) intravenously. Should the vaccine be diluted before giving it by the intravenous route? What other form of treatment would be of benefit in this case?

Answer.—1. Atropine, one per cent, in each eye, sufficient to keep them properly dilated; smoked glasses to be worn in bright light, and intermittent hot packs. Sodium salicylate, available in ampules containing 15½ grains in solution, should be given intravenously, one ampule at intervals of five days until improvement sets in. If this does not bring about sufficiently speedy results, foreign proteins in the form of typhoid-paratyphoid a and b can be used intravenously, beginning with a dosage of ⅓ minim in 2 c.c. of sterile water. For this the patient is hospitalized for twenty-four hours and no breakfast allowed, the injection being made during the forenoon. The resultant chill and fever are treated symptomatically as required. The rise in temperature should be noted and subsequent dosages determined in accordance with the elevation. Subsequent dosages are usually ½ and ¾ minims at intervals of three to four days.

2. The case history suggests a Neisserian infection. The iritis, of course, should be treated with atropine solution strong enough to keep the pupil dilated. Hot bathing of the eye should also be done. I think it advisable to have a complement fixation test and if a Neisserian infection is present, to give a vaccine. The foreign protein typhoid given intramuscularly or subcutaneously would probably be of benefit through the reaction following, and the high fever. The history would indicate a general type of infection rather than an infection due to infected teeth or tonsils or syphilis.

2. *Question.*—I have under my care a young man 22 years of age who has a chronic gonorrheal anterior urethritis. There is no burning on urination and no frequency, but there is a persistent morning discharge if the patient milks out the urethra, and likewise there is a persistent shreddy first glass with clear second and third glasses. Prostatic massage does not yield any discharge. There are no symptoms of prostatic involvement. The treatment I have been using is irrigations with 1–5,000 potassium permanganate solution followed by injection of 5% neosilvol and pyridium, two 0.1 gram tablets t.i.d. The results of this treatment after two months are still unsatisfactory. Can you suggest any further therapy?

Answer.—The history and reported findings support the diagnosis "chronic urethritis." That the process is confined entirely to the anterior urethra is not so certain. Effective prostatic massages will always yield secretion which can be milked out to the meatus and collected for microscopic examination. A number of massages may be required before the material is finally forced through occluded ducts. To avoid misinterpretation as to the source of the contents of the secretion, the prostatic massage and collection of secretion should be carried out only after exudate in the urethra has been flushed out by voiding or by a urethral irrigation. Pus cells in the secretion indicate an inflammatory process in the prostate. This requires treatment by Kollman dilations, prostatic massages and antero-posterior irrigations. Hot rectal irrigations are also useful in the acute stages. In only a limited number of cases will the treatment thus far employed be effective in completely clearing up infection confined to the anterior urethra. Infected periurethral glands (littritis), surface granulations and mural infiltrations occur in a large proportion of cases and would explain the findings reported. These conditions are effectively treated by massages of the urethra over sounds, the passage of sounds of increasing size up to F 30 and by anterior injections of 2% mercurochrome.

3. *Question.*—The following case has stubbornly resisted treatment since coming under my observation: Male, age 40, married, the father of two children aged four and two, living and well. He is a farmer, well built and well nourished, and strong. No history of any illness until three years ago when he was laid up over three months with acute articular rheumatism. Since then he has had occasional pain in the joints once in a while, but not sufficient to need attention. Last week while haying he got something into his right eye. It was very sore and red. Two weeks later when he came to my office I found a marginal ulcer of the right cornea in addition to the general redness and inflammation. Tonsils were enlarged and crypts filled with whitish and yellow matter. Teeth pyorrheic. Advised *x*-ray and report from the dentist stated no sign of abscess. Tonsils removed under general anethesia two weeks ago. Good recovery. Urinalysis normal. Blood pressure 169/90. Have been giving him autocondensation at the office every other day the past week or two. Locally warm, wet applications, atropine, novocaine with adrenalin ointment, alternated with butyn and metaphen ointment. Also local eye wash of boric acid with zinc sulphate and aqua camphor. Internally he has been getting protonuclein tablets, now discontinued. Now getting KI, grains X, t.i.d. pc. Also cinchophen, grains V, t.i.d. Anything you

GETTING INTO PRINT: AN EXHIBIT FOR MEDICAL WRITERS*

It seems desirable that investigators who are producing material for publication should know of the attention that all they write requires. Information of this sort might result in shorter papers, elimination of non-essential illustrations, and fewer corrections in proof.

*From the Division of Publications, The Mayo Clinic, Rochester, Minnesota.

For the annual intramural exhibit at The Mayo Clinic, a replica of an open book, represented in the accompanying photograph, was constructed of wood and wall board. The book was 6 feet tall and 8 feet wide over all. Forty-two pictures were drawn or adapted to illustrate consecutive essential steps in getting an article into print. These pictures were pasted on the surfaces that represented opposing open pages of the book. The book stood against a wall on a shelf placed 20 inches above the floor, and occupied 22 inches of horizontal space.

RICHARD M. HEWITT, M.D.

The replica of the open book. Because of reduction, the numerals and legends of the drawings are difficult to read. They are as follows: 1. Author preparing his paper. 2. Author dictating. 3. Author's secretary typing. 4. First editor in editorial department of clinic. 5. Second editor in editorial department of clinic. 6. Typist in editorial department of clinic. 7. Manuscript proof readers in editorial department. 8. Making corrections on manuscript in editorial department. 9. Author reading final manuscript. 10. Inserting author's corrections in editorial department. 11. Manuscript off to publisher. 12. First editor in publishing house. 13. Second editor in publishing house. 14. Copy editor in publishing house. 15. Foreman of composing room. 16. Linotype operator setting article. 17. Boy making galley proof. 18. Proof readers in publishing house. 19. Linotype operator setting corrections. 20. Printer inserting corrected lines. 21. Boy making second galley proof. 22. Verifying corrections on galley proof. 23. Author's proof back to editorial department of clinic. 24. Examining author's proof in editorial department of clinic. 25. Author examining galley proof. 26. Examining author's changes in editorial department of clinic. 27. Author's proof off to publisher. 28. Editor in publishing house examining author's corrections. 29. Linotype operator setting author's corrections. 30. Printer inserting corrected lines. 31. Make-up man making pages. 32. Boy making page proof. 33. Editor in publishing house examining page proof. 34. Editor-in-chief in publishing house examining page proof. 35. Linotype operator setting corrections. 36. Make-up man inserting corrected lines. 37. Stereotyper. 38. To press. 39. Binder. 40. Mailers. 41. The issue of the journal on its way. 42. Author reading his article.

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

STATE OF MINNESOTA *vs.* MASON

On November 12, 1930, the above defendant, Elmer Mason, entered a plea of guilty of practicing healing without a Basic Science certificate before the Honorable Judge Gates at Winona, Minnesota.

Mason was the ringleader of a group of Indian doctors who, during July and August, sold between four and five thousand dollars' worth of Indian roots and herbs to the citizens of Fillmore and Houston Counties.

Another member of the group has completed a sixty day sentence in the county jail of Houston County.

Judge Gates, after hearing the facts in the case, sentenced Mason to serve three months at hard labor in Houston County. This sentence means that Mason will be put to work in the rock quarry where Houston County obtains the material for its roads. Sentence like this will go a long way toward preventing any return of quacks in that part of the state.

Judge Gates is to be commended for his firmness in the disposition of this matter.

Mr. Brist representing the State Board of Medical Examiners reports the finest of coöperation from Mr. Flynn, the County Attorney, and Sheriff Brown.

HOSPITAL CHART OWNERSHIP

The following letter written by Mr. F. M. Brist, attorney for the Minnesota State Board of Medical Examiners, contains legal opinion in answer to several questions which are likely to occur to physicians and hospital authorities and therefore merit publication:

September 15, 1930.

J. P. McDowell, M.D.,
St. Cloud, Minn.

Dear Dr. McDowell:

In answer to your two previous written inquiries concerning the ownership of a hospital chart and certain other questions concerning the rights and liabilities of the hospital in connection therewith I set out below your questions, the answers thereto and my reason for the same:

Q. 1. To whom does a hospital chart belong?

A. To the hospital.

Q. 2. May a patient demand his chart, read it or take it with him?

A. Any patient may demand his chart, that is, he may demand to read it or take it with him, but it is my opinion that his demand does not need to be complied with. As a matter of general policy I would advise that a patient while a patient of a hospital be permitted to see his chart if he so requests but under no circumstances would I permit him to take the chart with him.

Q. 3. If a Court's order is obtained, then is the chart to be turned over to someone outside the hospital or does a hospital representative take the chart to the court room and keep it in her or his possession and take it back to the hospital when the Court has finished with it?

A. If a subpena duces tecum is served upon the superintendent of a hospital, that subpena requires the appearance of the person named in the subpena, usually the superintendent, in Court at a specified time, together with the records described in the subpena. Therefore the chart under no circumstances should be turned over to someone outside the hospital. The hospital representative takes the chart or other record to the court room and keeps it in his or her possession and takes it back to the hospital unless the original record or chart is introduced as an exhibit in the case, in which event the courts usually allow a motion to withdraw the exhibit from the evidence or order its return after the case has been submitted to either the court or jury as the case may be. There are cases where the original exhibit, such as the chart or other records, is not introduced in evidence but upon agreement of counsel the items appearing upon the record or chart are read into the record as part of the evidence after the chart or record has been sufficiently identified to show that it is an authentic record.

Q. 4. May a patient, doctor or anyone else demand a hospital chart and hope to get it without a court order?

A. As previously stated, anyone may demand the chart, but in my opinion it does not need to be surrendered to anyone except as stated above where a subpena duces tecum has been served on the hospital.

Q. 5. May a patient or representative of a patient demand a copy of a chart?

A. The patient or representative may demand a copy of the chart but it is my opinion that such a demand need not be complied with. If such a demand is made the demand itself should be sufficient to put the hospital on an inquiry as to the reason for the demand being made. It is a matter of common knowledge that patients do not demand the hospital chart nor a copy of the same except under unusual circumstances, that is, unless there be an action pending in court either against the hospital, the attending physician, or both, or in cases involving an action under an insurance policy.

Q. 6. Has a second doctor with or without the consent of the patient the right to demand the chart kept of this patient by another doctor at some previous time?

A. Doctor number 2 has a right to make the demand but it is my opinion that the hospital is under no obligation to exhibit or turn over to the second doctor a chart made during the treatment of the patient by a previous doctor. I call your attention to the fact that your question number 6 states that the chart was made by another doctor. I am answering all of your questions on the theory and on the assumption that no chart is made by the attending physician but rather that the chart is made by someone in the employ of the hospital.

The last question in your first letter, "Just whose property is the hospital chart?" This is answered in question 1.

I have very carefully considered the questions personally and I find that we have no statutory law in Minnesota on the subject of the ownership of a hospital chart. In other words there is no statute in Min-

nesota that compels a doctor or a hospital to keep a hospital chart. Section 5362, Mason's Minn. Statutes for 1927, makes it mandatory that "all superintendents, managers or persons in charge of lying-in or other hospitals, almshouses, charitable or other institutions, public or private, to which persons resort for confinement, treatment of disease, care, or are committed by process of law, shall, at once, make and preserve a record of all the personal and statistical particulars relative to the inmates now in, or hereafter admitted to their institutions, that are required to be stated in the certificate of birth and death provided for by this act and on or before the tenth of each month shall file with the state board of health, on a blank provided by such board for the purpose, a report of all births and deaths, or still-births, occurring in such institution during the previous month. If admitted for medical treatment of disease the physician in charge shall specify, in the record, the nature of the disease and where it was contracted."

However, you will note that the information there required to be kept is only that information that is required to be stated in the certificate of birth and death.

Section 4314, Mason's Minn. Statutes for 1927, provides that the records kept by a hospital of the medical or surgical treatment given to an employee in such hospital shall be admissible as evidence of the medical and surgical matters stated therein, but shall not be conclusive proof of such matters.

Section 4314 above quoted applies only to cases coming under the Workmen's Compensation Act. The section quoted is not in the chapter on Witnesses and Evidence. It is to be found only in the chapter entitled Workmen's Compensation Act and is applicable only thereto.

I call your attention to Sec. 9814, Mason's Minn. Statutes for 1927, which provides that every person with sufficient understanding may testify in any action or proceeding, civil or criminal, in Court or before any person who has authority to receive evidence, except as follows:

Sub. 4. A licensed physician or surgeon shall not, without the consent of his patient, be allowed to disclose any information or any opinion based thereon which he acquired in attending the patient in a professional capacity and which was necessary to enable him to act in that capacity.

The question of the ownership of a hospital chart has never been before a court of final resort in this state or a court of last resort in any state in so far as we have been able to ascertain. This makes it necessary for one to go into the history of a chart and the relationship existing between the patient and the hospital.

In the first place the relationship existing between the hospital and patient is a contractual one, the hospital agreeing to furnish certain facilities and certain care while the patient is an inmate of the hospital for reasonable compensation, which compensation may or may not be agreed upon in any definite amount at the time of the admittance of the patient to the hospital. As previously stated there is no statutory obligation on the part of a hospital to keep a chart. The patient comes to a hospital to be cared for while under the treatment of either a private physician or in some cases treatment of a physician in the employ of the hospital. Hospital charts are kept so that the attending physician and those in charge of the hospital may have a better knowledge of the trend of the patient's case from day to day and have knowledge of certain medicinal administrations and other things done for the patient. There no doubt was a time when hospital charts were not kept just as there was a time when fractures were set without x-ray pictures being taken. We did not always have available the x-ray and no doubt there is work done today without the aid of the x-ray. Take a concrete case for example. A patient goes to a hospital to be operated upon for the removal of gallstones; an x-ray picture is undoubtedly taken to confirm the diagnosis. The surgeon performs the operation, removes the gall stones; the hospital through its employees ministers to the necessities of the patient. The patient pays for this service, however. The patient did not come to the hospital to buy x-ray pictures nor to buy hospital charts. It is true that the cost of rendering that service is included in the patient's bill. The patient did come to the hospital for the treatment and removal, if necessary, of the gallstones. If that service is rendered and the gallstones are removed, whether the patient recovers or not the service that the patient contracted for has been rendered. There is no liability on the part of the doctor nor the hospital if the patient should not recover unless there has been negligence on the part of either the hospital or the attending physician. Such negligence, before liability can be established, must be the approximate cause of the death of that patient.

Another vital reason for the keeping of hospital charts is for the protection of the hospital as well as the attending physician. Patients sometimes do become dissatisfied with the treatment previously given because they develop some further disorder, or perhaps for a recurrence of their former ailment they may prefer to consult another doctor who may or may not criticise the treatment described by the patient as having been previously given. This is one reason why hospitals should maintain a chart and a complete record of the case from start to finish, such record to be the absolute property of the hospital and to be preserved for a length of time at least equivalent to the statute of limitations relating to malpractice suits, and in my opinion for a considerable longer period. I can see no reason based on any sound theory why the second doctor in a particular case should feel that he has an absolute right to even see the chart prepared by the hospital in former treatment of that patient. I would advise, as a matter of business, unless there is some good objection to the contrary, that such a courtesy be extended to the doctors who subsequently treat a patient and in no event should hospital charts be kept where they can be removed or copied, as you mention in your letter of September 5th. If the patient has a meritorious action pending in court and the patient desires the hospital chart he has available a proper manner in which to obtain the same.

Under no circumstances should a hospital at any time be in the position of not having a record of the patient, as you state in your letter. Before a hospital chart is taken to court a copy should be made of that chart and retained by the hospital. There is no reason why any expense incident to the furnishing of a copy of the chart should not be borne by the party requesting the same.

Our Supreme Court has held in the case of Price vs. Standard Life and Accident Insurance Co., 90 Minn. 264, that the entries made by the superintendent in charge of a hospital could not be introduced in evidence because they constitute hearsay testimony and furthermore violated the statute prohibiting the examination by a physician as to certain matters without the consent of his patient.

This matter was before the Supreme Court of Michigan in a case wherein the Mass. Mutual Life Ins. Co. brought a mandamus action against the Board of Trustees of the Michigan Asylum for the Insane to compel the Board of Trustees to permit the insurance company to inspect the records of the asylum. The purpose being to obtain information concerning the mental and physical condition of a patient. Their action was based on the theory that the records of an insane asylum are public records and that at common law public records could be inspected. The Supreme Court of Michigan denied the writ of mandamus and cited the Price case above quoted. The Court held that the information contained in the records was strictly confidential and obtained while the relationship of patient and physician existed.

There is no question but what if the patient desires the matters shown in the record or chart to be aired in court it can be done by simply subpenaing the doctor and the person in charge of the records in the hospital. I would suggest, however, that when the hospital prints its forms for the keeping of these records and charts, a statement be printed upon the face of each one to the effect that the records or the chart, such as the case may be, are the property of the hospital and are not to be altered, copied or removed without the consent of the hospital. I also think that there should be some improvement in the manner in which charts are kept around a hospital. It should be made a very difficult matter for anyone to copy or remove the chart without the consent of the hospital.

It will be seen from the foregoing that the rights of all the parties concerned in this question depend first of all upon the ownership of the chart. It is my opinion for the reasons heretofore stated that the chart belongs to the hospital. As a matter of policy I believe that when requested patients, while patients of the hospital, should be permitted to examine their chart. If such a policy were established it would be conducive to the orderly keeping of the charts and it would lead to the hospital making every effort to keep a correct chart and one that could be proudly and successfully exhibited in Court. I trust that the foregoing will assist in clarifying the situation for you people.

Very truly yours,
(Signed) F. M. Brist.

FELLOWSHIPS FOR TRAINING IN EXTRAMURAL PSYCHIATRY

The following announcement is made by the National Committee for mental hygiene:

Minimum Requirements for Applicants—

These fellowships are designed to provide special training for physicians who have had previous hospital training in psychiatry but who wish to prepare themselves for extramural work in the fields of child guidance, delinquency, education, dependency, and industry.

Fellowships are open to physicians who are:

1. Under thirty-five years of age,
2. Graduates of Class A medical schools, and
3. Who have had at least one year of training in a hospital for mental disease maintaining satisfactory standards of clinical work and instruction. A longer period of hospital training is desirable.

Applicants able to meet these requirements will not be required to take competitive or oral examinations. Selections will be made on the basis of length and type of previous training in formal psychiatry, on general fitness for the work contemplated, and (in most cases) on the results of a personal interview.

General Details of Fellowships—

1. These fellowships cover a period of training approximately one year in length.
2. During this training period trainees usually are assigned for three to four months' periods at such places as the Boston Psychopathic Hospital; Judge Baker Foundation, Boston; Institute for Juvenile Research, Chicago, and other places of a similar nature, as well as to various child guidance clinics located in Cleveland, Philadelphia and other cities. Assignments to these training centers are not definite, however, and assignment to any given place will depend upon the availability of instruction at such place, as well as the special needs of the individual trainee. Assignments are not made for more than three months in advance, and adherence for the year's training period to a fixed program in advance is impossible.
3. These fellowships carry stipends at the rate of $2,000 to $2.500 for the twelve months' period.
4. Applications need not be filed within stated periods but will be received at any time. In the case of successful applicants, arrangements will be made to begin work whenever mutually convenient to the applicant and to the director of the training center to which the applicant is first assigned.

Applications or inquiries for further information should be sent to Dr. Frankwood E. Williams, Medical Director, National Committee for Mental Hygiene, 370 Seventh Avenue, New York, N. Y.

Plant's Magnesia Wafers.—Wafers, each containing magnesium hydroxide 0.3 Gm. (4.64 grains) compressed with the addition of sucrose and starch and essential oils as flavors. Used as an alkaline laxative and antacid. The magnesium content of each wafer is approximately equivalent to that of 4 c.c. of magnesia magma U. S. P. Plant Products Co., Cleveland, Ohio. (Jour. A. M. A., September 27, 1930, p. 935.

REPORTS AND ANNOUNCEMENTS OF SOCIETIES

MEDICAL BROADCAST FOR THE MONTH

The Minnesota State Medical Association
Morning Health Service

The Minnesota State Medical Association broadcasts weekly at 11:15 o'clock every Wednesday morning over Station WCCO, Minneapolis and St. Paul (810 kilocycles or 370.2 meters).

Speaker: William A. O'Brien, M.D., Associate Professor of Pathology and Preventive Medicine, Medical School, University of Minnesota.

The program for the month of December will be as follows:

December 3—Gall Stones.
December 10—Mental Hygiene.
December 17—Christmas Seal.
December 24—Aseptic Surgery.
December 31—Cancer of the Skin.

MINNESOTA STATE MEDICAL ASSOCIATION

The 1931 annual meeting of the Minnesota State Medical Association will be held in Minneapolis at the Nicollet Hotel, May 3, 4 and 5.

This meeting will be the 78th annual gathering of the association dating from 1853, the new date for the founding of the original society accepted by the House of Delegates at the suggestion of the Historical Committee at the last annual session in Duluth.

Plans for a large and important meeting are already being formulated. Resources of the University medical school and hospital will be utilized to the fullest to make it a scientifically memorable meeting.

MINNESOTA RADIOLOGICAL SOCIETY

At a meeting of the Minnesota Radiological Society held at the University Hospital, Minneapolis, Minnesota, on October 25, 1930, the following program was presented:

Roentgen Studies on the Onset of Lobar Pneumonia: Walter H. Ude, M.D., Minneapolis. Discussed by George E. Fahr, M.D., Minneapolis.

Childhood Tuberculosis: Malcolm B. Hanson, M.D., Minneapolis. Discussed by Jay A. Myers, M.D., Minneapolis.

Lympho-Epithelioma: A. U. Desjardins, M.D., Rochester.

Air Injection in the Diagnosis of Lesions of the Colon: Harry M. Weber, M.D., Rochester.

Roentgen Therapy in Carcinomatous Metastases to Bone: K. W. Stenstrom, Ph.D., and L. G. Erickson, M.D.

An informal dinner was held at the Town and Country Club, Dr. W. A. O'Brien acting as toastmaster. The Society was honored by the presence of two distinguished guests, Dr. James M. Martin of Dallas, Texas, and Dr. Bernard H. Nichols of Cleveland, Ohio. The following papers were presented:

Significance of Small Intestinal Gas in the Diagnosis of Bowel Obstruction: Edward Schons, M.D., St. Paul.

Clinical and Experimental Studies on Intestinal Obstruction: Owen H. Wangensteen, M.D., Minneapolis.

Intravenous Urography: Bernard H. Nichols, M.D., Cleveland, Ohio.

At the business meeting new officers were elected for the coming year as follows: Dr. B. H. Kirklin of Rochester, president; Dr. Gage Clement of Duluth, vice president, and Dr. Leo G. Rigler of Minneapolis, secretary-treasurer.

The time and place of the next meeting will be decided by the Executive Committee at an early date.

Leo G. Rigler, *Secretary.*

WOMEN'S AUXILIARY
Minnesota State Medical Association

Officers

Mrs. S. S. Hesselgrave	President	St. Paul
Mrs. James Blake	President-Elect	Hopkins
Mrs. Roy Andrews	First Vice President	Mankato
Mrs. F. J. Elias	Second Vice President	Duluth
Mrs. C. S. Sutton	Third Vice President	St. Cloud
Mrs. E. S. Boleyn	Recording Secretary	Stillwater
Mrs. Edward Schons	Corres. Secretary	St. Paul
Mrs. A. W. Coventry	Treasurer	Duluth
Mrs. John Catlin	Auditor	Buffalo

Committee Chairmen

Mrs. James Blake	Organization	Hopkins
Mrs. Hugh J. Tunstead	Legislative	Minneapolis
Mrs. Ben F. Davis	Public Relations	Duluth
Mrs. A. A. Passer	Editor	Olivia
Mrs. Carl Larsen	Finance and Budget	St. Paul
Mrs. E. A. Meyerding	Press and Publicity	St. Paul
Mrs. C. C. Chatterton	Social and Program	St. Paul
Mrs. J. R. Peterson	Social and Program	Minneapolis
Mrs. W. J. Byrnes	Parliamentarian	Minneapolis

Presidents of County Auxiliaries

Red River Valley	Mrs. H. Froelich	Thief River Falls
Rice County	Mrs. A. M. Hanson	Faribault
Stearns-Benton	Mrs. Warner Hemstedt	St. Cloud
St. Louis County	Brs. F. N. Knapp	Duluth
Washington County	Mrs. J. W. Stuhr	Stillwater
West Central	Mrs. C.F. Ewing	Wheaton
Wright County	Mrs. John Catlin	Buffalo

The tentative plans of the Women's State Auxiliary include:

1. The organization of twenty-three auxiliary societies (thirteen now organized).

2. Legislative Committee activity at the call of the Legislative Committee chairman of the State Medical Association when needed during the session of the legislature, a legislative chairman to be appointed in each county.

3. Health education through parent-teacher associations and other clubs by means of medical literature and lectures. The placing of health journals in schools and libraries.

4. The establishment of loans for medical students and nurses. Several county auxiliaries have made loans to student nurses, an activity recommended by both state and national auxiliaries.

5. Assisting county health units in Christmas seal sales.

6. Increasing the present membership of 838. Minnesota now ranks third among the state auxiliaries.

Mrs. S. S. Hesselgrave, Saint Paul, president of the Women's Auxiliary of Minnesota, and Mrs. James Blake, Hopkins, second vice president of the National Auxiliary, attended the executive board meeting of the National Auxiliary in Chicago, Friday, November 14, 1930.

Mrs. James Blake, president-elect, and former editor of the State Auxiliary, has turned over her work to Mrs. A. A. Passer of Olivia, who with the able coöperation of Mrs. E. A. Meyerding of Saint Paul, chairman of Press and Publicity, will have supervision of the Auxiliary column in MINNESOTA MEDICINE. The assistance of all local county auxiliary editors in sending in clippings of social and other activities of the auxiliary societies is requested.

HENNEPIN COUNTY AUXILIARY NEWS

The members of the Auxiliary of the Hennepin County Medical Society were hostesses to the visiting wives and daughters of the physicians attending the International Medical Assembly the week of October 20th to 24th. Mrs. Stephen Baxter was the general chairman for the entire week, with a group women assisting for the various activities. Mrs. Martin Nordland had charge of registering the guests. She reports 311 women (not including Minneapolis and St. Paul) given badges from her desk. These women were from thirty-two states and eight different locations in Canada.

Many social affairs—teas, luncheons, dinners and drives were planned for the visitors and were much enjoyed by guests as well as hostesses. The Ramsey County Auxiliary gave a musical tea and drive in compliment to the guests of the Hennepin County Auxiliary which was one of the outstanding features of the week. A rest room and lounge furnished by one of the Minneapolis stores at the Auditorium served as a rendezvous for both doctors and their wives. The Hennepin County Medical Library rooms were turned over to the women for the week, and were used for much informal entertainment all during the Assembly, including a tea on Tuesday and a bridge party on Friday.

This is the first time in the history of the International Assembly that an Auxiliary has taken over and entertained the ladies attending the meeting. The innovation proved a success, so much so, that the doctors in charge of the program decided to adopt the idea as a regular feature, and the Auxiliary in Milwaukee next year will be approached to do the same stunt, and the Hennepin County women wish them "good luck."

(MRS. JAMES) AGNES BLAKE.

PROCEEDINGS OF THE MINNEAPOLIS SURGICAL SOCIETY

Meeting of October 2, 1930

The regular monthly scientific meeting of the Minneapolis Surgical Society was held in the lounge of the Hennepin County Medical Society in the Medical Arts Building on Thursday evening, October 2, 1930, at 8 o'clock, Dr. A. T. Mann, President, presiding.

The meeting was called to order by the President, Dr. A. T. Mann. There were 21 members and 2 visitors present.

Minutes of the May meeting were read and approved. The Committee on revision of the Constitution and By-laws reported the changes which had been made, and a motion was carried that these be approved as read.

The scientific program consisted of two case reports and a thesis.

Dr. O. W. YOERG reported a case of Actinomycosis of the Abdomen.

The patient is a woman 44 years of age. Her past history is negative. She is the mother of four children, the youngest eight and the oldest fourteen. Her history was negative until February, 1928, when she was taken with what appeared to be an attack of acute appendicitis. An abscess was found, the appendix was removed and drainage instituted. She had a normal convalescence. The wound healed within four or five weeks and remained healed. She went back to her home on a farm and continued well for almost two years. She then went to her home doctor complaining of pain and a swelling in the right abdominal wall to the left and a little above the old appendix scar. The doctor watched her for a few weeks and then opened the indurated swelling and found a thin serous pus. That was in December, 1929.

In January, 1930, Dr. Yoerg saw her and his first impression was that a piece of gauze or something had been left in the abdomen at the time of operation. Under local anesthesia he opened the abdominal wall widely and found a number of sinuses and abscess cavities. Sections were taken and Dr. Smith, pathologist at Northwestern Hospital, reported nothing more than inflammation of a chronic type. The condition improved and finally healed. Two months later the patient developed a mass on the left side of the abdomen. This was hard and as it became larger her doctor opened it and found several abscesses on the abdominal wall. In April, 1930, Dr. Yoerg again opened the abdominal wall on the left side, this time under general anesthesia, and found sinus after sinus. Several sections and also some pus were taken at this time, and again the report came back from the laboratory that it was inflammatory. Dr. Yoerg stated that the diagnosis uppermost in his mind was a foreign body; it did not appear to be tuberculosis. He wished to state, however, that he had thought of actinomycosis and had looked for the granules but had found none.

In June, 1930, the patient returned to Northwestern

Hospital. She was anemic and complained of pain in the right leg. There were numerous sinuses over the abdominal wall. Gastrointestinal *x*-rays made at this time were negative. The leukocyte count was about 10,000; temperature ranged from 99.5° to 102° and 103°. A number of men saw her, among them Dr. Bulkley, who confirmed Dr. Yoerg's diagnosis of a foreign body. The abdomen was again opened and an abscess was found. Inside this abscess cavity was a mass which shelled out very readily; this mass appeared to be ovary, but on opening was found to be infiltrated with pus. This specimen was sent to the laboratory. Unfortunately a fecal fistula formed after this operation. On account of Dr. Smith's absence, the specimen was sent to Dr. Drake at the Swedish Hospital. About a week later Dr. Drake reported to Dr. Yoerg that he had found the ray fungus in the specimen. Since then Dr. Yoerg had also found a granule, the only one he had been able to find so far in the case.

The woman is still in the hospital and has considerable edema in the right leg although the pain has been less. Her hemoglobin is down to about 30 per cent. She was put on potassium iodid but did not tolerate it. This was discontinued and she was put on Lugol's, which she tolerates very well. In addition to this medication, Dr. Allison has given her four doses of deep *x*-ray therapy. The fecal fistula closed in about three weeks and since then the patient has apparently been holding her own. Dr. Yoerg said, however, that yesterday he could feel a mass just above the bladder.

Dr. Yoerg stated that his reason for reporting the case was that abdominal actinomycosis is rare, especially in women. The best information he could find was in an article by Sanford of Rochester, who had collected reports from various hospitals and Boards of Health and had found 690 cases reported in the United States up to 1926. Out of this number 80 per cent were in men. And only about 18 to 20 per cent of all actinomycosis is abdominal.

DISCUSSION

Dr. Willard White asked Dr. Yoerg if he had used copper sulphate in this case.

Dr. Yoerg stated that Bevan, in Chicago, was the first man to use copper sulphate extensively, but some men seem to think it does not change the results. He also stated that actinomycosis rarely follows the lymphatics; it goes by extension and may invade the veins; but whether or not the lymphatics are entirely free, he did not know. It does follow along tissue contiguous to the lymphatic.

Dr. E. K. Green asked Dr. Yoerg's opinion as to the portal of entry.

Dr. Yoerg replied that this is open to question. Some authorities claim that it is not transmitted from cattle to man; whether it is or is not, is a moot question. It is found in some grains and grasses and it is thought that people pick up and chew the grasses and the disease enters the system in that way. The usual case, of course, is "lumpy jaw." Most of the abdominal cases which Dr. Yoerg had found reported gave a history of having had an operation for appendicitis. In his own case just reported, Dr. Yoerg said there is a question in his mind as to whether the condition was there at the time of the appendicitis operation, since the patient had recovered and had remained well for almost two years.

Dr. O. H. Wangensteen stated that they had had two cases of abdominal actinomycosis at the University Hospital. A lethal outcome obtained in both instances and he understood that to be the usual occurrence in most instances of abdominal actinomycosis. The usual origin of the abdominal type is in the cecum; infrequently, however, as Bruce of Toronto has pointed out, the disease in the cecum itself heals, leaving no vestige of its previous existence there, but an induration of the abdominal wall and sinuses persist. This form of the disease is more likely to get well. Bruce has suggested "right lower quadrant" actinomycosis as being a more appropriate designation than cecal actinomycosis.

This tendency for the site of origin of the disease to heal completely is a well-known fact in the facial and cervical types of the disease. The patient usually contracts actinomycosis by chewing grain or grasses; the organism, *Actinomyces bovis,* lodges about the teeth, and when the diagnosis is apparent no trace of the disease can usually be seen within the mouth.

Recently a patient with an abscess of the tongue presented himself for examination at the University Hospital. It was first believed that this was an abscess of the unobliterated upper portion of the thyroglossal duct tract. Most primary abscesses of the tongue, however, are due to actinomycosis and when search was made for the organisms they were readily demonstrated.

The results of treatment of actinomycosis on the whole are unsatisfactory, due largely to the fact that most cases present themselves late for treatment. Sporotrichosis is the only fungus infection in which iodine is a specific. The actinomyces may grow in a solution of potassium iodid. Iodine given in large doses, however, appears to be of definite value. Good results in the cervico-facial type have been obtained with deep *x*-ray and radium treatment. In the early case, however, curettement or surgical excision appear to be measures of greater value. The local use of copper sulphate, as suggested by Dr. Bevan in the treatment of blastomycosis, is of no value.

Dr. E. A. Regnier recalled a case of abdominal actinomycosis in a woman whom he operated upon three years ago. The case was that of an appendiceal abscess, which was drained. The abdominal wound healed in three weeks. The patient returned three weeks later with high fever, and pain in the upper right quadrant. At this time a subphrenic abscess was drained by a two-stage operation. A large quantity of serosanguinous pus was removed. On the third day sulphur granules were recovered from the wound. The singular finding in this case was that the appendix, which was about one inch in diameter, was sectioned serially, and no signs of actinomycosis were found. Dr. Regnier said he had looked up the literature at that time and most writers were of the opinion that the disease was spread by contiguous infection. In his

own case, the first manifestation was the subphrenic abscess, which speaks for infection through the lymphatics. The infection never appeared in the abdominal wall, but multiple sinuses appeared in the dorso-lumbar region. In looking up the subject of therapy, he found that almost everything had been used. In Dr. Regnier's case, massive doses of deep *x*-ray, and potassium iodide by mouth, had been used but therapy had no effect on the progress of the disease.

Dr. A. T. Mann stated that he had seen two such cases and in both of them the discharge contained a fair number of these bodies; in fact the sulphur granules could be seen with the naked eye quite readily.

In regard to the character of the growth and the pathology, Dr. Mann stated that it is the result of an irritation of the tissues, a granuloma in its growth. There is more or less destruction of the cells immediately about the infecting fungus, followed by attracted leukocytes and the proliferation of granulation tissue round about it. As a rule it is very slow to produce pus. The streptothrix does produce pus at times and some of the granuloma breaks down, but a good many of the suppurations come from secondary infection in the area of these granulomata. One might be misled in making an early diagnosis because of the firmness of the enlargement, and think the case possibly a sarcoma.

As to the spread of infection, secondary infection, and so on, Dr. Mann said that it is most like a septic pyemia or like sarcoma in its secondaries. The granulations grow into the veins and produce a secondary involvement from small emboli mostly, just as the secondary infection from pyemia and from sarcoma.

Dr. Mann said that what had been stated tonight in regard to treatment he had found to be true when he was reading the literature on this subject. Many things had been tried, but potassium iodide seems to be considered more favorably than any other one thing. And while it is true, as Dr. Wangensteen stated, that the streptothrix will grow in a solution of 1 to 2 per cent potassium iodid, that is not all there is to medication. It may also do something toward stimulating the surrounding tissues or other groups of tissues, with resulting destruction of the stroptothrix.

Dr. Mann also called attention to the fact that although most of these infections are supposed to get in with some food, about 20 per cent of the cases are found in people who have cavities in the teeth and the streptothrix has been found in the teeth; in fact it is sometimes found in the teeth cavities when the actinomycosis is not active in the patient.

Another interesting feature is the number of cases of infection of the lungs, with symptoms simulating tuberculosis of the lungs, and in which the resulting deaths have been credited to tuberculosis.

Dr. Yoerg, in closing, stated that in Sanford's collection the larger percentage of cases were found in the upper Mississippi Valley. Various treatments had been tried; some had used salvarsan, and some had given yeast. This was the first abdominal case Dr. Yoerg had seen and it occurred to him that opening up the abdominal wall, curetting the sinuses and packing them would yield the best results. He thought the trouble lay deeper; that it was intra-abdominal and probably involved the veins of the hip and thigh.

Dr. R. C. Webb and Dr. E. R. Anderson reported a case of Abscess of the Liver Complicating Acute Appendicitis.

Dr. Webb presented the patient, a fifteen year old boy, on whom he had operated for ruptured appendix one year ago. He called attention to the scar of the appendicitis operation and stated that the drainage used was the Gibson tampon described by him before this Society in 1923. No sutures were used in the wound. Three weeks later it was necessary to make an upper right rectus incision and drain a liver abscess. He asked the members to notice the absence of hernia in the lower scar even though it was a very large wound without sutures. In the first operation it was the usual serious ruptured appendix case. Dr. Webb asked Dr. Anderson to read the case report and review of the literature. (The case to be published as a separate paper in Minnesota Medicine.)

DISCUSSION

Dr. J. A. Johnson said the doctors should be congratulated in having secured this boy's recovery. He had seen four cases of liver abscess secondary to appendicitis. They all died. In every one of them the liver was filled with miliary abscesses, some of which had broken down into larger abscesses. Dr. Johnson said he could not see how this type of liver infection could recover. This led him to believe that one should undoubtedly consider two types of liver abscess, *i. e.*, the miliary type with diffuse abscesses, which undoubtedly does not recover; and the other, perhaps the occasional one, with a single abscess, which does recover. He believes that surgery should be resorted to in these cases because without it the outcome is usually hopeless.

One point Dr. Johnson wished to stress in regard to aspirating liver abscess. Many years ago he was present at a postmortem in which the man had had a liver abscess aspirated. The pus was very thick and did not flow through the needle and several attempts had been made in different parts of the liver to find the abscess. At postmortem every place the needle had been inserted a new culture had been implanted and there was an abscess from each needle insertion. Since that time he had always been very careful, using very large needles, and always changing the needle each time a puncture is made in a different location.

Dr. W. P. Herbst, in discussing the matter of drainage of liver abscess, thought that the method of sewing the liver to the abdominal wall was probably one of the main factors in the recovery of the patient. He stated that some men, in draining liver infections, would sew the area around the abscess to the peritoneum of the abdominal wall, leaving the wound open and later opening the abscess when the infected area was walled off from the peritoneal cavity. Where the anatomical relationships do not allow this sort of procedure, the next best thing is to use large amounts of

iodoform gauze to form a walled-off area in the region of the abscess to prevent abdominal infection. The method is one of walling off the abdominal cavity.

Dr. Theodore Sweetser called particular attention to the importance of chills in raising the suspicion of possible liver abscesses. He also called attention to the good fortune in Dr. Webb's case, in that there was no infection of the portal vein system. In entering the liver, the infection evidently did so without a purulent infection of the veins, which of course would have made the case almost hopeless.

Dr. Leo Murphy thought it would be interesting to know whether the cases reported are based on single or multiple abscesses of the liver. He felt that Dr. Johnson's point was very pertinent as far as liver abscess is concerned.

Dr. Martin Nordland said that it would be natural to question what the surgeon could do to prevent an abscess of the liver when operating upon a case of suppurative appendicitis. He advised applying the ligature to the meso-appendix as far away from the appendix as possible, as suggested by Dr. Jackson. This would exclude the thrombi in the small veins.

Dr. Theodore Sweetser suggested, as a measure for the prevention of such disasters, that the meso-appendix be carefully observed in order to discover thrombosis of any veins, ligating beyond any thrombus found.

Dr. Wangensteen felt that the point raised by Dr. Sweetser with reference to the occurrence of chills in acute appendicitis was very significant. While a junior house officer at the Colonial Hospital in Rochester he recalled seeing a patient who gave this history early in the course of the disease. No special note was made of the chills by the surgeon in attendance. At operation a diffuse suppurative process without peritoneal extension was found. In the course of the disease, chills continued and the patient died. At autopsy a pylephlebitis and multiple abscesses in the liver were found.

The occurrence of chills is synonymous with the presence of bacteria in the blood stream and in acute appendicitis it signifies thrombosis of the mesenteriolum of the appendix. Professor Melchior of Breslau has performed a successful secondary operation when chills occurred in the immediate convalescence after appendectomy, ligating and excising the mesenteriolum of the appendix high in the ileocecal angle. Melchior states that about eight successful secondary operations of this nature are to be found in the literature.

Dr. Mann said he wished to call attention to one point in regard to statistics showing the high percentage of liver abscess after appendicitis operations in the old reports. He said that in those days cases of appendicitis did not usually get into the hospitals unless they had an abscess and almost every operation in those early days was a pus appendix. He believed if the later statistics could be revised, taking only the abscess cases, one might get figures nearer the older statistics. He felt that the real point in the mortality of these cases lay in the fact that there is an accompanying septicemia or there are multiple abscesses. He was of the opinion that if several abscesses were close together and they could be broken down with the finger into one cavity and drained they might recover, but if there were multiple abscesses and some were not drained they are more likely to be fatal.

Dr. Webb, in closing, thanked the members for their generous discussion of the case. The boy had presented the usual appearance of a case of appendicitis, such as all the members had seen, and was one which was apparently going to die. The operation was performed as a rather extreme measure in this case, but Dr. Webb felt that, after seeing this boy and hearing the discussions of the case, the members would all have more courage to operate upon and drain these liver abscess cases earlier and more frequently than they had before.

Dr. Anderson, in closing, discussed some of the things which might be done to prevent liver abscess and stated that Wilms resected the veins that were thrombosed in the ileocecal angle and had cases of recovery. Braun ligated the ileocolic vein and has reported successful cases. Colp of New York experimented with gradual ligation of the portal vein in dogs and they lived. He tried the same procedure on three patients who had an extreme grade of thrombopylephlebitis and had been unsuccessful in obtaining recoveries. This was discussed to a greater extent in the paper under the section on treatment, the reading of which was omitted on account of the time limit.

Dr. Oswald S. Wyatt read his Thesis entitled "Congenital Hypertrophic Pyloric Stenosis." (To be published at a later date in Minnesota Medicine.)

DISCUSSION

Dr. Willard White stated that he had enjoyed this paper very much and there were two or three points he wanted to mention. He called attention to Dr. Wyatt's method of making an incision through the hypertrophied muscle and then continuing by spreading with forceps, but Dr. White felt that using the blunt end of the scalpel furnished a safe way to accomplish this and avoided opening the mucous membrane. He believed it advisable to close the abdominal wound with mattress sutures tied through buttons, especially if the infant was in poor condition and one wished to save time. He felt that the use of buttons was a very great advantage as the sutures would hold securely and there was very much less cutting of the skin by the sutures.

Dr. White felt that the conservation of heat during the time of operation is also an important factor, and the infant should not only be wrapped in cotton batting but the batting should previously be warmed in some kind of warming device and, in addition, hot water bottles should be kept around the infant during the time of operation.

Dr. White was of the opinion that there is very much less objection to general anesthesia in these operations than is often thought. One hears much emphasis placed on local anesthesia, and that is all right, but one's strategy is very important in these cases and un-

less the operator is very careful in the use of local he may cause pain and resulting shock; and in the avoidance of shock, Dr. White felt that general anesthetic is preferable.

Dr. Green asked Dr. Wyatt what he thought of the Strauss method of technic in the cases where a muscle flap is used to cover over the mucous membrane. Dr. Green said when he was in Chicago he heard Dr. Strauss discuss his operation at some length and also saw him do an operation. It seemed to Dr. Green that the benefit derived was hardly worth the extra time and trouble as compared to the Rammstedt operation, and he would like to have Dr. Wyatt's opinion about it.

Dr. Theodore Sweetser brought up a point which had been stressed by Dr. R. E. Farr in discussing this subject some years ago and which also had been called very strongly to his own attention in a case he happened later to see in one of the hospitals. In the latter case the baby was given ether anesthesia before the surgeon and his assistant were ready to operate, so that the baby was exposed to the anesthetic an unnecessarily long period of time. That might have been avoided under local anesthesia. If the operation is to be done under general anesthesia, everything in the operating room should be so arranged as to avoid unnecessary delay after the child is put to sleep.

Dr. Wyatt, in closing, said that he was familiar with the Strauss method of operation as mentioned by Dr. Green, but that he had never used it himself as he had had such very good results with the Rammstedt operation that he had not tried any other. In reading up on the Strauss operation, Dr. Wyatt was under the impression that it would take a little more time and he had not thought it advisable to use it.

The meeting adjourned.

H. O. McPheeters, M.D., *Secretary.*

CONSULTATION BUREAU

(Continued from Page 918)

can suggest as to treatment will be appreciated. There are several ulcers now with punctuate cloudy spots in the cornea. Eye still red and congested, painful to the extent of interfering with sleep. Reported less painful today.

Answer.—1. From the description one would gather that the injection of the eye is secondary to the ulceration of the cornea. If this is the case the line of treatment is quite different than it would be had the ulcer resulted as a complication of the conjunctivitis. In primary marginal ulcers of the cornea one can usually trace the cause to a focus of infection somewhere in the system. It may also be due to conditions such as diabetes. Ulcers of this type are slow in healing and recurrences are frequent. The treatment usually prescribed is removal of the focus and putting the patient in the best physical condition possible. If pus is absent, put the eye at rest by keeping the lid closed. The movement of the lid tends to aggravate the condition. Bichloride ointment 1–5,000 should be applied twice daily. If, after a few days, improvement does not take place, the eye should be anesthetized with butyn and each ulcer touched with absolute alcohol, care being taken not to touch normal corneal tissue. Atropine should be used. Warm applications may be made to the eye for fifteen minutes three times a day. Dark glass over the good eye will lessen the photophobia. If the above measures do not cause healing, the thermaphore should be used. Some cases respond well to foreign protein injections, such as 5 c.c. of boiled milk. If the ulcer is secondary to the conjunctival inflammation, foreign protein therapy is advisable. The eye should be irrigated frequently with warm metaphen solution 1–5,000. The patient should be put at rest. The ulcers touched with absolute alcohol if healing does not take place. Silver nitrate 2% applied to the lids following an application of butyn is beneficial.

2. It would appear from the history of this case that the patient has a probably mycotic ulcer of the cornea. These mycotic infections are usually due to aspergillus, coming from organic foreign bodies, particularly grain. Extensive examination by smears would be advisable. The condition of the conjunctiva of the lids is not mentioned. Here, too, is a possibility of irritation of the cornea, secondary to lid involvement. If the ulcer continues to resist treatment, as outlined, I would suggest trying cautery with phenol or tincture of iodine, or the possibility of putting a Kundt flap of conjunctival over the ulcerated area.

THE ADVERTISING OF THE DENTIFRICE

The early part of the twentieth century may be interesting historically for the fact that it witnessed the apotheosis of the tooth brush, the tooth paste and the mouth wash. So far as mouth washes are concerned, their virtues may lie in a slight astringency or alkalinity, in the mildly antiseptic influence they exert for a brief period, or more probably in the fact that they contain enough water to provide a lavage appealing to the organoleptic senses. "Halitosis" gave to Listerine a sales impulse that no other mouth wash has ever been able to equal. The fact that the combination of substances included in Listerine is relatively ineffective and will not cure halitosis did not lessen the sales impulse. Recently, the Food and Drug Administration has cast a critical eye over the claims for antiseptic value made for various mouth washes and gargles. It is currently reported that the owners of all these bringers of gold are rushing hither and thither to the laboratories searching for substances that really are antiseptics and that can be added to their concoctions without changing taste or color—the important qualities—that the claims may be justified. Recently, dentifrices have been widely exploited with various claims. A half dozen assorted chemists and the commissioner of health of New York assert that low surface tension means that a tooth paste will penetrate better between the teeth. The claim of special value because of low surface tension in connection with the selling of any tooth paste is one hundred per cent hokum. Any mixture of soap, glycerin and chalk, such as is available in many tooth pastes, would be equally endowed with a low surface tension. The council on dental therapeutics of the American Dental Association is now making efforts to secure restriction of the claims for dentifrices and physicians should do all that they can to aid the American Dental Association in this campaign. (Jour. A. M. A., October 25, 1930, p. 1267.)

PROGRESS

Abstracts to be submitted to Section Supervisors.

Members are urged to abstract valuable articles which they run across in their reading and send the abstracts to the physicians in charge of the respective sections. In order to avoid duplication it would be well to communicate with one of the section supervisors before the article is abstracted.

EYE, EAR, NOSE AND THROAT

THE FREQUENCY OF MASTOIDITIS IN INFANTS: T. C. Helwig and O. J. Dixon, M.D. (Arch. of Otolaryng., Feb., 1930, p. 1). Much controversy has arisen regarding the relationship between mastoiditis and acute nutritional disturbances in infants. The contention of most investigators has been that the ear infection acted as the primary focus and that the enteric disturbance was secondary. The result has been a marked increase in the number of ear drums lanced and mastoids operated on.

The authors were struck by the fact that in a series of 173 necropsies on patients from both the pedriatric and the otologic services, they encountered fifty-seven cases in which changes were present either in the middle ear or in the mastoid or in both.

A careful study of these 57 cases (or 32.8%) was made in an effort to determine the relationship of mastoiditis to enteritis.

Only seventeen of these fifty-seven cases showed evidence of enteric infection, while the remaining forty represented almost every common disease of infancy. The case reports show the incidence of ear and mastoid infection to be much higher in the non-enteric than in the enteric group. A careful study shows that the histologic observations fit in rather accurately with the clinical findings, and in every case the history of diarrhea antedated the ear infection.

(1) In the usual fatal illnesses of infants ear infection is a common terminal event. (2) Enteritis, as shown by necropsy, too frequently antedates the ear infection for one to assume that the latter is primary. (3) The mortality rate of these infants coming to operation has been high and distinctly out of proportion to the usual mortality rate. From this study, one concludes that although surgical mastoiditis does occur in infants, its importance has been vastly overrated.

Gerald M. Koepcke, M.D.

PEDIATRICS

PRACTICAL VALUE OF IMMUNIZATION AGAINST SCARLET FEVER WITH STREPTOCOCCUS TOXIN: T. Toyoda, J. Moriwaka, Y. Futagi and M. Okamoto. (Jour. Infect. Diseases, 46-219, March, 1930). The authors found after immunization with up to 40,000 skin test doses of the Dick toxin that over fifteen per cent of the individuals remained Dick-positive. These positive reactions were ascribed to production of allergy to the heat-stable component of the Dick toxin. On retesting this positive group with heat-labile toxin, which they consider to indicate actual immunity, these positive reactions were found to be negative. By means of prophylactic immunization of 3,197 children with the Dick toxin the scarlet fever incidence was reduced to one forty-third the rate prevalent among the unimmunized. Cases of scarlet fever occurred in children after immunization but were generally mild. The authors feel, therefore, that immunization against scarlet fever by means of the Dick toxin is of value provided 30,000 or more skin test doses are administered to make the immunization thorough. Some difficulty was encountered in systemic reactions to the naked Dick toxin. These reactions were reduced through the use of toxin detoxified by treatment with 0.4 per cent formaldehyde according to the method used by Ramon for detoxifying diphtheria toxin. The scarlet fever anatoxin prepared by treating the Dick toxin with formaldehyde and heated to 48° C. has its toxicity sufficiently reduced to render possible the administration of large amounts of the toxin without causing reactions. Anatoxin prepared in this manner, however, loses some of its effectiveness in rendering the individual immune as indicated by skin test, due possibly to a reduction in its antigenic power from the high temperature at which the anatoxin is prepared.

C. A. Stewart, M.D.

BOOK REVIEWS

Books listed here become the property of the Ramsey and Hennepin County Medical libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

PRIMER ON FRACTURES. Price $I. Chicago, American Medical Association, 1930.

The increased interest shown in fractures led in 1926 to the appointment of a committee consisting of Drs. Nathaniel Allison, William Darrach and Kellogg Speed by the Surgical Section of the A. M. A. to prepare an exhibit of accepted methods for treating the various common fractures for inclusion in the scientific exhibit at the annual A. M. A. meetings. This exhibit, which has been offered at the last four annual meetings excited such interest that the material presented has been put in book form and published by the A. M. A. at a very reasonable price. The book is well illustrated, brief and worth much more than the price would indicate.

OSLER'S PRINCIPLES AND PRACTICES OF MEDICINE. Revised by T. McCrae. 11th Edition. Price $8.50. New York and London: Appleton and Co., 1930.

This latest edition continues to hold the place of its predecessors as the best one-volume work on the subject. Exteriorly its appearance is the same as the earlier editions, but the contents show the results of a painstaking revision, which brings all the sections thoroughly up to date. One of the most valuable assets of the volume is the index, which has been prepared with unusual care and thoroughness.

HARRY OERTING, M.D.

WANTED—Salaried appointments for Class A Physicians in all branches of the medical profession. Let us put you in touch with the best man for your opening. Our nation-wide connections enable us to give superior service. Aznoe's National Physicians' Exchange, 30 North Michigan Ave., Chicago. Established 1896. Member The Chicago Association of Commerce.

PHYSICIAN'S OFFICE FOR RENT—Best location Midway district, corner Thomas and Hamline, Saint Paul. Rent $25.00 a month. Inquire at dentist's office.

WANTED—Physician to do locum tenens work for January and February. Everything furnished. Recent graduate preferred. Address D-114, MINNESOTA MEDICINE.

WANTED—Position as physician's office assistant and clinic laboratory and X-ray technician by experienced stenographer with technician's training. Address D-110, care MINNESOTA MEDICINE.

POSITION WANTED: Woman *x*-ray technician, age 29, completed nine months' training in *x*-ray technic and four months' hospital emergency experience at General Hospital, Minneapolis, Minnesota. Address D-115, care MINNESOTA MEDICINE.

WANTED—Physician to share nicely furnished office, reception and examining rooms with light and telephone, $30 monthly. 302 Lowry Building, Saint Paul, Minnesota.

LOCATION OPEN for a dentist in Minneapolis, rooms next to a physician and surgeon. Only Gentiles considered. Act quickly. Address D-112, care of MINNESOTA MEDICINE.

FOR SALE—Stock including Hanovia Sun Lamps, Diathermy, Surgical Instruments, Microscopes and other equipment for sale at a sacrifice. Sophia Hein, Executrix, Estate of Frederick Hein, 219 South Lexington Avenue, Saint Paul, Minnesota.
